Because of the high coefficient of thermal expansion of copper the root gap has a tendency to close up as welding proceeds, and due to its high thermal conductivity pre-heating from 400–700 °C according to thickness is essential on all but the thinnest sections to obtain a good molten pool. The thermal conductivity of most of the copper alloys is much lower than copper so that pre-heating to about 150 °C is usually sufficient. In the range 400–700 °C a reduction in ductility occurs in most of the alloys so that a cooling period should be allowed between runs. The main grades of copper are (1) tough pitch (oxygen containing) high conductivity, (2) oxygen free, high conductivity, (3) phosphorus deoxidized, and in most cases it is the last type that is used for pressure vessels, heat exchangers and food processing equipment, etc. If tough pitch copper, in the cast form, is to be welded, a deoxidizing filler rod should be used to give a deoxidized weld and in all cases the weld should be performed as quickly as possible to prevent overheating.

Argon, helium and nitrogen can be used as shielding gases. Argon has a lower heat output than helium and nitrogen because it has a lower arc voltage. Argon can be mixed with helium and the mixture increases the heat output proportionally with the helium percentage, so that using the mixture for copper welding a lower pre-heat input is required and

penetration is increased. Nitrogen gives the greatest heat output but although the welds are sound they are of rough appearance.

Recommended filler alloys are:

C7 0.05–0.35% Mn, 0.2–0.35% Si, up to 1.0% Sn, remainder Cu.
C8 0.1–0.3% Al, 0.1–0.3% Ti, remainder Cu.
C21 0.02–0.1% B, 99.8% Cu.

Note. Filler alloys for copper and its alloys are to BS 2901, Pt 3, 1970.

Copper–silicon (silicon bronzes). d.c. supply, electrode negative and argon (or helium) shield. These alloys contain about 3% silicon and 1% manganese. They tend to be hot short in the temperature range 800–950 °C so that cooling should be rapid through this range. Too rapid cooling, however, may promote weld cracking.

Filler alloy C9, 96% Cu, 3% Si, 1% Mn is recommended.

Copper–aluminium (aluminium bronzes). a.c. with argon shield or d.c. with helium shield. The single phase alloys contain about 7% Al and the two phase alloys up to 11 % Al with additions of Fe, Mn and Ni. Welding may affect the ductility of both types. Weld root cracking in the 6–8% Al, 2–2.3% Fe alloy used for heat exchangers can be avoided by using a non-matching filler rod. Due to a reduction in ductility at welding temperatures difficulty may be experienced in welding these alloys. The alloy containing 9% Al and 12% Mn with additions of Fe and Ni has good weldability but requires heat treatment after welding to restore corrosion resistance and other mechanical properties.

Recommended filler alloys are:

C12 6.0–7.0% Al, remainder Cu.
C13 9.0–11.0% Al, remainder Cu.
C20 8.0–10.0% Al, 1.5–3.5% Fe, 4.0–7.0% Ni, remainder Cu.

Copper–nickel (cupro–nickels). d.c. with argon shield and electrode negative. These alloys, used for example for pipe work and heat exchangers, contain from 5 to 30% Ni, often with addition of Fe or Mn to increase corrosion resistance. They are very successfully welded by both TIG and MIG processes but since they are prone to contamination by oxygen and hydrogen, an adequate supply of shielding gas must be used including a back purge in certain cases, if possible.

Recommended filler alloys are:

C17 19–21% Ni, 0.2–0.5% Ti, 0.2–1.0% Mn, remainder Cu.
C19 29–31% Ni, 0.2–0.5% Ti, 0.2–1.0% Mn, remainder Cu.

Copper–tin (phosphor bronzes and gunmetal), d.c. with argon shield. The wrought phosphor bronzes contain up to 8% Sn with phosphorus additions up to 0.4%. Gunmetal is a tin bronze containing zinc and often some lead. Welding of these alloys is most often associated with repair work using a phosphor bronze filler wire but to remove the danger of porosity, non-matching filler wires containing deoxidizers should be used.

Filler alloys recommended are:

C10 4.5–6.0% Sn, 0.4% P, remainder Cu.
C11 6.0–7.5% Sn, 0.4% P, remainder Cu.

Copper–zinc (brass and nickel silvers), a.c. with argon shield, d.c. with helium shield. The copper–zinc alloys most frequently welded are Admiralty brass (70% Cu, 29% Zn, 1% Sn), Naval brass (62% Cu, 36.75% Zn, 1.25% Sn) and aluminium brass (76% Cu, 22% Zn, 2% Al). Porosity, due to the formation of zinc oxide, occurs when matching filler wire is used so that it is often preferable to use a silicon–bronze wire which reduces evolution of fumes. This may, however, induce cracking in the HAZ. Post-weld stress relief in the 250–300 °C range reduces the risk of stress corrosion cracking. The range of nickel silver alloys is often brazed.

Filler alloys recommended are:

C14 70–73% Cu, 1.0–1.5% Sn, 0.02–0.06% As.
C15 76–78% Cu, 1.8–2.3% Sn, 0.02–0.06% As.

Work-hardening and precipitation-hardening copper-rich alloys

The work-hardening alloys are not often welded because mechanical properties are lost in the welding operation. Heat-treatable alloys such as copper–chromium and copper–beryllium are welded with matching filler rods using an a.c. supply to disperse the surface oxides. They are usually welded in the solution-treated or in the over-aged condition and then finally heat-treated.

Hardfacing

The tungsten arc is a good method for deposition of stellite and other hard surfacing materials on a base metal. The heat is more concentrated than that of the oxy-acetylene flame and although there may be some base metal pick-up this can be kept to a minimum by using correct technique and there is not a great deal of dilution. It produces a clean, sound deposit and is very useful for reactive base metals.

The electrode is connected to the –ve pole (straight polarity) with the largest diameter filler rod possible to reduce tungsten contamination. Deposition is similar to that when the oxy-acetylene flame is used and deposition moves from right to left. Filler rods of 3.2, 4.0, 4.8, 6.4 and 8 mm are available and alloys include stellite and nickel-based alloys, and deposition proceeds in the normal way for hard surfacing – do not puddle the pool as this increases dilution.

Easily hardfaced

Low and medium carbon steel to 0.4% C. Above 0.4% C, oxy-acetylene only.

Low-alloy steels.

Nickel and nickel–copper alloys.

Chrome–nickel stainless steels, niobium stabilized. (Not free machining nor titanium stabilized).

11–14% manganese steels.

More difficult to hardface

Cast iron.

Stainless steel, straight and titanium stabilized.

Tool and die steels, water-hardening, oil-hardening and air-hardening types and hot work grade.

Straight chromium stainless steels.

Automatic welding

For automatic welding the TIG torch is usually water cooled and may be carried on a tractor moving along a track or mounted on a boom so as to move over the work or for the work to move under the head. The head has a control panel for spark starter, water and gas and current contactor, and the torch has lateral and vertical movement, the arc length being kept constant by a motor-driven movement controlled by circuits operating from the arc length. Filler wire is supplied from the reel to the weld pool by

TIG process. Recommended filler wires for copper welding

		Filler wire	
Type (BS 2870–2875)	Grade	Argon or helium shield	Nitrogen shield
C106	Phosphorus deoxidized non-arsenical	C7, C21	C8
C107	Phosphorus deoxidized arsenical		
C101	Electrolytic tough pitch high conductivity	C7, C21	Not recommended
C102	Fire-refined tough pitch high conductivity		
C103	Oxygen-free high conductivity	C7, C21	Not recommended

rollers driven by an adjustable speed motor. Heavier currents can be used than with manual operation resulting in greater deposition rates, and the accurate control of speed of travel and arc length results in welds of high quality. Plate up to 9 mm thick can be welded in one run, the welding being of course downhand. Fig. 3.29 illustrates a typical tractor-driven head.

Orbital pipe welding unit

This can operate from a standard TIG power source and enables circumferential joints on pipes and tubes to be made automatically. It is of caliper type enabling rapid adjustments to be made, and rotational drive is by a small motor mounted in the handle of the unit, rotational speed being controlled by transistor regulator. A wire feed unit feeds wire to the arc, the feed speed of the wire being controlled by a thyristor regulator. Three sizes are available for pipes with outside diameters of 18–40, 36–80 and 71–160 mm (Fig. 3.30).

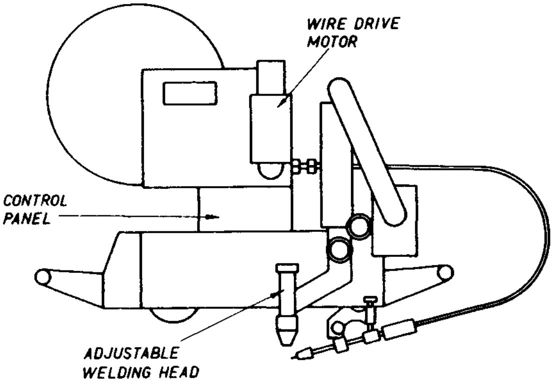
Mechanized TIG hard facing

In this process the argon shielded TIG arc oscillates over a width from 6 to 25 mm and is operated by variable controls for speed and width. Rod and torch also have controls for vertical height and horizontal positioning and for feeding the hard surfacing rod.

Small quantities of hydrogen are added to the argon by means of a gas blender to give a more consistent deposit. The stellite alloy, in rod form, can be laid on large circular components of 100–600 mm diameter and this is ideal for valves and valve seatings, rings and sleeves, etc., the work being mounted on a manipulator.

A smaller system enables components from 25–220 mm diameter to be hard faced. The unit can be adapted for flat straight working if required and the usual power unit for TIG welding is required. A complete range of hard facing alloys is available.

Fig. 3.29. Automatic TIG welding head mounted on electrically driven tractor; 500 A water cooled torch.



TIG robot welding

TIG welding has now been applied to the robot system with two manipulators. In this method of welding the workpieces are held in jigs on the plates of the manipulators, one being welded while the other is being loaded. The six axes of the robot enable it to handle the filler wire and place it in the best position without limitation of the wrist movement of the robot.

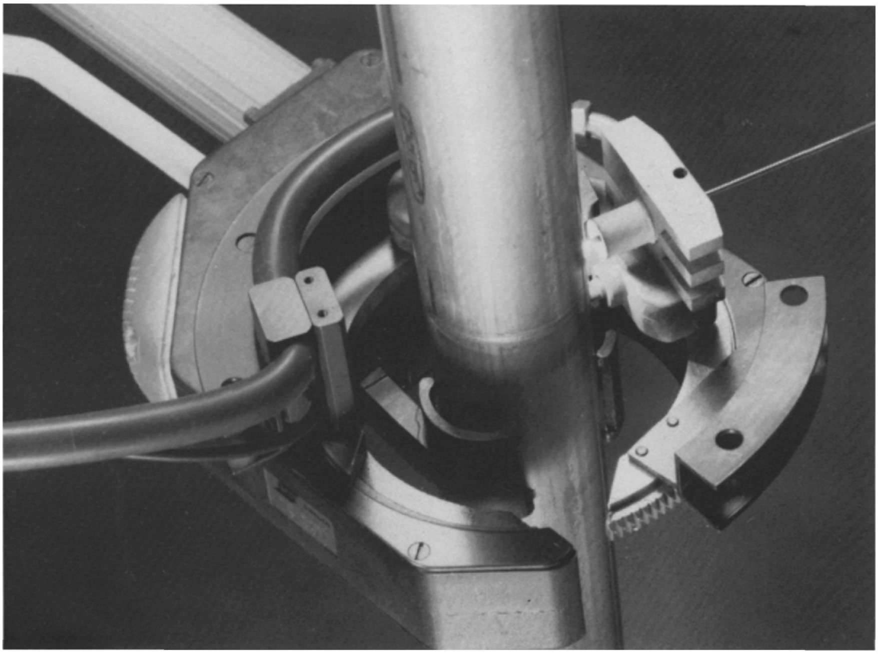
Since the HF necessary for the arc initiation may cause unwanted signals to the microprocesser all conductors have been screened. The control computer selects and records the particular welding program and together with the robot achieves synchronized movements, and welding operations are commenced when the operator has loaded one of the two manipulators of the system. (See Chapter 5, Welding with robots, for illustration of this system.)

Various parameter sequences for various operations can be pre-recorded and recalled as required.

Spot welding

Mild steel, stainless and alloy steel and the rarer metals such as titanium can be spot welded using a TIG spot welding gun. The pistol grip water cooled gun carries a collet assembly holding a thoriated tungsten electrode positioned so that the tip of the electrode is approximately 5 mm

Fig. 3.30. Orbital TIG pipe welding.



within the nozzle orifice, thus determining the arc length. Interchangeable nozzles enable various types of joints to be welded flat, or vertically. A variable timing control on the power unit allows the current to be timed to flow to ensure fusion of the joint and a switch on the gun controls gas, water, HF unit and current contactor. To make a weld, the nozzle of the gun is pressed on to the work in the required position and when the gun switch is pressed the following sequence occurs: (1) gas and water flow to the gun, (2) the starter ignites the arc and the current flows for a period controlled by the timer, (3) current is automatically switched off and post-weld argon flows to cool electrode tip and weld.

Note. Refer also to BS 3019, *General recommendations for inert gas, tungsten arc welding*, Part 1: *Wrought aluminium, aluminium alloys and magnesium alloys*, Part 2: *Austenitic stainless and heat resisting steels.*

Titanium

Titanium is a silvery coloured metal with atomic weight 47.9, specific gravity 4.5 (cf. Al 2.7 and Fe 7.8) melting point 1800°C and UTS 310 N/mm^2 in the pure state. It is used as deoxidizer for steel and sometimes in stainless steel to prevent weld decay and is being used in increasing amounts in the aircraft and atomic energy industries because of its high strength-to-weight ratio.

Titanium absorbs nitrogen and oxygen rapidly at temperatures above 1000°C and most commercial grades contain small amounts of these gases; the difficulty in reducing the amounts present makes titanium expensive. Because of this absorption it can be seen that special precautions have to be taken when welding this metal.

Where seams are reasonably straight a TIG torch with tungsten electrode gives reasonable shrouding effect on the upper side of the weld, and jigs may be employed to concentrate the argon shroud even more over the weld. In addition the underbead must be protected and this may be done by welding over a grooved plate, argon being fed into this groove so that a uniform distribution is obtained on the underside. It can be seen therefore that the success of welding in these conditions depends upon the successful shrouding of the seam to be welded.

For more complicated shapes a vacuum chamber may be employed. The chamber into which the part to be welded is placed is fitted with hand holes, and over these are bolted long-sleeve rubber gloves into which the operator places his hands, and operates the TIG torch and filler rod inside the chamber. An inspection window on the sloping top fitted with welding glass enables a clear view to be obtained. All cable entries are sealed tightly and the air is extracted from the chamber as completely as possible by pumps, and the chamber filled with argon, this being carried out again if necessary to get the level of oxygen and nitrogen down to the lowest permissible level. The welding may be performed with a continuous flow of argon through the chamber or in a static argon atmosphere. Since the whole success of the operation depends upon keeping oxygen and nitrogen levels down to an absolute minimum great care must be taken to avoid leaks as welding progresses and to watch for discoloration of the weld indicating absorption of the gases.

Tantalum

Tantalum is a metallic element of atomic weight 180.88, HV 45, melting point 2910 °C, specific gravity 16.6, it is a good conductor of heat and is used in sheet form for heat exchangers, condensers, small tubes, etc. Like titanium it readily absorbs nitrogen and oxygen at high temperatures and also readily combines with other metals so that it is necessary to weld it with a TIG torch in a vacuum-purged argon chamber as for titanium.

Beryllium

Beryllium is a light, steely coloured metallic element, atomic weight 9, melting point 1280–1300 °C, specific gravity 1.8, HV 55–60. It is used as an alloy with copper (beryllium bronze) to give high strength with elasticity. As with tantalum and titanium it can be welded in a vacuum-purged argon chamber using a TIG torch. It can also be pressure welded and resistance welded.

Electron beam welding is now being applied to the welding of the rare metals such as the foregoing, in the vacuum chamber. A beam of electrons is concentrated on the spot where the weld is required. The beam can be focused so as to give a small or large spot, and the power and thus the heating effect controlled. Successful welds in a vacuum-purged argon chamber are made in beryllium and tantalum.

*Plasma-arc welding (plasma welding)**

Plasma welding is a process which complements, and in some cases is a substitute for, the TIG process, offering, for certain applications, greater welding speed, better weld quality and less sensitivity to process variations. The constricted arc allows lower current operation than TIG for similar joints and gives a very stable controllable arc at currents down to 0.1 A, below the range of the TIG arc, for welding thin metal foil sections. Manual plasma welding is operated over a range 0.1–100 A from foil to 3–4 mm thickness in stainless steel, nickel and nickel alloys, copper, titanium and other rare earth metals (not aluminium or magnesium).

---

* American designation: plasma-arc welding (PAW).

Ions and plasma

An ion is an atom (or group of atoms bound into a molecule) which has gained or lost an electron or electrons. In its normal state an atom exhibits no external charge but when transference of electrons takes place an atom will exhibit a positive or negative charge depending upon whether it has lost or gained electrons. The charged atom is called an ion and when a group of atoms is involved in this transference the gas becomes ionized.

All elements can be ionized by heat to varying degrees (thermal ionization) and each varies in the amount of heat required to produce a given degree of ionization, for example argon is more easily ionized than helium. In a mass of ionized gas there will be electrons, positive ions and neutral atoms of gas, the ratio of these depending upon the degree of ionization.

A plasma is the gas region in which there is practically no resultant charge, that is, where positive ions and electrons are equal in number; the region is an electrical conductor and is affected by electric and magnetic fields. The TIG torch produces a plasma effect due to the shield of argon and the tungsten arc but a plasma jet can be produced by placing a tungsten electrode centrally within a water-cooled constricted copper nozzle. The tungsten is connected to the negative pole (cathode) of a d.c. supply and the nozzle to the positive pole (anode). Gas is fed into the nozzle and when an arc is struck between tungsten electrode and nozzle, the gas is ionized in its passage through the arc and, due to the restricted shape of the nozzle orifice, ionization is greatly increased and the gas issues from the nozzle orifice, as a high-temperature, high-velocity plasma jet, cylindrical in shape and of very narrow diameter realizing temperatures up to 10000°C. This type is known as the non-transferred plasma (Fig. 3.31*a*). With the transferred arc process used for welding, cutting and surfacing, the restricting orifice is in an inner water-cooled nozzle within which the tungsten electrode is centrally placed. Both work and nozzle are connected to the anode and the tungsten electrode to the cathode of a d.c. supply (in American terms, d.c.s.p., direct current straight polarity). Relatively low plasma gas flow (of argon, argon–helium or argon–hydrogen) is necessary to prevent turbulence and disturbance of the weld pool, so a further supply of argon is fed to the outer shielding nozzle to protect the weld (Fig. 3.31*b*). In the lead from work to power unit there is a contactor switch as shown.

A high-frequency unit fed from a separate source from the mains supply initiates the pilot arc and the torch nozzle is positioned exactly over the work. Upon closing the contactor switch in the work-to-power unit connexion, the arc is transferred from electrode to work via the plasma. Temperatures up to 17000 °C can be obtained with this arc. To shape the arc two auxiliary gas passages on each side of the main orifice may be included in the nozzle design. The flow of cooler gas through these squeezes the circular pattern of the jet into oval form, giving a narrower heat-affected zone and increased welding speed. If a copper electrode is used instead of tungsten as in the welding of zirconium, it is made the anode. The low-current arc plasma with currents in the range 0.1–15 A has a longer operating length than the TIG arc, with much greater tolerance to change

in arc length without significant variation in the heat energy input into the weld. This is because it is straight, of narrow diameter, directional and cylindrical, giving a smaller weld pool, deeper penetration and less heat spread whereas the TIG arc is conical so that small changes in arc length have much more effect on the heat output. Fig. 3.32 compares the two arcs. Since the tungsten electrode is well inside the nozzle (about 3 mm) in plasma welding, tungsten contamination by touchdown or by filler rod is avoided, making welding easier.

Equipment. In the range 5–200 A a d.c. rectifier power unit with drooping characteristic and an OCV of 70 V can be used for argon and argon–hydrogen mixtures. If more than 5% hydrogen is used, 100 V or more is required for pilot arc ignition. This arc may be left in circuit with the main arc to give added stability at low current values. Existing TIG power sources such as that in Fig. 3.11 may be used satisfactorily, reducing capital cost, the extra equipment required being in the form of a console placed on or near the power unit. Input is 380–440 V, 50 Hz, a.c. single-phase with approximately 3.5 A full load current. It houses relays and solenoid valves controlling safety interlocks to prevent arc initiation unless gas and water pressures are correct; flowmeters for plasma and shielding gases, gas purge and post-weld gas delay and cooling water controls. For low-current welding in the range 0.1–15 A, often referred to in Europe as micro-plasma and in America as needle plasma welding, the power unit is about 3 KVA, 200–250 V, 50 Hz single-phase input, fan cooled with OCV of 100 V nominal and 150 V peak d.c., for the main arc, and output current ranges 0.1–2.0 A and 1.0–15 A. The pilot arc takes 6A at 25 V start and 2.5 A at 24 V running, the main arc being cylindrical and only 0.8 mm wide. Tungsten electrodes are 1.6, 2.4 and 3.2 mm diameter, depending upon application.

Gases. Very pure argon is used for plasma and shield (or orifice) when welding reactive metals such as titanium and zirconium which have a strong affinity for hydrogen. For stainless steel and high-strength nickel alloys argon, or argon–hydrogen mixtures are used. Argon–5% hydrogen mixtures are applied for this purpose (cylinders coloured blue with a wide red band around the middle) and argon–8% hydrogen and even up to 15% hydrogen are also used. With these mixtures the arc voltage is increased giving higher welding speeds (up to 40% higher) and the thin oxide film present even on stainless and alloy steels is removed by hydrogen reduction giving a clean bright weld, and the wetting action is improved. For copper, nickel and their alloys argon is used in keyhole welding (Fig. 3.33) for thinner sections, for both orifice and shielding gas. Argon and helium is used in the melt-in welding of thinner sections and helium for orifice and shielding gas for sections over 3 mm thick.

De-ionized cooling water should be used, and gas flow rates at 2.0 bar pressure are about 0.25–3.3 litres per minute plasma and 3.8–7 litres per minute shielding in the 5–100 A range. Cleaning and preparation are

similar to those for TIG, but when welding very thin sections, oil films or even fingerprints can vary the degree of melting, so that degreasing should be thorough and the parts not handled in the vicinity of the weld after cleaning.

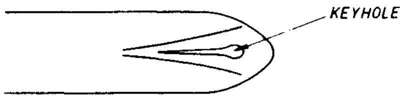
Technique. Using currents of 25–100 A, square butt joints in stainless steel can be made in thicknesses of 0.8–3.2 mm with or without filler rod, the angle of torch and rod being similar to that for TIG welding. The variables are current, gas flow and welding rate. Too high currents may break down the stabilizing effect of the gas, the arc wanders and rapid nozzle wear may occur. In 'double arcing' the arc extends from electrode to nozzle and then to the work. Increasing plasma gas flow improves weld appearance and increases penetration, and the reverse applies with decreased flow. A turbulent pool gives poor weld appearance.

In 'keyhole' welding of thicknesses of 2.5–6.5 mm a hole is formed in the square-edge butt joint at the front edge of the molten pool, with the arc passing through the section (Fig. 3.33). As the weld proceeds, surface tension causes the molten metal to flow up behind the hole to form the welding bead, indicating complete penetration, and gas backing for the underbead is required. When butt welding very thin sections, the edges of the joint must be in continuous contact so that each edge melts and fuses into the weld bead. Separation of the edges gives separate melting and no weld. Holding clamps spaced close together near the weld joint and a backing bar should be used to give good alignment, and gas backing is recommended to ensure a fluid pool and good wetting action. Flanging is recommended for all butt joints below 0.25 mm thickness and allows for greater tolerance in alignment. In the higher current ranges joints up to 6 mm thick can be welded in one run. Lap and fillet welds made with filler rod are similar in appearance and employ a similar technique to those made with the manual TIG process. Edge welds are the best type of joint for foil thickness, an example being a plug welded into a thin-walled tube.

In tube welding any inert gas can be used within the tube for underbead protection.

Faults in welding very thin sections are: excessive gaps which the metal cannot bridge; poor clamping allowing the joint to warp; oil films varying the degree of melting; oxidation or base metal oxides preventing good

Fig. 3.33. Surface tension causes molten metal to flow and close keyhole.



'wetting'; and nicking at the ends of a butt joint. This latter can be avoided by using run-off plates or by using filler rod for the start and finish of the weld.

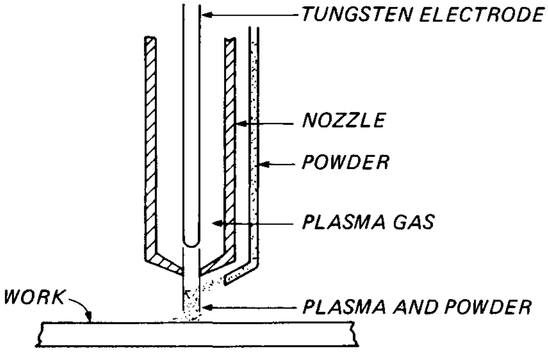
Plasma spray hard facing

In this method the arc plasma melts the hard facing powder particles and the high-velocity gas stream carries the molten particles on to the surface (Fig. 3.34). Although there may be some voids caused, 90–95% densities can be obtained and the method is particularly suitable for applying refractory coatings because this method has a better bond with the parent plate than the spray and fuse method. Because the heat is localized, surfaces can be applied to finished parts with no distortion and the finish is very smooth. The cobalt, nickel- and tungsten-based powders are all supplied for this process and suitable applications are gas turbine parts, such as sealing rings of gas turbines, mixer and feed parts, sleeves, sheets and wear pads and slides, etc.

Plasma transferred arc hardfacing

This powder deposition process is fully automated and uses a solid state SCR, the power output being 300 A, 32 V, at 100% duty cycle. The pilot arc is initiated by HF and the unit has pulse facilities. The powder is supplied from a powder feeder operating on the rotating drum principle. Powder feed rate is controlled by varying the feed opening over the knurled rotating wheel upon which a regulated ribbon of powder is applied, and the powder feed can be regulated to provide an upslope and downslope feed rate. This powder is carried from the container to the work in a stream of argon and is melted in the plasma, the argon providing a shield around the plasma heat zone (Fig. 3.35). Torches are of varying size and cover most

Fig. 3.34. Plasma surfacing.



hard surfacing requirements. As can be seen in the illustration the plasma and powder are supplied through separate passages. Cobalt-based (stellite), nickel-based, iron-based with chrome or molybdenum alloys are available and applications include valve seats, oil drill tool joints, gate valve inserts, diesel engine crossheads, etc. Stellite alloys Nos. 1, 6, 12, 21, 156, 157, 158, F of the stellite range are suitable.

Resistance welding and flash butt welding

Spot welding

In this method of welding use is made of the heating effect which occurs when a current flows through a resistance. Suppose two steel plates A and B (Fig. 4.1) are to be welded together at X. Two copper electrodes are pressed against the plates squeezing them together. The electrical resistance is greatest at the interface where the plates are in contact, and if a large current at low voltage is passed between the electrodes through the plates, heat is evolved at the interface, the heat evolved being equal to I^2Rt joules, where I is the current in amperes, R the resistance in ohms and t the time in seconds. A transformer supplies a.c. at low voltage and high current to the electrodes (Figs. 4.1 and 4.2).

TRANSFORMER
FIXED

For any given joint between two sheets a suitable time is selected and the current varied until a sound weld is obtained. If welds are made near each other some of the current is shunted through the adjacent weld (Fig. 4.3) so that a single weld is not representative of what may occur when several welds are made. Once current and time are set, other welds will be of consistent quality. If the apparatus is controlled by a pedal as in the simplest form of welder, then pressure is applied mechanically and the time for which the current flows is switch controlled, as for example in certain types of welding guns used for car body repairs. This method has the great disadvantage that the time cannot be accurately controlled, so that if it is too short there is insufficient heat and there is no fusion between the plates, whilst if the time is too long there is too much heat generated and the section of the plates between the electrodes melts, the molten metal is spattered out due to the pressure of the electrodes and the result is a hole in the plates. In modern spot-welding machines the pressure can be applied pneumatically or hydraulically or a combination of both and can be accurately controlled. The current is selected by a tapping switch on the primary winding of the transformer and the time is controlled electronically, the making and breaking of the circuit being performed by thyristors.

When the current flows across the interface between the plates, the heating effect causes melting and fusion occurs at *A* (Fig. 4.4). Around this there is a narrow heat-affected zone (HAZ) since there is a quenching effect

Fig. 4.3

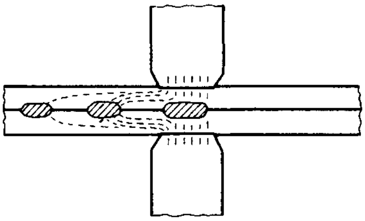

Fig. 4.4

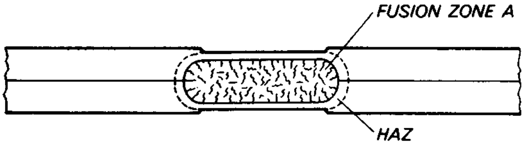


due to the electrodes, which are often water cooled. There are equi-axed crystals in the centre of the nugget and small columnar crystals grow inwards towards the centre of greatest heat.

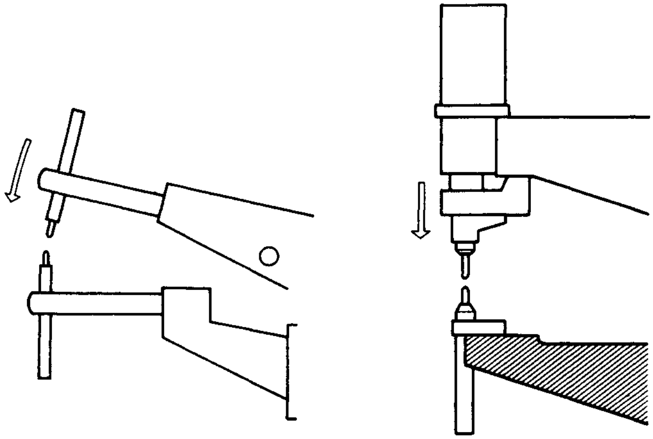
Types of spot welders

In the pedestal type there is a fixed vertical pedestal frame and integral transformer and control cabinet. The bottom arm is fixed to the frame and is stationary during welding and takes the weight of the workpiece. The top arm may be hinged so as to move down in the arc of a circle (Fig. 4.5*a*) or it may be moved down in a straight line (Fig. 4.5*b*). Pivoting arms are adjustable so as to have a large gap between the electrodes, the arms are easily adjusted in the hubs and various length arms are easily fitted giving easy access to difficult joints. The vertical travel machine has arms of great rigidity so that high pressures can be applied, and the electrode tips remain in line irrespective of the length of stroke, so that the machine is easily adapted for projection welding. Additionally the spot can be accurately positioned on the work, and since the moving parts have low inertia, high welding speeds can be achieved without hammering (see Fig. 4.6*a* and *b*).

Welding guns

Portable welding guns are extensively used in mass production. The equipment consists of the welding station often with hydro-pneumatic booster to apply the pressures, a water manifold, one or two welding guns

Fig. 4.5. (*a*) Pivoting arms, (*b*) vertical travel.



(a) PIVOTTING ARMS *(b) VERTICAL TRAVEL*

with balancers, cable between transformer and guns and a control station. In modern machines the composite station with built-in cabinet comprises sequence controls with integrated circuits, thyristor contactors and disconnect switch. Articulated guns (Figs. 4.7*a* and *b*) have both arms articulated as in a pair of scissors, giving a wide aperture between electrodes, and are used for welding joints difficult of access. Small

articulated guns are used for example in car body manufacture for welding small flanges, and in corners and recesses. C guns (Fig. 4.7*c*) have the piston-type ram of the pressure cylinder connected to the moving electrode, which thus moves in a straight line. There is great rigidity and a high working speed because of the low inertia of the moving parts. The electrodes are always parallel and the precision motion is independent of

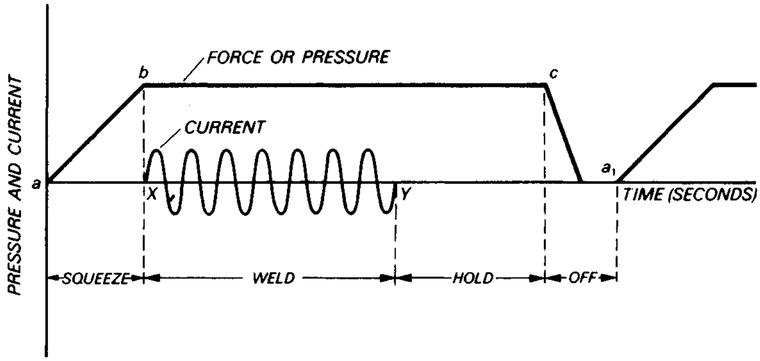
the arm length with easily determined point of welding contact. They are used for quality welds where the height does not preclude them. Integral transformer guns are used to reduce handling costs of bulky fabrications, and the manual air-cooled gun and twin spot gun are used in repair work on car bodies and agricultural equipment and for general maintenance, the latter being used where there is access for only one arm as in closed box sections and car side panels.

The welding cycle

The cycle of operations of most modern machines is completely automatic. Once the hand or foot switch is pressed, the cycle proceeds to completion, the latest form having digital sequence controls with printed circuits, semi-conductors, digital counting and air valve operation by relays. The simplest cycle has one function, namely weld time, the electrode force or pressure being pre-set, and it can be best illustrated by two graphs, one the electrode pressure plotted against time and the other the current plotted against the same time axis (Fig. 4.8). The time axis is divided into 100 parts corresponding to the 50 Hz frequency of the power supply. Fig. 4.8 shows a simple four-event control. First the squeeze is applied and held constant (*a–b* on the graph). The current is switched on at *X*, held for seven complete cycles (7/50 s) and switched off at *Y*. The pressure is held until *c* on the graph, the weld cooling in this period. Finally the squeeze is released and the repeat cycle of operations begins again at a_1. The switches comprise repeat–non-repeat, thyristors on–off and heat control in–out.

For more complex welding cycles, necessary when welding certain metals to give them correct thermal treatment, the graphs are more complex with up to ten functions with variable pressure cycle, and these machines are often operated from three phases. Machines for the aeronautical and space industries are specially designed and incorporate variable pressure heads

Fig. 4.8. Standard four-event sequence for spot welding.



and up to ten functions. Most aluminium alloys lose the properties given to them by work hardening or heat treatment when they are heated. To enable the correct thermal treatment of heating and cooling to be given to them during the welding cycle three-phase machines are often employed.

The transformer

The transformer steps the voltage down from that of the mains to the few volts necessary to send the heavy current through the secondary welding circuit. When the current is flowing the voltage drop across the secondary may be as low as 3–4 volts and in larger machines the current can be up to 35000 A. Because of these large currents there is considerable force acting between the conductors due to the magnetic field, so transformers must be robustly constructed or movement may cause breakdown of the insulation, and in addition they may be water cooled because of the heating effect of the current. The secondary winding consists of one or two turns of copper strip or plates over which the primary coils fit, the whole being mounted on the laminated iron core. Because any infiltration of moisture may lead to breakdown, modern transformers have the primary winding and secondary plates assembled as a unit which is then vacuum encapsulated in a block of epoxy resin. The primary winding has tappings which are taken to a rotary switch which selects the current to be used.

The current flowing in the secondary circuit of the transformer provides the heating effect and depends upon (1) the open circuit voltage and (2) the impedance of the circuit, which depends upon the gap, throat depth and magnetic mass introduced during welding and the resistance of the metal to be welded. The duty cycle is important, as with all welding machines, as it affects the temperature rise of the transformer. For example, if a spot welder is making 48 spot welds per minute, each of 0.25 seconds duration, the duty cycle is $(48 \times 0.25 \times 100) \div 60 = 20\%$. Evidently knowing the duty cycle and welding time, the number of welds that can be made per minute can be calculated.

Electrodes

The electrode arms and tips (Fig. 4.9*a*) which must carry the heavy currents involved and apply the necessary pressure must have the following properties: (1) high electrical conductivity so as to keep the I^2R loss (the heating due to the resistance) to a minimum, (2) high thermal conductivity to dissipate any heat generated, (3) high resistance to deformation under large squeeze pressures, (4) must keep their physical properties at elevated temperatures, (5) must not pick up metal from the surface of the workpiece,

Electrode	Properties	Uses
(1) Copper, 1% silver	High conductivity, medium hardness.	Light alloys, coated sheets, scaly steel.
(2) Copper, 0.6% Cr or 0.5% Cr and Be	Best electrical conductivity with greatest hardness.	Clean or lightly oxidized steel, brass and cupro-nickel. Used for the arms of the machine and electrical conductors.
(3) Copper, 2.5% Co and 0.5% Be	Poor conductivity but very hard.	For welding hard metals with high resistivity, e.g. stainless steel, heat-resistant and special steels.
(4) Copper, beryllium	Poor conductivity, great hardness.	For clamping jaws of flash butt welders.
(5) Molybdenum		Drawn bar or forged buttons used as pressed fit inserts in supports of (2) above. For welding thin sheet or wires or electro-brazing silver-based metals.
(6) Sintered copper-tungsten	Fair conductivity, very hard.	Keeps its mechanical properties when hot.

Note. The addition of various elements increases the hardness but reduces the conductivity.

(6) must be of reasonable cost. The following types of electrodes are chiefly used, and are given in the table. Electrolytic copper (99.95% Cu) has high electrical and thermal conductivity and, when work hardened, resists deformation but at elevated temperatures that part of the electrode tip in contact with the work becomes annealed due to the heating and the tip softens and deforms. Because of this it is usual to water-cool the electrodes to prevent excessive temperature rise.*

Water cooling

Adequate electrode cooling is the most essential factor to ensure optimum tip life; the object is to prevent the electrode material from reaching its softening temperature, at which point it will lose its hardness

Fig. 4.9. (*a*) Electrodes and holders.

and rapidly deteriorate. The normal cooling method is by internal water circulation where the water is fed via a central tube arranged to direct the water against the end of the electrode cooling hole (Fig. 4.9*b*). In some cases a short telescopic extension tube is used inside the main tube and must be adjusted to suit the length of the electrode used.

Electrodes are available with a taper fit to suit the electrode arms and also as tips to fit on to a tapered shank body, which makes them easily interchangeable. The face that makes contact with the metal to be welded can be a truncated cone with central or offset face, flat or domed (Fig. 4.9) and tip diameters can be calculated from formulae which depend upon the plate thickness, but in all cases these are approximate only and do not replace a test on the actual part. Electrodes are subject to great wear and tear in service due to the constant heating and cooling and varying pressure

Fig. 4.9. (*b*)

'EJECTO' ELECTRODE HOLDER

cycles. The chief causes of wear are: electrical; wrong electrode material, poor surface being welded, contacts not in line; mechanical; electrode hammering, high squeeze, weld and forge pressures, abrasion in loading and unloading and tearing due to the parting of the electrodes.

Seam welding

In a seam welding machine the electrodes of a spot welder are replaced by copper alloy rollers or wheels which press on the work to be welded (Fig. 4.10*a* and *b*). Either one or both are driven and thus the work passes between them. Current is taken to the wheels through the rotary bearings by silver contacts with radial pressure and the drive may be by knurled wheel or the more usual shaft drive which enables various types of wheel to be easily fitted. If the current is passed continuously a continuous seam weld results but, as there is a shunt effect causing the current to flow through that part of the weld already completed, overheating may occur resulting in burning of the sheets. To avoid this the current can be pulsed, allowing sufficient displacement of the already welded portion to take place and thus obviating most of the shunt effect. For materials less than 0.8 mm thick or at high welding speeds (6 m/min) no pulsing is required, the 50 Hz frequency of the supply providing a natural pulse. Above 2 × 0.8 mm thickness pulsation is advisable, and essential above 2 × 1.5 mm thickness, while for pressure-tight seams the welds can be arranged to overlap and if the seams are given a small overlap with wide-faced wheels and high pressure a mash weld can be obtained.

By the use of more complex electro-mechanical bearing assemblies, longitudinal and circumferential welds can be made (Fig. 4.10*c*).

Seam welding guns are extremely useful for fabricating all types of tanks, exhaust systems, barrels, drip-mouldings on car body shells, etc. They have electrode drive which automatically propels the gun along the seam so that

it only requires guidance, and they are operated in the same way as spot welding guns.

Direct current spot welding

We have seen that when iron or steel to be welded is placed in a spot or seam welder the impedance of the secondary circuit is increased and the secondary current varies according to the mass introduced. By using d.c. this loss is obviated, the power consumed is reduced and the electrode life increased because skin effect is eliminated. This enables coated steels, stainless and other special steels in addition to aluminium alloys to be welded to high standards. The machine is similar in appearance to the a.c. machine but has silicon diodes as the rectifying elements.

Three-phase machines

Three-phase machines have been developed to give impulse of current in the secondary circuit at low frequency, with modulated wave form to give correct thermal treatment to the material being welded. These machines have greatly increased the field of application of spot welding into light alloys, stainless, and heat-resistant steels, etc. A typical sequence of operations is: squeeze, which multiplies the number of high spots between the contact faces; welding pressure, which diminishes just before the welding current flows; immediately after the passage of the current, forging or recompression pressure is applied which is above the elastic limit of the material and completes the weld. Setting of the welding current can be done by welding test pieces with increasing current until the diameter of the nugget, found by 'peeling' the joint, is $(2t + 3)$, where t is the thickness of the thinner sheet. This current is noted. It is then increased until spatter of the nugget occurs and the welding current is taken as midway between these two values, with final adjustments made on test pieces.

Nickel and nickel alloys have higher electrical resistivity and lower thermal conductivity than steel and are usually welded in thin sections as lap joints, although the crevice between the sheets may act as a stress raiser and affect the corrosion and fatigue resistance. High pressures are required for the high-nickel alloys so as to forge the solidifying nugget, and the machine should have low inertia of the moving parts so that the electrode has rapid follow-up during welding. Current may be set as in the previous section, and in some cases it is advantageous to use an initial squeeze followed by an increasing (up-sloping) current. When the nugget is just beginning to form with diffusion of the interface, the squeeze force is reduced to about one-third of its initial value and held until the current is switched off; this reduces danger of expulsion of molten metal and gives better penetration of the weld into the two sheets.

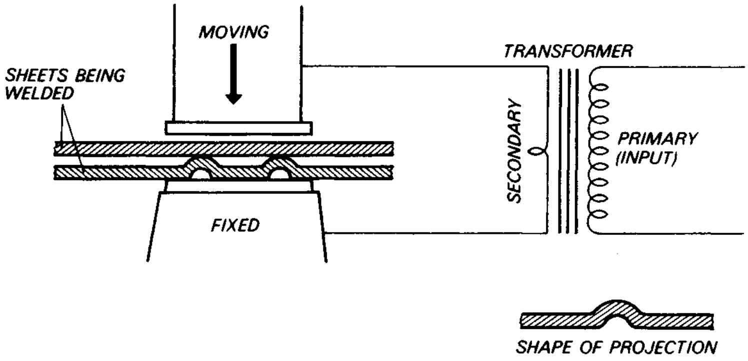
Projection welding

Protrusions are pressed on one of the sheets or strips to be welded and determine the exact location of the weld (Fig. 4.11). Upon passage of the current the projection collapses under the electrode pressure and the sheets are welded together. The machines are basically presses, the tipped electrodes of the spot welder being replaced by flat platens with T slots for the attachment of special tools, and special platens are available which allow the machine to be used as a spot welder by fitting arms and electrodes (Fig. 4.12), and automatic indexing tables can be used to give increased output. Projection welding is carried out for a variety of components such as steel radiator coupling elements, brake shoes, tin-plate tank handles and spouts, etc. The press type of machine is also used for resistance brazing in which the joining of the parts is achieved with the use of an alloy with a lower melting point than the parent metal being welded so that there is no melting involved.

Cross wire welding is a form of projection welding, the point of contact of the two wires being the point of location of the current flow. Low-carbon mild steel, brass, 18/8 stainless steel, copper-coated mild steel and galvanized steel wire can be welded but usually the bulk of the work is done with clean mild steel wire, bright galvanized, or copper coated as used for milk bottle containers, cages, cooker and refrigerator grids, etc., and generally several joints are welded simultaneously.

Modern machines are essentially spot welders in ratings of 25, 70, or 150 kVA fitted with platens upon which suitable fixtures are mounted and having a fully controlled pneumatically operated vertical head, and the electrical capacity to weld as many joints as possible simultaneously. Large programmed machines are manufactured for producing reinforcement mesh automatically.

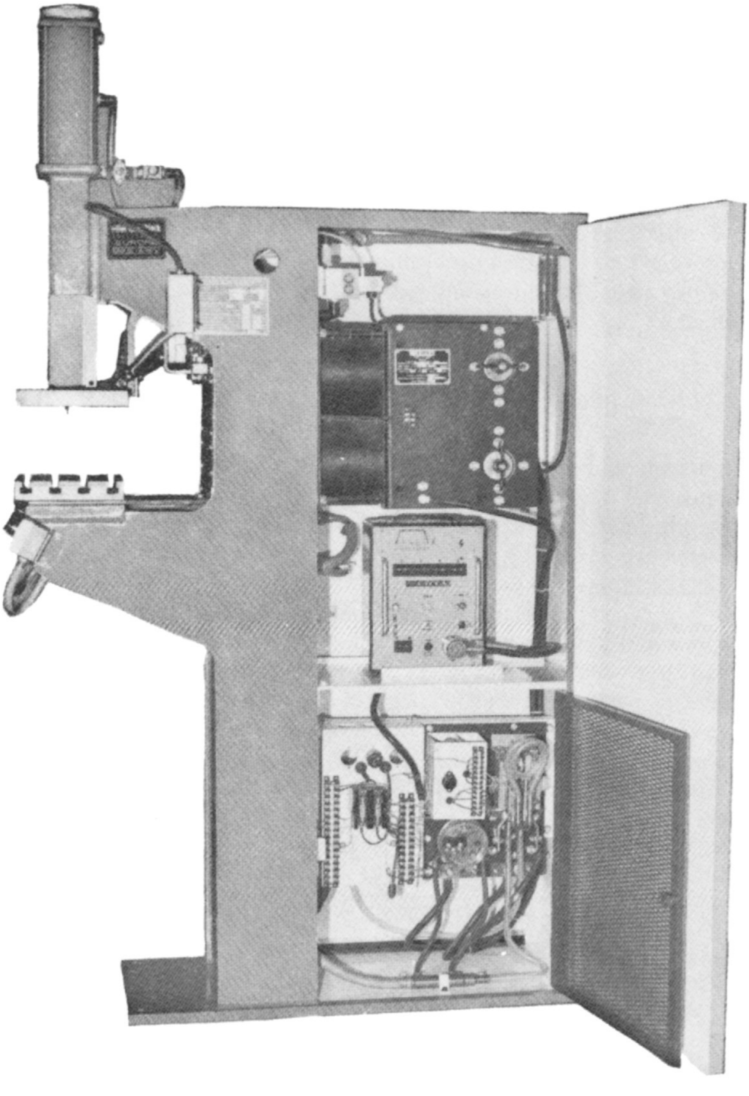
Fig. 4.11. Projection welding.



Resistance butt welding

This method is similar to spot welding except that the parts to be butt welded now take the place of the electrodes. The two ends are prepared so that they butt together with good contact. They are then placed in the jaws of the machine, which presses them close together end to end (Fig. 4.13). When a given pressure has been reached, the heavy current is switched on, and the current flowing through the contact resistance

Fig. 4.12. Projection welder.



between the ends brings them to welding heat. Extra pressure is now applied and the ends are pushed into each other, the white hot metal welding together and an enlargement of section taking place. The section may be machined to size after the operation if necessary.

*Flash butt welding**

Although this is not a resistance welding process it is convenient to consider it here. Flash butt welding machines must be very robustly made and have great rigidity because considerable pressures are exerted and exact alignment of the components is of prime importance. The clamping dies of copper alloy, which carry the current to the components and hold them during butting up under high pressure, should grip over as large an area as possible to reduce distortion tendencies. The clamping pressure, which is about twice the butting pressure, is usually done pneumatically or hydraulically, and current is of the order of 7–10 A/mm^2 of joint area. The following are the stages in the welding cycle.

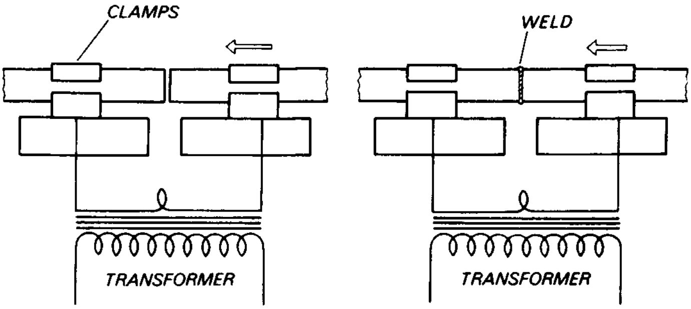
Pre-heat. The components are butted together and a current passing across the joint heats the ends to red heat.

Flash. The parts are separated and an arc is established between them until metal begins to melt, one of the components being moved to keep the arc length constant.

Upset. The parts are butted together under high pressures with the current still flowing. Impurities are forced out of the joint in the butting process and an impact ridge or flash is formed (Fig. 4.14). Post-heat treatment can be given by a variation of current and pressure after welding. For welding light alloys, pre-heating is generally dispensed with and the flashing is of short duration.

As an example of currents involved, a butt weld in 6 mm thick 18/18/3

Fig. 4.13. Resistance butt welding.



---

* BS 499 gives this as a resistance process.

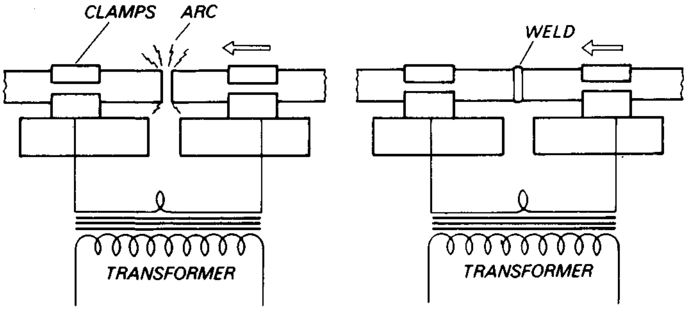
stainless steel with a cross-section of 600 mm^2 involves currents of 20 000 A with a 9 second flashing time.

Flash butt welding is used very extensively by railway systems of the world to weld rails into continuous lengths. British Rail for example weld rails approximately 18.3 m long into continuous lengths from 91 to 366 m and conductor rails are welded in the same way. Fig. 4.15 shows a modern rail welding machine. Hydraulic rams, equally spaced on each side of the rail section, apply the forging load of 200–400 kN to the rails of section approximately 7200 mm^2. The rail is clamped by two vertically acting cylinders and horizontally acting cylinders align each rail to a common datum and an anti-twist device removes axial twist. When welding long lengths of rail it is more convenient to move the machine to the exact position for welding rather than the rail and for this the machine can be rail mounted. Machines of this type can make 150–200 welds per 8-hour shift. In this case the sequence of operations is pre-flash, pre-heat, flashing and forging.

The upset is removed by a purpose-designed machine with hydraulic power-shearing action usually mounted in line with the welding machine.

The flash butt welded lengths are welded *in situ* on the track by the thermit process.

Fig. 4.14. Flash butt welding.



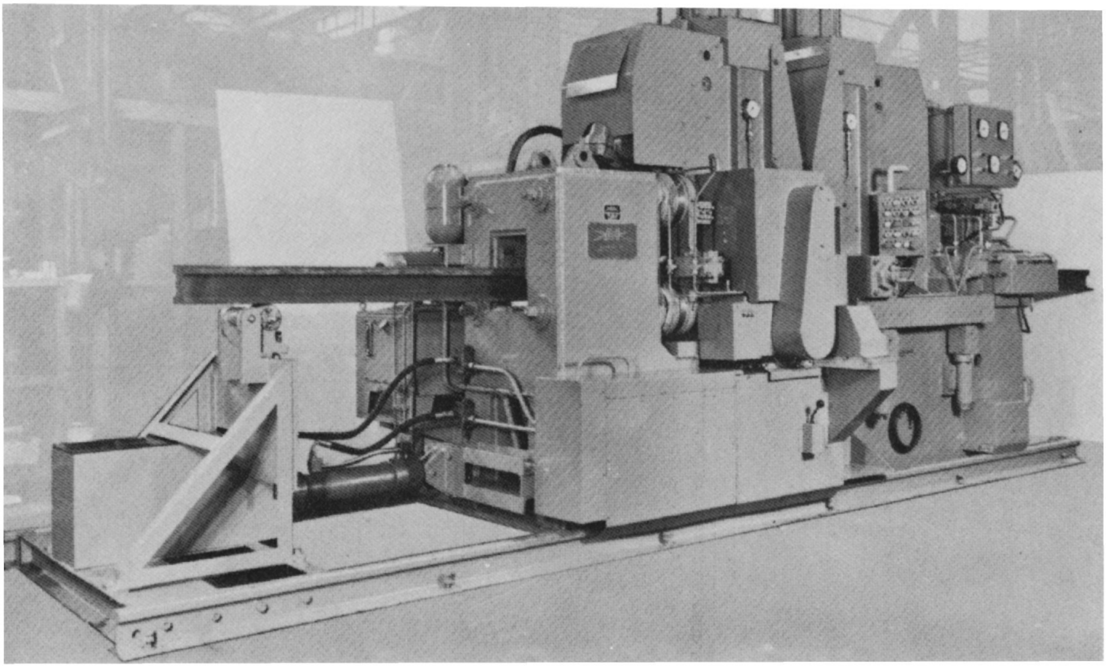


Fig. 4.15. Machine for welding rail sections. 1000 kVA. 3-phase, 440 V. Welding sequence: (1) Both rails securely clamped in welder. (2) Rails aligned vertically and horizontally under full clamping pressure. (3) Weld initiated by push button control. (4) Moving head moves forward on the burn-off or pre-flashing stroke used to square up the ends of the rails if necessary. On completion of this, pre-heating begins until the requisite number of pre-heats have lapsed. At this point the rails should be in a suitably plastic state to allow for straight flashing and finally forging.

5

Additional processes of welding

There has been a great increase in the number of automatic processes designed to speed up welding production. Automatic welding gives high rates of metal deposition because high currents from 400 to 2000 A can be used, compared with the limit of about 600 A with manual arc welding. Automatic arc control gives uniformly good weld quality and finish and the high heat input reduces distortion and the number of runs for a given plate thickness is reduced. Twin welding heads still further reduce welding time, and when used, for example, one on each side of a plate being fillet welded, distortion is reduced. The welding head may be:

1. Fixed, with the work arranged to move beneath it.
2. Mounted on a boom and column which can either be of the positioning type in which the work moves or the boom can traverse at welding speed over the fixed work.
3. Gantry mounted so that it can traverse over the stationary work.
4. Self propelled on a motor-driven carriage.

The processes which have been described previously in this book, namely TIG, MIG and CO_2 (gas shielded metal arc) with their modifications, are extensively used fully automatically. Heads are now available which, by changing simple components, enable one item of equipment to be used for MIG (inert gas), CO_2 and tubular wire, and submerged arc processes.

Submerged arc welding (sub-arc)*

In this automatic process the arc is struck between bare or flux cored wire and the parent plate, the arc, electrode end and the molten pool are submerged or enveloped in an agglomerated or fused powder which turns into a slag in its lower layers under the heat of the arc and protects the weld from contamination. The wire electrode is fed continuously to the arc by a feed unit of motor-driven rollers which is voltage-controlled in the same way as the wire feed in other automatic processes and ensures an arc of constant length. The flux is fed from a hopper fixed to the welding head, and a tube from the hopper spreads the flux in a continuous mound in front of the arc along the line of weld and of sufficient depth to completely submerge the arc, so that there is no spatter, the weld is shielded from the atmosphere and there are no radiation effects (UV and IR) in the vicinity. (Fig. 5.1*a* and *b*.) A latest development to increase deposition rate is to lay down a powder in front of flux feed and welding head; this is generally used with a tandem a.c./d.c. head.

---

* American designation SAW (similar to British).

Welding heads

Fully automated welding heads for this process can also be used with modification for gas shielded metal arc welding including CO_2, solid and flux cored, thus greatly increasing the usefulness of the equipment. The head can be stationary and the work moved below it, as for example in the welding of circumferential and longitudinal seams, or the head may be used with positioners or booms or incorporated into custom-built mass production welding units for fabricating such components as brake shoes, axle housings, refrigerator compressor housings, brake vacuum cylinders, etc., and hard surfacing can also be carried out. The unit can also be tractor mounted (cf. Fig. 5.2*c*) and is self-propelled, with a range of speeds of 100 mm to 2.25 m per minute, and arranged to run on guide bars or rails. Oscillating heads can be used for root runs on butt joints to maintain a

ARC AND MOLTEN POOL HIDDEN UNDER LAYER OF FLUX

constant welding bead on the underside of the joint, and two and even three heads can be mounted together or the heads can be arranged side by side to give a wide deposit as in hard surfacing. Fillet welding can be performed by inclining two heads, one on each side of the joint, with flux feeds and recovery, the heads being mounted on a carriage which travels along a gantry over the work (Fig. 5.2). Two heads mounted in tandem and travelling either along a guide rail or directly on the workpiece are used for butt joints on thick plate, and both can operate on d.c. or the leading head can operate on d.c. and the trailing head on a.c.

Three electrode heads can be gantry mounted on a carriage, the leading electrode being d.c. operated with the trailing electrodes a.c. This method gives high deposition rates with deep penetration. Special guide units ensure in all cases that the electrode is correctly positioned relative to the joint.

The main components in the control box are: welding voltage and arc

Fig. 5.1. (*b*)

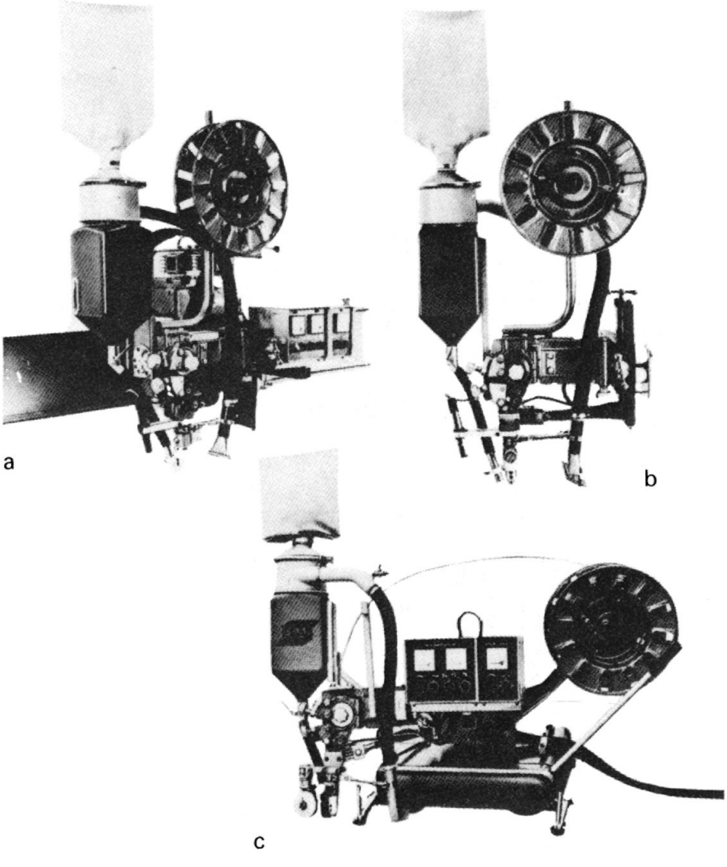
current controls, and wire feed controlled by a thyristor regulator which maintains set values of arc voltage. The head is accurately positioned by slide adjusters for horizontal and vertical movement and has angular adjustment also. The wire feed motor has an integral gearbox and wire-straightening rolls give smooth wire feed. The gear ratio for the metal arc process is much higher than for submerged arc and each wire diameter usually requires its own feed rolls, which are easily interchanged. For fine wires less than 3 mm diameter a fine-wire-straightening unit can be fitted.

Current is passed to the electrode wire through a contact tube and jaws

Fig. 5.2. Various mountings for automatic welding equipment.
(*a*) An automatic welding machine in which the head is mounted on a carriage which travels along a beam.
(*b*) An automatic welding head as in (*a*) designed for stationary mounting on a manipulator column or boom in order to be an integral part of a mechanized welding system.
(*c*) A tractor-mounted automatic welding head as in (*a*). The machine has a single welding head and is designed for welding butt joints and for making fillet welds in the flat or horizontal–vertical position.



which fit the wire diameter being used, and the contact tube is used for the shielding gas when gas shielded welding is being performed and is water cooled. The coil arm holder has a brake hub with adjustable braking effect and carries 300 mm i.d. coils, and a flux hopper is connected to a flux funnel attached to the contact tube by a flexible hose.

A guide lamp which is attached to the contact tube provides a spot of light which indicates the position of the wire, thus enabling accurate positioning of the head along the joint, and a flux recovery unit collects unfused flux and returns it to the hopper.

A typical sequence of operations for a boom-mounted carriage carrying multiple welding head is: power on, carriage positioned, welding heads 1, 2, etc., down, electrode feed on, wire tips set, flux valve open, welding speed set, welding current set, welding voltage set, flux recovery on; press switch to commence welding.

Power unit

The power unit can be a motor- or engine-driven d.c. generator or transformer-rectifier with outputs in the 30–55 V range and with currents from 200 to 1600 A with the wire generally positive. In the case of multiple head units in which the leading electrode is d.c. and the trailing electrode is a.c. a transformer is also required. In general any power source designed for automatic welding is usually suitable when feeding a single head.

Wires are available in diameters of 1.6, 2.0, 2.4, 3.2, 4.0, 5.0, 6.0 mm on plastic reels or steel formers. Wrappings should be kept on the wire until ready for use and the reel should not be exposed to damp or dirty conditions.

A variety of wires are available including the following (they are usually copper coated). For mild steel types with varying manganese content, e.g. 0.5%, 1.0%, 1.5%, 2.0% manganese, a typical analysis being 0.1% C, 1.0% Mn, 0.25% Si, with S and P below 0.03%. For low alloy steels, 1,25% Cr, 0.5% Mo; 2.25% Cr, 1.0% Mo; 0.2% Mn, 0.5% Mo; and 1.5% Mn 0.5% Mo are examples, whilst for the stainless steel range there are: 20% Cr, 10% Ni for unstabilized steels; 20% Cr, 10% Ni, 0.03% C, for low-carbon 18/8 steels; 19% Cr, 12% Ni, 3% Mo for similar steels; 20% Cr, 10% Ni, nobium stabilized; 24% Cr, 13% Ni for steels of similar composition and for welding mild and low-alloy steels to stainless steel.

Many factors affect the quality of the deposited weld metal: electrode wire, slag basicity, welding variables (process), cleanliness, cooling rate, etc. For hardfacing, the alloy additions necessary to give the hard surface usually come from the welding wire and a neutral flux, and tubular wire with internal flux core is also used in conjunction with the external flux.

Hardness values as welded, using three layers on a mild steel base, are between 230 and 650 HV depending upon the wire and flux chosen.

Flux (see also Vol. 1, pp. 61–3)

Fluxes are suitable for use with d.c. or a.c. They are graded according to their form, whether (1) fused or (2) agglomerated. Fused fluxes have solid glassy particles, low tendency to form dust, good recycling properties, good slag-flux compatibility, low combined water and little sensitivity to humid conditions. Agglomerated fluxes have irregular-sized grains with low bulk density, low weight consumption at high energy inputs with active deoxidizers and added alloying elements where required.

Fluxes are further classified as to whether they are acidic or basic, the basicity being the ratio of basic oxides to acidic oxides which they contain. In general the higher the basicity the greater the absorption of moisture and the more difficult it is to remove.*

The general types of flux include manganese silicate, calcium manganese aluminium sulphate, rutile, zirconia and bauxite, and the choice of flux affects the mechanical properties of the weld metal. Manufacturers supply full details of the chemical composition and mechanical properties of the deposited metal when using wires of varying compositions with various selected fluxes (i.e. UTS, % elongation Charpy impact value, and CTOD† figures at various temperatures).

Fluxes that have absorbed moisture should be dried in accordance with the makers' instructions, as the presence of moisture will affect the mechanical properties of the deposited metal. The flux, whether fused or agglomerated, should be chosen to give the weld as near as possible the same characteristics as the parent plate. Wire composition and chosen flux must be compatible. Tensile and yield strength, together with impact values of the welded joint must all be considered.

The strength of carbon–manganese steels depends upon the carbon, silicon and manganese content. Of these, the manganese content can most easily be varied by additions to the flux to obtain the various levels of strength. In general, the manganese content of the weld metal should be equal to or exceed that of the parent plate. Too much manganese will result in brittleness. The impact value is governed by the basicity of the flux; an increase of basicity results in a decrease of arc stability, a reduction in weld appearance and more difficult slag removal. In general the flux of highest basicity consistent with stable arc, good weld appearance and easy slag removal should be chosen.

---

* Basicity (BI) $= \dfrac{\mathrm{CaO+CaF_2+MgO+K_2O+Na_2O+\frac{1}{2}(MnO+FeO)}}{\mathrm{SiO_2+\frac{1}{2}(Al_2O_3+TiO_2+ZrO_2)}}$. The basicity may vary from 0.7 to 3.1 (see also Vol. 1, pp. 61–4.

† Crack tip opening displacement Vol. 1, pp. 284–9.

Electrode wires, wound on reels, are available, together with compatible fluxes for carbon–manganese steels, low-alloy steels and stainless steels. For duplex stainless steels use a flux such as OK 16.93 or 18.86, and for super duplex use flux OK 16.88. See table, p. 181, for filler wire and fluxes.

Joint preparation

Joint edges should be carefully prepared and free from scale, paint, rust and oil, etc., and butt seams should fit tightly together. If the fit-up has gaps greater than 0.8 mm these should be sealed with a fast manual weld.

When welding curved circumferential seams there is a tendency for the molten metal and slag, which is very fluid, to run off the seam. This can be avoided or reduced by having the welding point 15–65 mm before top dead centre in the opposite direction to the rotation of the work and in some cases the speed of welding and current can be reduced. Preparation of joints is dependent upon the service to which the joint is to be put and the following preparations are given as examples only (Fig. 5.3).

Backing

As the cost of back-chipping and making a sealing run has escalated it becomes more and more necessary to be able to weld plates and cylinders of large size with a run on one side only. This may be the case, for example, if the fit-up of the sections is poor and a weld in the root of the section may not be able to bridge a wide root gap successfully. In these cases a backing can be used so that the weld is performed from one side only and with which a good profile of underbead is obtained even when fit-up and alignment are not good. The following are examples of differing types of backing strips available.

Ceramic tile backing strip. This is shown in section in Fig. 5.4*a* and is suitable for slag-forming processes such as submerged arc, or flux cored and MMA can be used for vertical and horizontal–vertical butts. A recess in the tile allows the slag to form below the underbead and is stripped off and discarded with the aluminium foil which holds it in position as the weld progresses.

Fibreglass tape backing strip is a closely woven flexible material of about four to six layers and fibreglass tape which gives good support to the underbead or root run of the weld and is usually used in conjunction with a copper or aluminium backing bar. It is non-hygroscopic and has low fume level. Sizes are from 30 mm wide heavy single layer, 35 mm wide four layer and 65 mm wide six layer.

Fibreglass tape, sintered sand backing plate. This is typical for submerged arc single or twin wire as in large structures, e.g. deck plates in shipyards, etc. The backing is of sintered sand (silica) about 600 mm long, 50 mm wide and 10 mm thick reinforced with steel wires. It has a fibreglass tape fitted to the upper surface to support the root of the weld and has adhesive outer edges to allow for attachment to the joint, which should be dry and which should have a 40–50° included angle preparation and a root gap of about 4 mm. The backing is slightly flexible to allow for errors of alignment and has 45° bevelled ends. Overlapping tape prevents burn-through at the

Electroslag welding (Fig. 5.5)

Developed in Russia, this process is used for butt welding steel sections usually above 60 mm in thickness although plates down to 10 mm thick can be welded. The sections to be welded are fixed in the vertical position and part of the joint line, where welding is to commence, is enclosed with water-cooled copper plates or dams which serve to position the molten weld metal and slag. The dams are pressed tightly against each side of the joint to prevent leakage. There may be from one to three electrode wires depending upon the thickness of the section and they are fed continuously from spools. The self-adjusting arc is struck on to a run-off plate beneath a coating of powder flux which is converted into a liquid in about half a minute. The current is then transferred, not as an arc but through the liquid slag, which gives the same order of voltage drop as would the arc. During welding some slag is lost in forming a skin between the molten metal and the copper dams, and a flow of powder, carefully metered to avoid disturbing the welding conditions, is fed in to make good wastage. The vertical traverse may be obtained by mounting the welding

head on a carriage which is motor-driven and travels up a rack on a vertical column in alignment with the joint to be welded. The rate of travel is controlled so that the electrode nozzle and copper dams are in the correct position with regard to the molten pool, and since the electrode is at right angles to the pool, variations in fit-up are not troublesome. For thick sections the electrodes are given a weaving motion across the metal.

The welds produced are free from slag inclusions, porosity and cracks, and the process is rapid, preparation is reduced, and there is no deslagging. Composite wires containing deoxidizers and alloying elements can be used when required. A variation of the process uses a CO_2 shield instead of the flux powder, the CO_2 being introduced through pipes in the copper dams just above the molten metal level.

Electroslag welding with consumable guides or nozzles

Consumable guide welding is a development of the electroslag process for welding straight joints in thick plate in the vertical or near vertical position, in a range of 15–40 mm thick plate and with joints up to 2 m long. The set-up gap between plates is 25–30 mm, but when welding

COPPER SHOE OR DAM
SOLIDIFIED WELD METAL

thicknesses less than 20 mm the joints can be reduced to 18–24 mm, the gap ensuring that the guide tube does not touch the plate edges. Water-cooled copper shoes act as dams and position the molten metal and also give it the required weld profile. As with electroslag welding the current passing through the molten slag generates enough heat to melt the electrode end, guide and edges of the joint, ensuring a good fusion weld. If a plain uncoated guide tube is used, flux is added to cover the electrode and guide end before welding commences. To start the process the arc is struck on the work. It continues burning under the slag with no visible arc or spatter. The slag should be viewed through dark glasses as in gas cutting because of its brightness when molten.

An a.c. or d.c. power source in the range 300–750 A is suitable, such as is used for automatic and MMA processes. Striking voltage is of the order of 70–80 V, with arc voltages of 30–50 V, higher with a.c. than d.c.

The advantages claimed for the process are: relatively simpler, cheaper, and more adaptable than other similar types, faster welding than MMA of thick plate, cheaper joint preparation, even heat input into the joint thus reducing distortion problems, no spatter losses, freedom from weld metal defects and low consumption of flux. Fig. 5.6 illustrates the layout of the machine.

Mechanized MIG welding with robots (robotics)

Fully automatic welding using the gas shielded metal arc or submerged arc processes in conjunction with columns and booms, positioners, rotators and other equipment such as jigs is extensively used for the making of welds either straight, circumferential or circular. The use of robots in the car industry for spot welding the body shell, spray painting and general assembly is well known and it has resulted in increased speed of production and less overall cost with reduced monotony and fatigue for the operator.

Now consider the robot adapted to the fabrication of large numbers of similar components with welds in all positions performed by the gas shielded metal arc process.

The word robot comes from the Czech word *robota* which, in translation, means any class of work that involves monotony, repetition or drudgery. When operating the robot the welder becomes the supervisor for whom the robot works, performing this monotonous work at speed, with accuracy and not getting tired or needing breaks.

To serve as an example we can consider one particular modern robot illustrated in Fig. 5.7.

This has six degrees of freedom, (one being optional) based on the human hand, wrist and forearm and the following gives the approximate movement values:

> rotational 340°, radial arm 550 mm max., vertical arm 850 mm max., wrist bending 90°, wrist turning 180°.

The accuracy of these movements is 0.1–0.2 mm at 500 mm distance and it should be noticed that the robot can be equipped with heads for selection, grinding, polishing and spot welding, if required.

Evidently there must be large production runs of components with repetitive welding to be performed for the cost of the station, consisting of positioners, control cabinets, robot with gas shielded metal arc welding,

head and power and control unit, to be justified. Once the decision has been taken for the outlay to be justified the advantages that accrue are great.

The production station, which varies according to the size of the work pieces, can consist, for example, of two positioners, on which the work is jig held. These positioners (Fig. 5.8) and the data required in the welding operations are controlled by a microcomputer and are servo-steered.

The robot head has a gas shielded metal arc welding gun adapted to fit the head, the power source is of the thyristor-controlled constant voltage type and the wire is fed from a unit which controls speed of feed and compensates for variations of mains voltage and friction of the feed rollers.

To program the robot, the programming unit is taken from the control cabinet and the robot run through the complete welding sequence for the part to be fabricated. The welding gun is moved from point to point and each section is fed with the speed required and the welding parameters (current and voltage, etc.), and the accelerated movement from one welding point to the next is also programmed and mistakes are easily corrected. The computer memory has say 500 position capacity with additional instructions with a tape recorder increasing the memory. The storage of the program is on a digital tape cassette so that the switch from one program to another can be made without starting from scratch. As is usual pre- and post-flow of the shielding gases and crater filling are all part of the program. (*Note.* The TIG method of welding may also be performed by robots. See Chapter 3.)

Pressure welding

This is the joining together of metals in the plastic condition (not fusion) by the application of heat and pressure as typified by the blacksmith's weld. In general the process is confined to butt welding. The parts (tubes are a typical example) are placed on a jig which can apply pressure to force the parts together.

The faces to be welded are heated by oxy-acetylene flames, and when the temperature is high enough for easy plastic flow to take place, heating ceases and the tubes are pushed together causing an upset at the welded face. The welding temperature is about 1200 °C for steel. It is considered that atoms diffuse across the interfaces and recrystallization takes place, the grains growing from one side to the other of the welded faces since they are in close contact due to the applied pressure. Any oxide is completely broken up at a temperature well below that of fusion welding but due to the heating time concerned, grain growth is often considerable. Steel, some alloy steels, copper, brass, and silver can be welded by this process.

Cold pressure welding

Cold pressure welding is a method of joining sections of metal together by the application of pressure alone using no heat or flux. Pressure

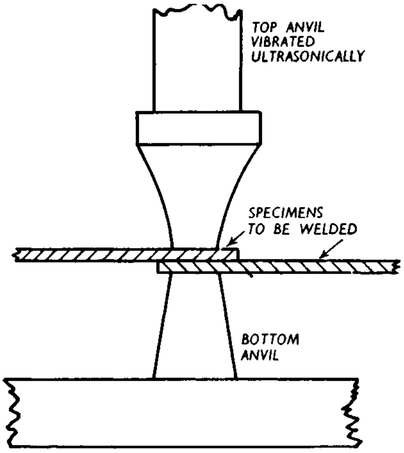
is applied to the points to be welded at temperatures below the recrystallization temperature of the metals involved. This applied pressure brings the atoms on the interface to be welded into such close contact that they diffuse across the interface and a cold pressure weld is made.

It is a method for relatively ductile metals such as aluminium, copper cupro-nickel, gold, silver, platinum, lead, tin and lead–tin alloys, etc., and it is particularly suited to welds in circular wire section. In the type described of the multiple upset type, the surfaces to be welded are placed in contact and held in position by gripping dies and are fed together in small increments by a lever (Fig. 5.9). Each lever movement giving interface pressure displaces the original surfaces by plastic flow and after about four to six upsets, the last movement completes the weld and the flash is easily removed. In the machine illustrated, copper wire 1.1–3.5 mm diameter max. or aluminium wire to 4.75 max. can be butt welded. Fig. 5.10*a* and *b* illustrates the micrographs of welds made in copper to copper and copper to aluminium wire.

Ultrasonic welding

Ultrasonic vibrations of several megacycles per second (the limit of audibility is 20 000–30 000 Hz) are applied to the region of the faces to be welded. These vibrations help to break up the grease and oxide film and heat the interface region. Deformation then occurs with the result that welding is possible with very greatly reduced pressure compared with an ordinary pressure weld. Very thin section and dissimilar metals can be welded and because of the reduced pressure there is reduced deformation (Fig. 5.11).

Fig. 5.11. Ultrasonic welding.



Friction welding

The principle of operation of this process is the changing of mechanical energy into heat energy. One component is gripped and rotated about its axis while the other component to be welded to it is gripped and does not rotate but can be moved axially to make contact with the rotating component. When contact is made between rotating and non-rotating parts heat is developed at the contact faces due to friction and the applied pressure ensures that the temperature rises to that required for welding. Rotation is then stopped and forging pressure applied, causing more extrusion at the joint area, forcing out surface oxides and impurities in the form of a flash (Fig. 5.12). The heat is concentrated and localized at the interface, grain structure is refined by hot work and there is little diffusion across the interface so that welding of dissimilar metals is possible.

In general at least one component must be circular in shape, the ideal situation being equal diameter tubes, and equal heating must take place over the whole contact area. If there is an angular relationship between the final parts the process is not yet suitable.

The parameters involved are: (1) the power required, (2) the peripheral speed of the rotating component, (3) the pressure applied and (4) the time of duration of the operation. By adjusting (1), (2) and (3), the time can be reduced to the lowest possible value consistent with a good weld.

Power required. When the interfaces are first brought into contact, maximum power is required, breaking up the surface film. The power required then falls and remains nearly constant while the joint is raised to welding temperature. The power required for a given machine can be chosen so that the peak power falls within the overload capacity of the driving motor. It is the contact areas which determine the capacity of a machine. The rotational speed can be as low as 1 metre per second peripheral and the pressure depends upon the materials being welded, for example for mild steel it can be of the order of 50 N/mm^2 for the first part of the cycle followed by 140 N/mm^2 for the forging operation. Non-ferrous metals require a somewhat greater difference between the two operations. The faster the rotation of the component and the greater the pressure, the shorter the weld cycle, but some materials suffer from hot cracking if the cycle is too short and the time is increased with lower pressure to increase the width of the HAZ. At the present time most steels can be welded including stainless, but excluding free cutting. Non-ferrous metals are also weldable and aluminium (99.7% Al) can be welded to steel.

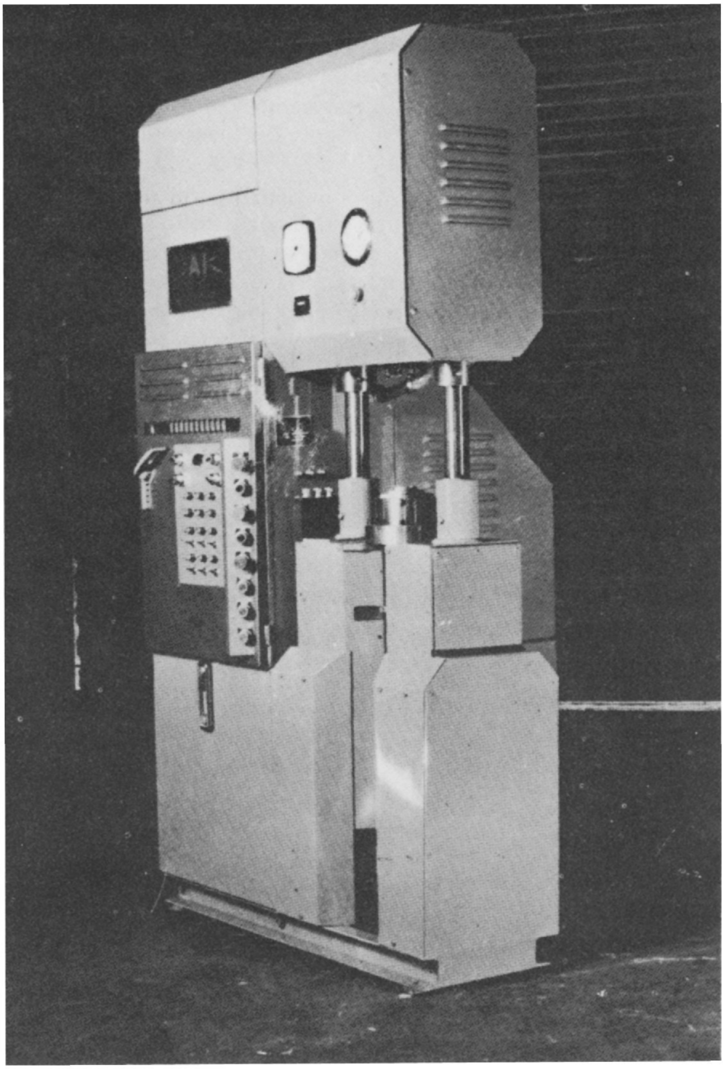
Fig. 5.13. Friction welder.



There are various control systems: (1) Time control, in which after a given set time period after contact of the faces, rotation is stopped and forge pressure is applied. There is no control of length with this method. (2) Burn-off to length: parts contact and heating and forging take place within a given pre-determined length through which the axially moving component moves. (3) Burn-off control: a pre-determined shortening of the component is measured off by the control system when minimum pressures are reached. Weld quality and amount of extrusion are thus controlled, but not the length. (4) Forging to length: the axially moving work holder moves up to a stop during the forging operation irrespective of the state of the weld and generally in this case extrusion tends to be excessive.

The extrusion of flash can be removed by a subsequent operation or, for example for tubes of equal diameter, a shearing unit can be built into the machine operating immediately after forging and while the component is hot, thus requiring much less power. Fig. 5.12(*a*) illustrates a joint designed to contain the flash.

In the process known as inertia welding the rotating component is held in a fixture attached to a flywheel which is accelerated to a given speed and then uncoupled from its drive. The parts are brought together under high thrust and the advantage claimed is that there is no possibility of the driving unit stalling before the flywheel energy is dissipated.

Friction welding machines resemble machine tools in appearance, as illustrated in Fig. 5.13.

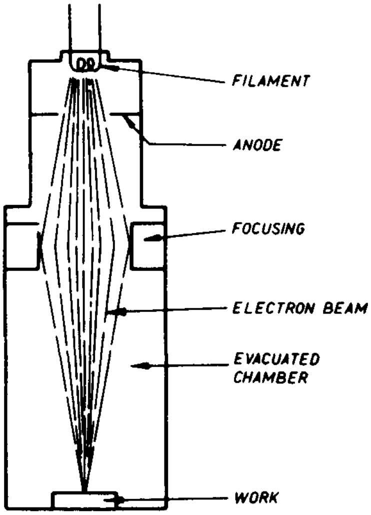
Electron beam welding

If a filament of tungsten or tantalum is heated to high temperature in a vacuum either directly by means of an electric current or indirectly by means of an adjacent heater, a great number of electrons are given off from the filament, which slowly evaporates. This emission has been mentioned previously in the study of the tungsten arc welding process. The greater the filament current the higher the temperature and the greater the electron emission, and if a metal disc with a central hole is placed near the filament and charged to a high positive potential relative to the filament, so that the filament is the cathode and the disc the anode, the emitted electrons are attracted to the disc and because of their kinetic energy pass through the hole as a divergent beam. This can then be focused electrostatically, or magnetically, by means of coils situated adjacent to the beam and through which a current is passed. The beam is now convergent and can be spot focused. The basic arrangement, an electron 'gun', is similar to that used for television tubes and electron microscopes (Fig. 5.14).

If the beam is focused on to a metal surface the beam can have sufficient energy to raise the temperature to melting point, the heating effect depending upon the kinetic energy of the electrons. The kinetic energy of an electron is $\frac{1}{2}mV^2$, where m is the mass of an electron (9.1×10^{-28} g) and V its velocity. The electron mass is small, but increasing the emission from the filament by raising the filament current increases the number of electrons and hence the mass effect. Because the kinetic energy varies directly as the square of the velocity, accelerating the electrons up to velocities comparable with the velocity of light by using anode voltages (up to 200 kV) greatly increases the beam energy. The smaller the spot into which the beam is focused the greater the energy density but final spot size is often decided by working conditions, by aberration in the focusing system, etc., so that spot size may be of the order of 0.25–2.5 mm.

When the beam strikes a metal surface X-rays are generated, so that adequate precautions must be taken for screening personnel from the rays by using lead or other metal screens or making the metal walls of the gun chamber sufficiently thick. If the beam emerges into the atmosphere the energy is reduced by collision of the electrons with atmospheric molecules and focus is impaired. Because of this it has been the practice to perform many welding operations in a vacuum, either in the gun chamber in which case each time the component is loaded the chamber must be evacuated to high vacuum conditions, thus increasing the time and cost of the operation, or in a separate steel component chamber fixed to the gun chamber. This can be made of a size to suit the component being welded and is evacuated

Fig. 5.14. Electron beam welding.



to a relatively low vacuum after each loading. In either case welds suffer no contamination because of vacuum conditions. Viewing of the spot for set-up, focusing and welding is done by various optical arrangements.

Welding in non-vacuum conditions requires much greater power than for the preceding method because of the effects of the atmosphere on the beam and the greater distance from gun to work, and a shielding gas may be required around the weld area. Research work is proceeding in this field involving guns of higher power consumption. Difficulties may also be encountered in focusing the beam if there is a variation in the gun-to-work distance, as on a weld on a component of irregular shape.

Welds made with this process on thicker sections are narrow with deep penetration with minimum thermal disturbance and at present welds are performed in titanium, niobium, tungsten, tantalum, beryllium, nickel alloys (e.g. nimonic), inconel, aluminium alloys and magnesium, mostly in the aero and space research industries. The advantages of the process are that being performed in a vacuum there is no atmospheric contamination and the electrons do not affect the weld properties, accurate control over welding conditions is possible by control of electron emission and beam focus, and there is low thermal disturbance in areas adjacent to the weld (Fig. 5.15). Because of the vacuum conditions it is possible to weld the more reactive metals successfully. On the other hand the equipment is very costly, production of vacuum conditions is necessary in many cases and there must be protection against radiation hazards.

Laser beam welding*

Radio waves, visible light, ultra-violet and infra-red radiations are electro-magnetic radiations which have two component fields, one electric and the other magnetic, vibrating at right angles to each other and to the direction of propagation of the beam. If either one of these components is suppressed the resulting radiations are said to be polarized and the direction in which the resultant electric or magnetic forces act is the plane of polarization. Light from a source such as a tungsten filament electric light consists of several frequencies involving various shades of colour. These waves are not in phase and are of various amplitudes and planes of polarization, and the light is said to be non-coherent. Light of a single wave-length or frequency is termed monochromatic. The wave-length of light is measured in metres or micro-metres, termed microns (μm), visible light being in the range 0.4–0.7 μm. The frequency is related to the wave-length by the expression $V = n\lambda$, where n is the frequency in Hz, λ the wave-length in metres and V the velocity of electro-magnetic radiation,

---

* The velocity of light is 3×10^{10} cm/s (~ 186000 mps).

3×10^8 m/s, so that the frequency range of visible light is in the range $430–750 \times 10^{12}$ Hz.

Atoms of matter can absorb and give out energy and the energy of any atomic system is thereby raised or lowered about a mean or 'ground' level. When an atom or molecule is at an energy level higher than that of the ground state (or level) it is said to be excited, and in this condition two similar atoms can combine to form a molecule called a 'dimer'. The combination is for an extremely short time, and only when in the excited state. Energy can only be absorbed by atoms in definite small amounts (quanta) termed photons, and the relationship between the energy level and the frequency of the photon is $E = h\nu$, where E is the energy level, h is Planck's constant and ν the photon frequency, so that the energy level depends upon the frequency of the photon. An atom can return to a lower energy level by emitting a photon and this takes place in an exceedingly short space of time from when the photon was absorbed, so that if a photon of the correct frequency strikes an atom at a higher energy level, the photon which is released is the same in phase and direction as the incident photon.

The principle of the laser (Light Amplification by Stimulated Emission of Radiation) is the use of this stimulated energy to produce a beam of

Fig. 5.15. Electron beam welding machine with indexing table, tooled for welding distributor shafts to plates at a production rate of 450 per hour. The gun is fitted with optical viewing system. Power 7.5 kW at 60 kV, 125 mA. Vacuum sealing is achieved by seals fitted in the tooling support plate and at the bottom of the work chamber. As the six individual tooling stations reach the welding station they are elevated to the weld position and then rotated by an electronically controlled d.c. motor.

OPERATOR INITIATION

coherent light, that is one which is monochromatic, and the radiation has the same plane of polarization and is in phase. Lasers operate with wavelengths in the visible and infra-red region of the spectrum. When the beam is focused into a small spot and there is sufficient energy, welding, cutting and piercing operations can be performed on metals.

The ruby laser has a cylindrical rod of ruby crystal (Al_2O_3) in which there is a trace of chromium as an impurity. An electronic flash gun, usually containing neon, is used to provide the radiation for stimulation of the atoms. This type of gun can emit intense flashes of light of one or two milliseconds duration and the gun is placed so that the radiations impinge on the crystal. The chromium atoms are stimulated to higher energy levels, returning to lower levels with the emission of photons. The stimulation continues until an 'inversion' point is reached when there are more chromium atoms at the higher levels than at the lower levels, and photons impinging on atoms at the higher energy level cause them to emit photons. The effect builds up until large numbers of photons are travelling along the axis of the crystal, being reflected by the ends of the crystal back along the axis, until they reach an intensity when a coherent pulse of light, the laser beam (of wave-length about 0.06 μm), emerges from the semi-transparent rod end. The emergent pulses may have high energy for a short time period, in which case vaporization may occur when the beam falls on a metal surface, or the beam may have lower energy for a longer time period, in which case melting may occur, while a beam of intermediate power and duration may produce intermediate conditions of melting and vaporization, so that control of the time and energy of the beam and focusing of the spot exercise control over the working conditions.

Developments of the ruby laser include the use of calcium tungstate and glass as the 'host' material with chromium, neodymium, etc., as impurities, a particular example being yttrium–aluminium–garnet with neodymium (YAG), used for operations on small components.

The CO_2 laser uses carbon dioxide for its main gas, with a little helium or nitrogen. The tube may be some metres long, the average length of the beam (10.6 μm) being longer than that of the solid state laser and other continuous wave or pulsed (the power increasing with the length of the tube). To increase the power without increasing the length of the unit, folded-beam lasers have many shorter tubes set parallel to each other; the beam passes down each tube and is reflected from specially ground polished copper mirrors set at the end of each tube. As with other gas lasers, electrical stimulation is by means of an HF discharge from a tube (similar to a fluorescent tube).

A solid state laser (ruby, Nd–YAG), with operational wave-length of 1.06 μm in the infra-red wave band, uses the heating effect of the beam.

Gas lasers use argon fluoride, krypton fluoride and xenon fluoride (and chlorides), giving a pulsed beam of 25–50 W at the ultra-violet end of the spectrum with little or no heat. On starting the tube, electrical stimulation from a radio frequency (r.f.) generator is connected to each end of the tube. The helium atoms, or those of other seeding gases, are stimulated and their energy level raised above ground level. These atoms transfer their energy to the other gas in the tube, until inversion occurs and a coherent beam is emitted. This is known as collision excitation and gas lasers are used for visual effects of various colours.

The excimer laser is of the helium–neon type and stimulation of the gas is to an energy level such that two atoms combine to form a 'dimer'. Energy is obtained from an HF electrical discharge through the tube. When the laser beam strikes a surface it dissociates the bond between the molecules and removes the surface by chemical action. It is used at present for micro-machining metallic and non-metallic surfaces, in rubbers, polymers, papers, glass etc., for surface hardening, marking and cutting thin foils, and in eye operations to alter the contour of the cornea to correct short sight (a laser beam from the ultraviolet part of the spectrum is used).

2 kW CO_2 lasers can be used to weld up to 3 mm thick material and are an alternative to the electron beam for thin gauge material. The width of the weld may be increased at speeds below 12 mm/s due to interaction between the beam and an ionized plasma which occurs near the work. At speeds of 20 mm/s and over, laser and electron beam welds are practically indistinguishable from one another.

Stud welding

This is a rapid, reliable and economical method of fixing studs and fasteners of a variety of shapes and diameters to parent plate. The studs may be of circular or rectangular cross-section, plain or threaded internally or externally and vary from heavy support pins to clips used in component assembly.

There are two main methods of stud welding: (1) arc (drawn arc), (2) capacitor discharge, and the process selected for a given operation depends upon the size, shape and material of the stud and the composition and thickness of the parent plate, the arc method generally being used for heavier studs and plate, and capacitor discharge for lighter gauge work.

Arc (drawn arc) process

This is used in both engineering and construction work and the equipment consists of a d.c. power source, controller and a hand-operated or bench-mounted tool or gun.

A typical unit consists of a forced-draught-cooled power source with a 380/440 V, 3-phase, 50 Hz transformer, the secondary of which is connected to a full-wave, bridge-connected silicon rectifier (Vol. 1, p. 202), with tappings giving ranges of 120–180 A, 170–320 A, and 265–1500 A approximately (equipment is also available up to 1800 A), at about 65 V. The two lower ranges can also be used for MMA welding and two or more units can be connected in parallel if required, the loading being shared automatically.

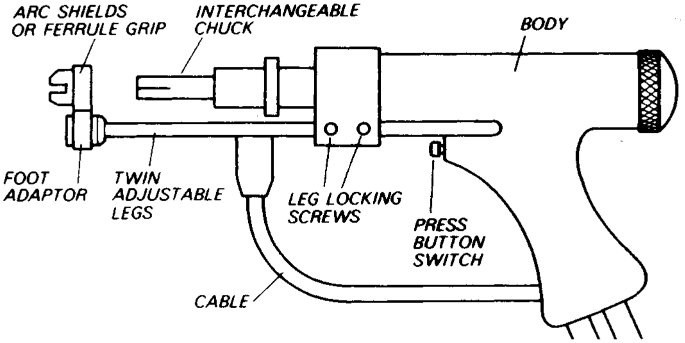
The power controller contains a main current contactor and timer relays and a pilot arc device, energized from the d.c. source. The solid-state timer has a multi-position switch or switches for the selection of operating time and current for the diameter of stud in use. Work is usually connected to the positive pole with the stud negative except for aluminium, when the polarity is reversed.

The hand gun (Fig. 5.16) has the operating solenoid and return spring within the gun body, which also carries the operating switch and adjustable legs to accommodate varying lengths of studs, an interchangeable chuck for varying stud diameters and a foot adaptor to maintain concentricity between the stud and ferrule or arc shield, this latter being held by ferrule grips. Studs are fluxed on the contact end, which is slightly pointed (Fig. 5.17), and are supplied with ferrules.

To operate the equipment, the welding current and time for the diameter of stud in use are selected, the stud is loaded into the appropriate chuck, the legs adjusted for length and the stud positioned on the plate. A centre punch can be used for locating the stud point and the plate should be free of contamination.

Sequence of operations. The gun switch is pressed, a low current flows between pointed stud end and workpiece and immediately the stud is raised, drawing an arc and ionizing the gap. The main current contactor

Fig. 5.16



now closes and full welding current flows in an arc, creating a molten state in plate and stud end. The solenoid is de-energized and the stud is pushed under controlled spring pressure into the molten pool in the plate. Finally the main current contactor opens, the current is switched off, and the operation cycle is complete, having taken only a few hundredths of a second (Fig. 5.17).

This method, which is usually employed, whereby the welding current is kept flowing until the return cycle is completed, is termed 'hot plunge'. If the current is cut off just before the stud enters the molten pool it is termed 'cold plunge'. The metal displaced during the movement of the stud into the plate is moulded into fillet form by the ceramic ferrule or arc shield held against the workpiece by the foot. This also protects the operator, retains heat and helps to reduce oxidation.

Studs from 3.3 mm to 20 mm and above in diameter can be used on parent plate thicker than 1.6 mm, and the types include split, U shaped, J bent anchors, etc. in circular and rectangular cross-section for the engineering and construction industries, and can be in mild steel (low carbon), austenitic stainless steel, aluminium and aluminium alloys (3–4% Mg). The rate of welding varies with the type of work, jigging, location, etc., but can be of the order of 8 per minute for the larger diameters and 20 per minute for smaller diameters.

(e) COMPLETED WELD

Capacitor discharge stud welding

In this process a small projection on the end of the stud makes contact with the workpiece and the energy from a bank of charged capacitors (see Volume 1) is discharged across the contact, melting the stud projection, ionizing the zone and producing a molten end on the stud and a shallow molten pool in the parent plate. At this time the stud is pushed into the workpiece under controlled spring pressure, completing the weld (Fig. 5.18).

If C is the capacitance of the capacitor, Q the charge and V the potential difference across the capacitor, then $C = Q/V$ or *capacitance = charge/potential.* The energy of a charged capacitor is $\frac{1}{2}QV$, and since $Q = CV$, the energy is $\frac{1}{2}CV^2$, so that the energy available when a capacitor is discharged is dependent upon: (1) the capacitance – the greater the capacitance the greater the energy; (2) the square of the potential difference (voltage) across the capacitance. The greater this voltage, the greater the energy. Thus the energy required for a given welding operation is obtained by selection of the voltage across the capacitor, i.e. that to which it is charged, and the total capacitance in the circuit.

In the contact method of capacitor discharge welding the small projection on the stud end is placed in contact with the workpiece as explained above. In the hold-off method, useful for thin gauge plate to avoid reverse marking, a holding coil in the hand gun is energized when the welding power is selected in the 'hold-off' position on the capacitor switch. When the stud is pushed into the gun-chuck both stud and chuck move into the hold-off position giving a pre-set clearance between the projection on the stud end and the workpiece. When the gun switch is pressed the hold-off

(d) SPRING PRESSURE FORCES STUD INTO POOL. WELD COMPLETED IN A FEW MILLISECONDS coil is de-energized and spring pressure pushes the stud into contact with the workpiece, the discharge takes place and the weld is made.

This process minimizes the depth of penetration into the parent metal surface and is used for welding smaller diameter ferrous and non-ferrous studs and fasteners to light gauge material down to 0.45 mm thickness in low-carbon and austenitic stainless steel, and 0.7 mm in aluminium and its alloys and brass, the studs being from 2.8 to 6.5 mm diameter. Studs are usually supplied with a standard flange on the end to be welded (Fig. 5.18) but this can be reduced to stud diameter if required and centre punch marks should not be used for location. The studs can be welded on to the reverse side of finished or coated sheets with little or no marking on the finished side. The studs are not fluxed and no arc shield or ferrule is required.

Typical equipment with a weld time cycle of 3–7 milliseconds consists of a control unit and a hand- or bench-mounted tool or gun.

The control unit houses the banks of capacitors of 100 000–200 000 μF capacitance depending upon the size of the unit, the capacitance required for a given operation being selected by a switch on the front panel. The control circuits comprise a charging stage embodying a mains transformer and a bridge-connected full-wave silicon rectifier and the solid-state circuits for charging the capacitors to the voltage predetermined by the voltage sensing module. Interlocking prevents the energy being discharged by operating the gun switch until the capacitors have reached the power pre-set by voltage and capacitance controls.

The printed circuit voltage sensing module controls the voltage to which the capacitors are charged and switches them out of circuit when they are charged to the selected voltage, and is controlled by a voltage dial on the panel. A panel switch is also provided to discharge the capacitors if required.

Solid-state switching controls the discharge of the capacitors between stud and work, so there are no moving contactors. The gun, similar in appearance to the arc stud welding gun, contains the adjustable spring pressure unit which enables variation to be made in the speed of return of the stud into the workpiece, and a chuck for holding the stud. Legs are provided for positioning or there can be a nosecap gas shroud for use when welding aluminium or its alloys using an argon gas shield. The weld cannot be performed until legs or shroud are firmly in contact with the workpiece.

Welding rates attainable are 12 per minute at 6.35 mm diameter to 28 per minute at 3.2 mm diameter in mild steel. Similar rates apply to stainless steel and brass but are lower for aluminium because of the necessity of argon purging. Partial scorch marks may indicate cold laps (insufficient energy) with the possibility of the stud seating too high on the work. The weld should show even scorch marks all round the stud, indicating a sound weld. Excessive spatter indicates the use of too much energy.

Automatic single- and multiple-head machines, pneumatically operated and with gravity feed for the fasteners, are currently available.

Explosive welding

This process is very successfully applied to the welding of tubes to tube plates in heat exchangers, feedwater heaters, boiler tubes to clad tube plates, etc.; and also for welding plugs into leaking tubes to seal the leaks.

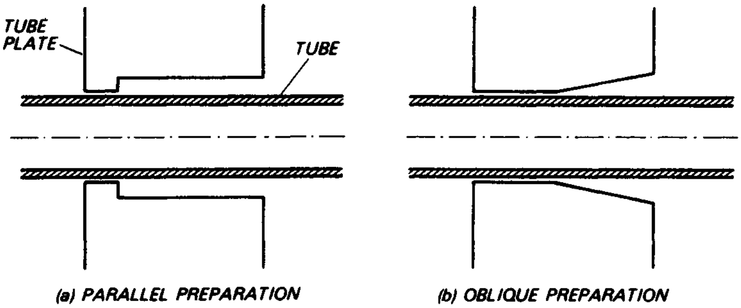
The welds made are sound and allow higher operating pressures and temperatures than with fusion welding, and the tubes may be of steel, stainless steel or copper; aluminium brass and bronze tubes in naval brass tube plates are also successfully welded.

The tube and tube plate may be parallel to each other (parallel geometry) with a small distance between them and the tube plate can be counterbored as in Fig. 5.19*a*. The explosive (e.g. trimonite) must have a low detonation velocity, below the velocity of sound in the material, and there is no limit to the joint area so that the method can be used for cladding surfaces. For the tube plate welds several charges can be fired simultaneously, the explosive being in cartridge form.

In the oblique geometry method now considered (YIMpact patent) the two surfaces are inclined at an angle to each other, Fig. 5.19*b*, the tube plate being machined or swaged as shown. As distance between tube and plate continuously increases because of the obliquity, there is a limit to the surface area which can be welded because the distance between tube and plate becomes too great.

The detonation value of the explosive can be above the velocity of sound

Fig. 5.19



(a) PARALLEL PREPARATION (b) OBLIQUE PREPARATION in the material and the explosive (e.g. PETN) can be of pre-fabricated shape and is relatively cheap. The charge is fired electrically from a fuse head on the inner end of the charge and initiates the explosion, the detonation front then passing progressively through the charge.

The size of the charge depends upon the following variables: surface finish, angle of inclination of tube and plate, yield strength and melting point of the materials, the tube thickness and diameter; and the upper limit of the explosive is dependent upon the size of ligament of the tube plate between tubes, this usually being kept to a minimum in the interest of efficient heat exchange.

The tube plate is tapered towards the outer surface otherwise there would be a bulge in the tube on the inner side after welding and the tube would be difficult to remove. The charge must be fired from the inner end so that the weld will progress from contact point of tube and plate and thus the detonator wires must pass backwards along the charge to the outer end of the tube, the charge being withn a polythene insert (Fig. 5.20*a*).

Upon initiation of the explosion, tube and tube plate collide at the inner end of the taper and, due to the release of energy, proceed along it, and ideally the jet of molten metal formed at the collision point is ejected at the tube mouth. In effect the welded surfaces assume a sinusoidal wave form, some of the molten metal, which is rather porous and brittle, being entrapped in the troughs and crests of the wave. This entrapment can be reduced to a minimum by having a good surface finish (e.g. of the order of 0.003 mm) and the angle between tube and tube plate from 10° to 15°. At the lower angle the waves are pronounced and of shorter wavelength while at the higher angle the wavelength is longer and the waves more undulating so that 15° is the usual angle (Fig. 5.20*b* and *c*).

Surface oxide and impurities between the surfaces increase the charge required compared with a smooth surface and the positioning of the charge is important. If it is too far in, the energy at the mouth of the tube is not sufficient to produce a weld in this region, while if the charge is not far enough in the tube, welding is not commenced until some distance along the taper. To position the charge correctly and quickly a polythene insert has been developed to contain the charge and is positioned by a brass plug.

At present tubes of any thickness and of diameters 16–57 mm are weldable, with ·plate thickness greater than 32 mm and 9.5 mm plate ligaments.

The plug for explosive plugging of leaking tubes is of tubular form, the end of which is swaged to give the necessary taper, the polythene insert protruding beyond the open end of the plug to allow for extraction in case of misfire, thus increasing the safety factor (Fig. 5.21).

Since all the configuration is confined to the plug, the tube plate hole is cleaned by grinding, the plug with explosive charge is inserted and the detonator wires connected. The plugs are available in diameters with 1.5 mm increments.

This method has proved very satisfactory in reducing the time and cost in repair work of this nature.

Personnel can be trained by the manufacturers or trained personnel are available under contract.

Gravity welding

This is a method for economically welding long fillets in the flat position using gravity to feed the electrode in and to traverse it along the plate. The equipment is usually used in pairs, welding two fillets at a time, one on each side of a plate, giving symmetrical welds and reducing stress and distortion. The electrode holder is mounted on a ball-bearing carriage and slides smoothly down a guide bar, the angle of which to the weld can be adjusted to give faster or slower traverse and thus vary the length of deposit of the electrode and the leg length of the weld.

The special copper alloy electrode socket is changed for varying electrode diameters and screws into the electrode holder, the electrode being pushed into a slightly larger hole in the socket and held there by the weight of the carriage. Turning the electrode holder varies the angle of electrode inclination. The base upon which the guide and support bar is mounted has two small ball bearings fitted so that it is easy to move along the base plate when resetting. If the horizontal plate is wider than about 280 mm a counterweight can be used with the base, otherwise the base can be attached to the vertical plate by means of two magnets or a jig can be used in place of the base to which the segment is fixed. A flexible cable connects the electrode holder to a disconnector switch carried on the support arm. This enables the current to be switched on and off so that electrodes can be changed without danger of shock. A simple mechanism at the bottom of the guide bar switches the arc off when the carriage reaches the bottom of its travel (Fig. 5.22).

At the present time electrodes up to 700 mm long are available in diameters of 3.5, 4.0, 4.5, 5.0 and 5.5 mm using currents of 220–315 A with rutile, rutile-basic and acid coatings suitable for various grades of steel.

Gravity welding is usually used for fillets with leg lengths of 5–8 mm, the lengths being varied by altering the length of deposit per electrode. An a.c. power source is used for each unit with an OCV of 60 and arc volts about 40 V with currents up to 300 A. Sources are available for supplying up to 6 units (three pairs), manageable by one welding operator and so arranged that when the current setting for one unit is chosen, the remaining units are supplied at this value. In general gravity welding is particularly suitable for welding, for example, long parallel stiffeners on large unit panels, enabling one operator to carry out three or four times the deposit length as when welding manually.

Thermit welding

Thermit (or alumino-thermic) is the name given to a mixture of finely divided iron oxide and powdered aluminium. If this mixture is placed in a fireclay crucible and ignited by means of a special powder, the action, once started, continues throughout the mass of the mixture, giving out great heat. The aluminium is a strong reducing agent, and combines with the oxygen from the iron oxide, the iron oxide being reduced to iron.

The intense heat that results, because of the chemical action, not only melts the iron, but raises it to a temperature of about 3000 °C. The aluminium oxide floats to the top of the molten metal as a slag. The crucible is then tapped and the superheated metal runs around the parts to be welded, which are contained in a mould. The high temperature of the iron results in excellent fusion taking place with the parts to be welded. Additions may be made to the mixture in the form of good steel scrap, or a small percentage of manganese or other alloying elements, thereby producing a good quality thermit steel. The thermit mixture may consist of about 5 parts of aluminium to 8 parts of iron oxide, and the weight of thermit used will depend on the size of the parts to be welded. The ignition

powder usually consists of powdered magnesium or a mixture of aluminium and barium peroxide.

Preparation

The ends which are to be welded are thoroughly cleaned of scale and rust and prepared so that there is a gap between them for the molten metal to penetrate well into the joint. Wax is then moulded into this gap, and also moulded into a collar round the fracture. This is important, as it gives the necessary reinforcement to the weld section. The moulding box is now placed around the joint and a mould of fireclay and sand made, a riser, pouring gate and pre-heating gate being included. The ends to be welded are now heated through the pre-heating gate by means of a flame and the wax is first melted from between the ends of the joint. The heating is continued until the ends to be welded are at red heat. This prevents the thermit steel being chilled, as it would be if it came into contact with cold metal. The pre-heating gate is now sealed off with sand and the thermit process started by igniting the powder. The thermit reaction takes up to about 1 minute, depending upon the size of the charge and the additions that have been made in the form of steel scrap and alloying elements etc. When the action is completed the steel is poured from the crucible through the pouring gate, and it flows around the red-hot ends to be welded, excellent fusion resulting. The riser allows extra metal to be drawn by the welded section when contraction occurs on cooling, that is it acts as a reservoir. The weld should be left in the mould as long as possible (up to 12 hours), since this anneals the steel and improves the weld.

Thermit steel is pure and contains few inclusions. It has a tensile strength of about 460 N/mm^2. The process is especially useful in welding together parts of large section, such as locomotive frames, ships' stern posts and rudders, etc. It is also being used in place of flash butt welding for the welding together of rail sections into long lengths.

At the present time British Rail practice is to weld 18 m long rails into lengths of 91 to 366 m at various depots by flash butt welding. These lengths are then welded into continuous very long lengths *in situ* by means of the thermit process and conductor rails are welded in the same way. Normal running rails have a cross-sectional area of 7184 mm^2 and two techniques are employed, one requiring a 7 minute pre-heat before pouring the molten thermit steel into the moulds and the other requiring only $1\frac{1}{2}$ minutes pre-heat, the latter being the technique usually employed. Excess metal can be removed by pneumatic hammer and hot chisel or by portable trimming machine.

Underwater welding

The three main methods of underwater welding at present are (1) wet, (2) localized dry chamber, (3) dry habitat (surroundings).

Wet welding

Wet welding is performed by the diver-welder normally using surface diving or saturation diving techniques using the MMA process with electrodes specially coated with insulating varnishes to keep them dry.

Current is supplied by a generator of some 400 A capacity at 60–100 OCV, directly to the welding torch head. Interchangeable collets of 4 mm and 4.8 mm ($\frac{5}{32}''$ and $\frac{3}{16}''$), hold electrodes of these diameters and are tightened by the twist-grip control, which is also used to eject the stub when electrodes are changed. Watertight glands and washers prevent seepage of water into the body of the torch, which is tough rubber covered thus reducing the danger of electric shock.

Arc stability is less than that in air due to the large volumes of gas and steam which are evolved, making vision difficult and as a result touch welding is generally used. The presence of water in the immediate vicinity of the weld except at the molten pool under the arc stream results in the very rapid quenching of the weld metal, which produces a hard, narrow heat affected zone and can give rise to severe hydrogen cracking. At present this method is used for non-critical welds, critical welding being carried out under dry conditions.

Localized dry chamber (hyperbaric)

These chambers, in which welding is performed at pressure above one atmosphere, are generally made of steel and are constructed with antichambers around the section to be welded. Water is then displaced from the chamber by gas pressure. The gas in the chamber used by the diver-welder is typically a mixture of helium and oxygen (heliox). This mixture eliminates the harmful effect of nitrogen, the helium being the carrier for the oxygen – a partial pressure of oxygen above 2 bar can be poisonous. The oxygen content is adjusted until the diver-welder does not use a breathing mask, but at the moment of welding he puts on a breathing–welding mask which has a gas supply separate from that of the chamber and umbilicals connected to the mask to enable the breathing gases to be exhausted outside the chamber.

TIG, MMA and flux cored methods of welding are used down to a depth of 300 m of water but TIG, using high purity argon as the shielding gas, is the slowest method as it is a low deposition rate process. It can be used for root runs and hot passes, but MMA or the flux cored method is used for filling and capping. Stringer bead techniques may be used to impart toughness, and temper beads to minimize HAZ hardness. Generally the high-strength, basic-coated steel electrodes which may contain iron powder are used. They are pre-heated in a drying oven immediately before use and pre-heat of about 100°C can be applied locally to the joint.

After welding, the joints are subject to X-ray or ultra-sonic testing according to the welding codes used.

Coffer dam

A coffer dam is a watertight case of steel piling erected around a given point to keep out the water. By pumping the dam dry, welding can be performed at atmospheric pressure up to about 18 m deep and welding can proceed irrespective of the state of the tides if in tidal water.

In this case the welding is performed exactly as if it were on shore and the welders are in audio and visual contact with the welding process engineer. Much of the damage to offshore platforms is in the splash zone so there is quite a saving in cost using this method as opposed to hyperbaric welding. Fig. 5.23 shows a typical underwater torch, which can also be used with small modifications for underwater cutting.

Oxy-acetylene welding

Principles and equipment

(See also pp. 323–5 for general safety precautions)

For oxy-acetylene welding, the oxygen is supplied from steel cylinders and the acetylene either from cylinders or from an acetylene generator which can be of the medium-pressure or low-pressure type.

With cylinder gas, the pressure is reduced to 0.06 N/mm^2 or under, according to the work, by means of a pressure-reducing valve and the acetylene is passed to the blowpipe where it is mixed with oxygen in approximately equal proportions, and finally passed into the nozzle or tip to be burnt.

The medium-pressure acetylene generator delivers gas to any desired pressure up to a maximum of 0.06 N/mm^2 (0.6 bar) in the same way as cylinder gas.

The low-pressure generator produces gas at a pressure of only a few millimetres water column, necessitating the use of 'injector' blowpipes where the high-pressure oxygen injects or sucks the acetylene into the blowpipe. In some cases, as for example if the supply pipes are small for the volume of gas to be carried or if it is desirable to use the equal pressure type of blowpipe, a booster is fitted to the low-pressure generator and the gas pressure increased to 0.06 N/mm^2.

Without Home Office approval, the maximum pressure at which acetylene may be used in England is 0.06 N/mm^2. With approval, the pressure may be increased to 0.15 N/mm^2, but this is rare and applies only in special cases.

Oxygen

The oxygen for both high- and low-pressure systems is supplied in solid drawn steel cylinders at pressures up to 200 bar at 15 °C.* The cylinders are rated according to the amount of gas they contain, varying from 0.68 m^3 at a pressure of 137 bar to 9.66 m^3 at 200 bar.

---

* *Note.* 1 bar = 0.1 N/mm^2 = approximately 15 lbf/in^2.

The volume of oxygen contained in the cylinder is approximately proportional to the pressure; hence for every 10 litres of oxygen used, the pressure drops about 0.02 N/mm^2. This enables us to tell how much oxygen remains in a cylinder. The oxygen cylinder is provided with a valve threaded right hand and is painted black. On to this valve, which contains a screw-type tap, the pressure regulator and pressure gauge are screwed. The regulator adjusts the pressure to that required at the blowpipe. Since grease and oil can catch fire spontaneously when in contact with pure oxygen under pressure, they must never be used on any account upon any part of the apparatus. Leakages of oxygen can be detected by the application of a soap solution, when the leak is indicated by the soap bubbles. Never test for leakages with a naked flame.

Liquid oxygen

Liquid oxygen, nitrogen, argon and LPG are available in bulk supply from tankers to vacuum-insulated evaporators (VIE) in which the liquid is stored at temperatures of −160 to −200°C and are very convenient for larger industrial users.

There is no interruption in the supply of gas nor drop in pressure during filling.

The inner vessel, of austenitic stainless steel welded construction, has dished ends and is fitted with safety valve and bursting disc and is available in various sizes with nominal capacities from 844 to 33 900 m^3. Nominal capacity is the gaseous equivalent of the amount of liquid that the vessel will hold at atmospheric pressure. The outer vessel is of carbon steel and fitted with pressure release valve. The inner vessel is vacuum and pearlite insulated from the outer vessel, thus reducing the thermal conductivity to a minimum. The inner vessel *A* (Fig. 6.1) contains the liquid with gas above, and gas is withdrawn from the vessel through the gaseous withdrawal line *B* and rises to ambient temperature in the superheater-vaporizer *C*, from which it passes to the supply pipeline. If the pressure in the supply falls below the required level the pressure control valve *D* opens and liquid flows under gravity to the pressure-raising vaporizer *E*, where heat is absorbed from the atmosphere, and the liquid vaporizes and passes through the gas withdrawal point *H* raising the pressure to the required pre-set level which can be up to 1.7 N/mm^2 (250 lbf/in^2), and the valve *D* then shuts.

In larger units, to allow for heavy gas demand, when the pressure falls on the remote side of the restrictive plate *F*, liquid flows from the vessel via the withdrawal line *G* and passes to the superheater-vaporizer where it changes to the gaseous form and is heated to ambient temperature, finally passing to the pipeline.

During periods when the VIE is not in use the valve *D* remains shut. Heat from the outside atmosphere gradually flows through the insulation between the vessels so that more liquid is vaporized and the pressure of the gas rises. This rate of heat leakage is slow, however, and it usually takes about seven days for the pressure to rise sufficiently to lift the safety valve, so that under normal working conditions there is almost zero loss.

Acetylene

In the high-pressure system the acetylene is stored in steel cylinders similar to the oxygen cylinders. Acetylene gas, however, is unstable when compressed to high pressures, and because of this it is contained in the bottles dissolved in a chemical called acetone; hence the name 'dissolved acetylene'.

The acetone is contained in a porous spongy mass of a substance such as charcoal, asbestos, kapok or other such material. Acetone can absorb 25 times its own volume of acetylene at normal temperature and pressure and for every increase of one atmosphere of pressure (0.1 N/mm^2 or 1 bar) it can absorb an equal amount.

FILLING COUPLING

The inlet pressure of the acetylene is usually about 20 bar maximum, typical capacities varying from 0.57 to 8.69 m^3, depending on the cylinder type. The gas leaves the cylinder through a valve after passing through a filter pad. The valve has a screw tap fitted and is screwed left-hand. The cylinder is painted maroon and a regulator (also screwed left-hand) is necessary to reduce the pressure to 1.3 bar maximum as required by the operator.

The amount of dissolved acetylene in a cylinder cannot be determined with any accuracy from the pressure gauge reading since it is in the dissolved condition. The most accurate way to determine the quantity of gas in a cylinder is to weigh it, and subtract this weight from the weight of the full cylinder, which is usually stamped on the label attached to the cylinder. The volume of gas remaining in the cylinder is calculated by remembering that 1 litre of acetylene weighs 1.1 g.

As long as the volume of acetylene drawn from the cylinder is not greater than $\frac{1}{5}$ of its capacity per hour, there is no appreciable amount of acetone contained in gas; hence this rate of supply should not be exceeded. The advantages of dissolved acetylene are that no licence is required for storage of the cylinders, there is no fluctuation of pressure in use, and the gas is always dry, clean and chemically pure, resulting in a reliable welding flame, and it avoids the need to charge and maintain a generator and to dispose of the sludge. There is no discernible difference in efficiency between generated and dissolved acetylene when both are used under normal conditions. Acetylene is highly inflammable and no naked lights should be held near a leaking cylinder, valve or tube. Leaks can be detected by smell or by soap bubbles. If any part of the acetylene apparatus catches fire, immediately shut the acetylene valve on the cylinder. The cylinder should be stored and used in an upright position.

The following is a summary of the main safety precautions to be taken when storing and using cylinders of compressed gas.

Storage

(1) Store in a well ventilated, fire-proof room with flame-proof electrical fittings. Do not smoke, wear greasy clothing or have exposed flames in the storage room.

(2) Protect cylinders from snow and ice and from the direct rays of the sun, if stored outside.

(3) Store away from sources of heat and greasy and oily sources. (Heat increases the pressure of the gas and may weaken the cylinder wall. Oil and grease may ignite spontaneously in the presence of pure oxygen.)

(4) Store acetylene cylinders in an upright position and do not store oxygen and combustible gases such as acetylene and propane together.
(5) Keep full and empty cylinders apart from each other.
(6) Avoid dropping and bumping cylinders violently together.

Use

(7) Keep cylinders away from electrical apparatus or live wires where there may be danger of arcing taking place.
(8) Protect them from the sparks and flames of welding and cutting operations.
(9) Always use pressure-reducing regulators to obtain a supply of gas from cylinders.
(10) Make sure that cylinder outlet valves are clear of oil, water and foreign matter, otherwise leakage may occur when the pressure-reducing regulators are fitted.
(11) Do not use lifting magnets on the cylinders. Rope slings may be used on single cylinders taking due precautions against the cylinder slipping from the sling. Otherwise use a cradle with chain suspension.
(12) Deload the diaphragm of the regulator by unscrewing before fitting to a full cylinder, and open the cylinder valve slowly to avoid sudden application of high pressure on to the regulator.
(13) Do not overtighten the valve when shutting off the gas supply; just tighten enough to prevent any leakage.
(14) Always shut off the gas supply when not in use for even a short time, and always shut off when moving cylinders.
(15) Never test for leaks with a naked flame; use soapy water.
(16) Make sure that oxygen cylinders with round bases are fastened when standing vertically, to prevent damage by falling.
(17) Thaw out frozen spindle valves with hot water NOT with a flame.
(18) Use no copper or copper alloy fitting with more than 70% copper because of the explosive compounds which can be formed when in contact with acetylene.
(19) Do not use oil or grease or other lubricant on valves or other apparatus, and do not use any jointing compound.
(20) Blow out the cylinder outlet by quickly opening and closing the valve before fitting the regulator.
(21) Should an acetylene cylinder become heated due to any cause, immediately take it outdoors, immerse in water or spray it with water, open the valve and keep as cool as possible until the cylinder is empty. Then contact the suppliers.

(22) Do not force a regulator on to a damaged outlet thread. Report damage to cylinders to the suppliers.

Note. Also refer to Form 1704, 'Safety measures required in the use of acetylene gas and in oxy-acetylene processes in factories' (HMSO) and also 'Safety in the use of compressed gas cylinders', a booklet published by the British Oxygen Gases Ltd.

The cylinder outlet union is screwed left hand for combustible gases and right hand for non-combustible gases, the thread being $\frac{5}{8}$ in (16 mm) BSP except for CO_2 which is 21.8 mm, 14 TPI male outlet.

Acetylene (dissolved) is contained in a maroon coloured cylinder with the name ACETYLENE. Oxygen (commercial) is contained in a black coloured cylinder. (See Appendix 3 for full description of colour codes used on cylinders (BS 349, BS 381 C).) Consult BS 679, Gas welding filters (GWF) for the correct shade of filter for eye protection and pp. 323–5.

Medium-pressure acetylene generators

The medium-pressure generator uses small granulated carbide. 50 kg of good calcium carbide will produce about 14 000 litres of acetylene, an average practical value being 250 litres of acetylene per kilogram of carbide. The most popular sizes are 20/50 mm, 15/25 mm and 10/15 mm. The generator is self-contained (i.e. there is no separate gas holder) and consists of a water tank surmounted by a carbide hopper, in the top of which is a diaphragm. The carbide feed valve is controlled by the diaphragm, which is actuated by the pressure of the gas generated in the tank. When the pressure falls, carbide flows into the tank; as the pressure builds up the flow ceases. The gas pressure at which the generator will work is adjusted by means of a spring fitted to the opposite side of the diaphragm, ensuring close control of pressure with generation strictly in accordance with the demand. The carbide hopper is either made of glass or is fitted with windows so that the quantity of carbide remaining in the hopper can be ascertained at a glance.

Owing to the relatively large volume of water into which the small grains of carbide fall, there is no possibility of overheating and the carbide is completely slaked. The sludge, which collects at the bottom of the tank, and is emptied each time the generator is charged, consists of a thin milky fluid.

The impurities in crude acetylene consist chiefly of ammonia, hydrides of phosphorus, sulphur and nitrogen, and there are also present water vapour and particles of lime.

These impurities must be removed before the gas is suitable for welding use; the gas is filtered and washed and chemically purified by passing it through salts of ferric iron.

The normal method of testing acetylene to ascertain whether it is being efficiently purified is to hold a silver nitrate test paper (a piece of filter paper soaked in a solution of silver nitrate) in the stream of gas for about 10 seconds. If the acetylene is being properly purified, there will be no trace of stain on the silver nitrate paper.

The reducing valve or pressure regulator

In order to reduce the pressure of either oxygen or dissolved acetylene from the high pressure of the storage cylinder to that required at the blowpipe, a regulator or reducing valve is necessary. Good regulators are essential to ensure the even flow of gas to the blowpipe. A reference to Fig. 6.2 will make the principle of operation of the regulator clear. The gas enters the regulator at the base via a fine sintered metal filter and the cylinder pressure is indicated on the first gauge. The gas then enters the body of the regulator *R* through the aperture *A*, which is controlled by the

valve *V*. The pressure inside the regulator rises until it is sufficient to overcome the pressure of the spring *S*, which loads the diaphragm *D*. The diaphragm is therefore pushed back and the valve *V*, to which it is attached, closes the aperture *A* and prevents any more gas from entering the regulator.

The outlet side is also fitted with a pressure gauge (although in some cases this may be dispensed with) which indicates the working pressure on the blowpipe. Upon gas being drawn off from the outlet side the pressure inside the regulator body falls, the diaphragm is pushed back by the spring, and the valve opens, letting more gas in from the cylinder. The pressure in the body *R* therefore depends on the pressure of the springs and this can be adjusted by means of a regulator as shown.

Regulator bodies are made from brass forgings and single stage regulators are fitted with one safety valve set to relieve pressures of 16–20 bar, and should it be rendered inoperative, as for example by misuse, it ruptures at pressures of 70–80 bar and vents to the atmosphere through a vent in the bonnet. Single-stage regulators are suitable for general welding with maximum outlet pressure of 2.1 bar and for scrap cutting and heavy-duty cutting, thermic lancing and boring with outlet pressures 8.3–14 bar.

Figure 6.3*a*, *b* and *c* shows a two-stage regulator. This reduces the pressure in two stages and gives a much more stable output pressure than the single-stage regulator.

It really consists of two single stages in series within one body forging. The first stage, which is pre-set, reduces the pressure from that of the cylinder to 23 bar, and gas at that pressure passes into the second stage, from which it emerges at a pressure set by the pressure-adjusting control screw attached to the diaphragm. High-pressure regulators except those for acetylene and carbon dioxide are designed for inlet pressures of 230 bar and tested to four times working pressure. A high-flow safety relief valve is fitted and ensures that any abnormal pressures are quickly vented to atmosphere, the valve reseating itself when pressures return to normal. If a safety valve is blowing, the main valve is not seating and the regulator should immediately be taken out of service and sent for overhaul. Needle-type control valves can be fitted to regulator outlets.

The correct blowpipe pressure is obtained by adjusting the pressure of the spring with the control knob and noting the pressure in bar on the blowpipe pressure gauge. On changing a tip the regulator is set with its finger on the tip number on the scale, and final accurate adjustment of the flame is made with the blowpipe regulating valves. This is a simple and convenient method. The regulators are supplied with a table indicating the suitable pressures for various nozzles, which are stamped with their consumption of gas in litres per minute or suitable numbers. With practice the welder soon recognizes the correct pressures for various tips without reference to the table.

Regulators can be obtained for a wide variety of gases (given here with maximum outlet pressures): oxygen (welding and medium cutting and heating 3.5 bar, heavy cutting and heating 10 bar); acetylene (1.3 bar); argon (3.5 bar); nitrogen (3.5 bar); propane (heavy cutting and heating 3.5 bar); hydrogen (3.5 bar, for pressurizing 10 bar); carbon dioxide (10 bar).

To enable two, three or more cylinders of gas to be connected together, as may be required when heavy cutting work is to be done and the oxygen consumption is very great, special adaptors are available, and these feed the bottles into one gauge. In this way a much steadier supply of oxygen is obtained.

Two operators may also be fed from one cylinder of oxygen or acetylene by using a branched gauge with two regulators. The type of branched gauge which has only one regulator feeding two outlet pipes is not recommended, since any alteration of the blowpipe pressure by one operator will affect the flame of the other operator.

Owing to the rapid expansion of the oxygen in cases where large

quantities are being used, the regulator may become blocked with particles of ice, causing stoppage. This happens most frequently in cold weather, and can be prevented by use of an electric regulator heater. The heater screws into the cylinder and the regulator screws into the heater. The heater is plugged into a source of electric supply, the connexion being by flexible cable.

Hoses

Hoses are usually of a seamless flexible tube reinforced with plies of closely woven fabric impregnated with rubber and covered overall with a tough, flexible, abrasion-resistant sheath giving a light-weight hose. They are coloured blue for oxygen, red for fuel gases, black for non-combustible gases and orange for LPG, Mapp and natural gas. Available lengths are from 5 to 20 m, with bore diameters 4.5 mm for maximum working pressure of 7 bar, 8 mm for a maximum of 12 bar and 10 mm for a maximum working pressure of 15 bar. Nipple- and nut-type connexions and couplers are available for 4.5 mm ($\frac{3}{8}$ in.), 8 and 10 mm hoses with 6.4 mm ($\frac{1}{4}$ in. BSP) and 10 mm ($\frac{3}{8}$ in. BSP) nuts. A hose check valve is used to prevent feeding back of gases from higher or lower pressures and reduces the danger of a flashback due to a blocked nozzle, leaking valve, etc. It is connected in the hose at the blowpipe end or to the economizer or regulator, and consists of a self-aligning spring-loaded valve which seals off the line in the event of backflow. BS 924 J and 796 J apply to hoses.

The welding blowpipe or torch

There are two types of blowpipes: (1) high pressure, (2) low pressure, and each type consists of a variety of designs depending on the duty for which the pipe is required. Special designs are available for rightward and leftward methods of welding (the angle of the head is different in these designs), thin gauge or thick plate, etc., in addition to blowpipes designed for general purposes.

The high-pressure blowpipe is simply a mixing device to supply approximately equal volumes of oxygen and acetylene to the nozzle, and is fitted with regulating valves to vary the pressure of the gases as required (Fig. 6.4*a*, *b*). A selection of shanks is supplied with each blowpipe, having orifices of varying sizes, each stamped with a number or with the consumption in litres per hour (l/h). Various sizes of pipes are available, from a small light variety, suitable for thin gauge sheet, to a heavy duty pipe. A high-pressure pipe cannot be used on a low-pressure system.

The low-pressure blowpipe has an injector nozzle inside its body through which the high-pressure oxygen streams (Fig. 6.5). This oxygen draws the

low-pressure acetylene into the mixing chamber and gives it the necessary velocity to preserve a steady flame, and the injector also helps to prevent backfiring. The velocity of a 1/1 mixture of oxygen/acetylene may be 200 m per minute, while the maximum gas velocity occurs for a 30% acetylene mixture and may be up to 460 m per min. (These figures are approximate only.)

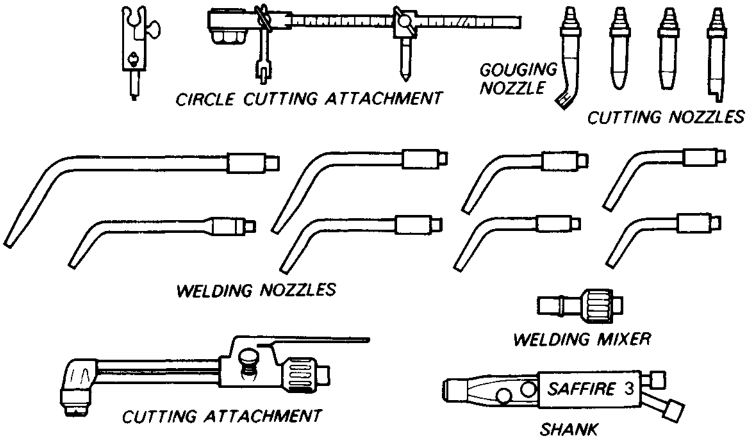
It is usual for the whole head to be interchangeable in this type of pipe, the head containing both nozzle and injector. This is necessary, since there is a corresponding injector size for each nozzle. Regulating valves, as on the high-pressure pipes, enable the gas to be adjusted as required. The low-pressure pipe is more expensive than the high-pressure pipe; and it can be used on a high-pressure system if required, but it is now used on a very small scale.

A very useful type of combined welding blowpipe and metal-cutting torch is shown in Fig. 6.6. The shank is arranged so that a full range of nozzles, or a cutting head, can be fitted. The design is cheaper than for a corresponding separate set for welding and cutting, and the cutter is sufficient for most work.

The oxy-acetylene flame

The chemical actions which occur in the flame have already been discussed in Volume 1, and we will now consider the control and regulation of the flame to a condition suitable for welding.

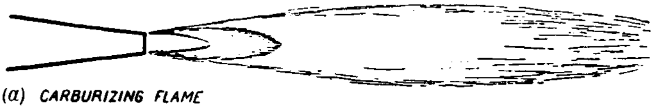
Fig. 6.6. Combined welding and cutting pipes. Will weld sections from 1.6 mm to 32 mm thick, and cut steel up to 150 mm thick with acetylene and 75 mm with propane.



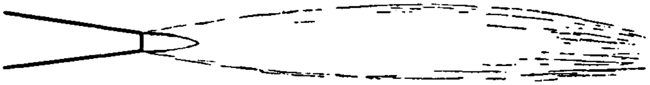
Adjustment of the flame.[*] To adjust the flame to the neutral condition the acetylene is first turned on and lit. The flame is yellow and smoky. The acetylene pressure is then increased by means of the valve on the pipe until the smokiness has just disappeared and the flame is quite bright. The condition gives approximately the correct amount of acetylene for the particular jet in use. The oxygen is then turned on as quickly as possible, and as its pressure is increased the flame ceases to be luminous. It will now be noticed that around the inner blue luminous cone, which has appeared on the tip of the jet, there is a feathery white plume which denotes excess acetylene (Fig. 6.7*a*). As more oxygen is supplied this plume decreases in size until there is a clear-cut blue cone with no white fringe (Fig. 6.7*b*). This is the neutral flame used for most welding operations. If the oxygen supply is further increased, the inner blue cone becomes smaller and thinner and the outer envelope becomes streaky; the flame is now oxidizing (Fig. 6.7*c*). Since the oxidizing flame is more difficult to distinguish than the carbonizing or carburizing (excess acetylene) flame, it is always better to start with excess acetylene and increase the oxygen supply until the neutral condition is reached, than to try to obtain the neutral flame from the oxidizing condition.

Some welders prefer to regulate the oxygen pressure at the regulator itself. The acetylene is lighted as before, and with the oxygen valve on the blowpipe turned full on, the pressure is adjusted correctly at the regulator until the flame is neutral. In this way the welder is certain that the regulator is supplying the correct pressure to the blowpipe for the particular nozzle being used.

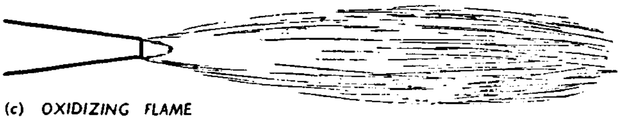
Fig. 6.7



(*a*) CARBURIZING FLAME



(*b*) NEUTRAL FLAME



(c) OXIDIZING FLAME

---

[*] The pressure on oxygen and acetylene gauges is approximately that given in the table on p. 276.

Selection of correct nozzle. As the thickness of the work to be welded increases, the flame will have to supply more heat, and this is made possible by increasing the size of the nozzle. The nozzle selected may cover one or two thicknesses of plate; for example, a nozzle suitable for welding 6.4 mm plate will weld both 4.8 mm and 8 mm plate by suitable regulation of the pressure valves. This is because the blowpipe continues to mix the gases in the correct proportion over a range of pressures. If, however, one is tempted to weld a thickness of plate with a nozzle which is too large, by cutting down the supply of gas at the valves instead of changing the nozzle for one smaller, it will be noticed that explosions occur at the nozzle when welding, these making the operation impossible. These explosions indicate too low a pressure for the nozzle being used.

If, on the other hand, one attempts to weld too great a thickness of metal with a certain nozzle, it will be noticed that as one attempts to increase the pressure of the gases beyond a certain point to obtain a sufficiently powerful flame, the flame leaves the end of the nozzle. This indicates too high a pressure and results in a *hard* noisy flame. It is always better to work with a soft flame which is obtained by using the correct nozzle and pressure. Thus, although there is considerable elasticity as to the thickness weldable with a given nozzle, care should be taken not to overtax it.

Use and care of blowpipe

Oil or grease should upon no account be used on any part of the blowpipe, but a non-oily graphite may be used and is useful for preventing wear and any small leaks.

A backfire is the appearance of the flame in the neck or body of the blowpipe and which rapidly extinguishes itself.

A flashback is the appearance of the flame beyond the blowpipe body into the hose and even the gauge, with subsequent explosion. It can be prevented by fitting a flashback arrestor.

Backfiring may occur at the pipe through several causes:

(1) Insufficient pressure for the nozzle being used. This can be cured by increasing the pressure on the gauge.

(2) Metal particles adhering to the nozzle. The nozzle can be freed of particles by rubbing it on a leather or wooden surface. (The gases should be first shut off and then relit.)

(3) The welder touching the plate or weld metal with the nozzle. In this case the gases should be shut off and then relit.

(4) Overheating of the blowpipe. A can of water should be kept near so as to cool the nozzle from time to time, especially when using a large flame. Oxygen should be allowed to pass slowly through the

nozzle, when immersed in the water, to prevent the water entering the inside of the blowpipe.

(5) Should the flame backfire into the mixing chamber with a squealing sound, and a thin plume of black smoke be emitted from the nozzle, serious damage will be done to the blowpipe unless the valves are immediately turned off. This fault may be caused by particles having lodged inside the pipe, or even under the regulating valves. The pipe should be thoroughly inspected for defects before being relit.

In the event of a backfire, therefore, immediately shut off the acetylene cylinder valve, and then the oxygen, before investigating the cause.

Blowpipe nozzles should be cleaned by using a soft copper or brass pin. They should be taken off the shank and cleaned from the inside, as this prevents enlarging the hole. A clean nozzle is essential, since a dirty one gives an uneven-shaped flame with which good welds are impossible to make. Special sets of reamers can be obtained for this work.

Flashback arrestor

Note. Flashback arrestors should be fitted to all welding equipment. A flashback occurs when the flame moves from the blow torch into the supply system against the flow of the gases. It is potentially dangerous and its effects can range from sooty deposits in the blowpipe and hoses to a fire in the gauge or cylinder often accompanied by squealing or popping noises. It is generally due to incorrect operating practice such as overheated blowpipe and wrong pressures.

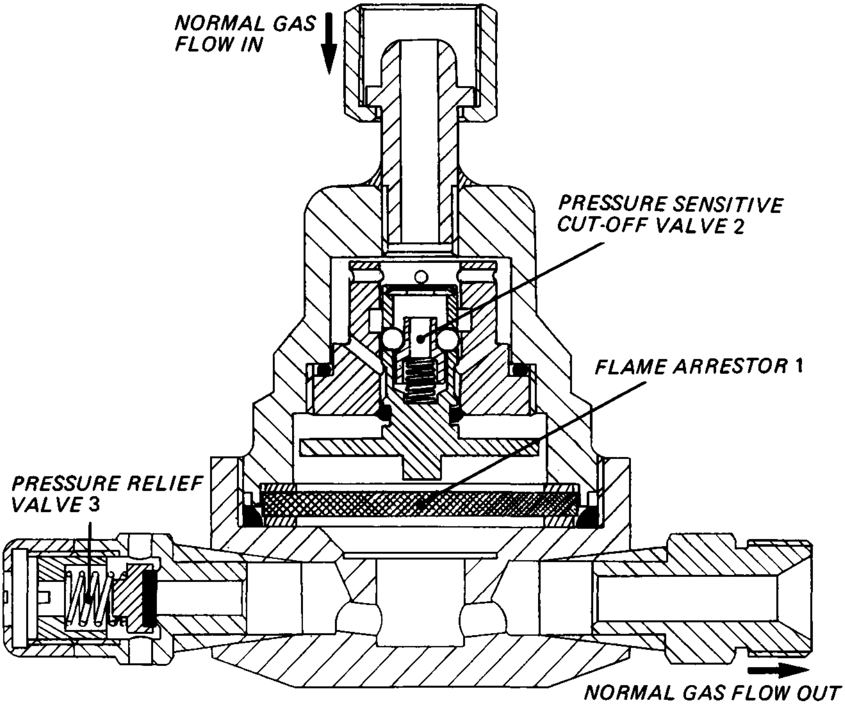
The automatic flashback arrestor is made for acetylene, propane, hydrogen, and oxygen and is generally connected to the regulator outlet (Fig. 6.3*c*) and prevents flame movement into gauges and cylinder, causing regulator damage and even cylinder fires.

A dense sintered stainless steel plate filter of up to 100 micron mesh (1) in Fig. 6.8*a* arrests the flame and is designed to quench the flame from even the most violent explosion of the gas mixture. The large surface area of the filter does not offer much resistance to the forward flow of the gas. The pressure-sensitive cut-off valve (2) automatically cuts off the supply of gas to the blow torch preventing sustained flashback and it will remain closed until it is set manually, a spring plus the gas pressure holding it closed. There should never be any attempt to reset the valve until the cause of the flashback has been thoroughly investigated and put right and it cannot be reset until the pressure is taken off the system, so close the cylinder valve to cut off the supply at source. To reset, on the model shown, the reset pin (attached to the gauge by a chain to prevent loss) is inserted into the gas inlet orifice, centred against the valve and pushed hard home resetting the valve mechanism. On some models there is a visible lever which is actuated when the arrestor cut-off valve operates. This lever actuates the mechanism but should never be reset until the cause of the flashback is determined and put to rights.

After several actuations, carbon deposits may interfere with the correct functioning of the arrestor so it should be exchanged. Arrestors are generally used up to oxygen pressures of 10 bar, propane of 5 bar and acetylene of 1.5 bar.

Operation. The spring-loaded valve (or piston) is held by a low melting point solder against the tension of a spring. If a flashback occurs the temperature rising to 120–150 °C melts the solder and the non-return valve is forced onto its seat and prevents further reverse flow of gas. There is little restriction of gas flow under normal working conditions but in the case of the piston being activated the whole unit must be replaced (Figs. 6.8*b*, *c*).

Fig. 6.8. (*a*) Section through resettable flashback arrestor.



Technique of welding

Before attempting any actual welding operations, the beginner should acquire a sense of fusion and a knowledge of blowpipe control. This can be obtained by running lines of fusion on thin-gauge steel plate.

The flame is regulated to the neutral condition and strips of 1.6 or 2 mm steel plate are placed on firebricks on the welding bench. Holding the blowpipe at approximately 60° to the plate, with the inner blue cone near the metal surface, and beginning a little from the right-hand edge of the sheet, the metal is brought to the melting point and a puddle formed with a rotational movement of the blowpipe. Before the sheet has time to melt through into a hole, the pipe is moved steadily forward, still keeping the steady rotating motion, and the line of fusion is made in a straight line. This exercise should be continued on various thicknesses of thin-gauge plate until an even line is obtained, and the underside shows a regular continuous bead, indicating good penetration, the student thus acquiring a sense of fusion and of blowpipe control.

In the following pages various methods of welding techniques are considered, and it would be well to state at this point what constitutes a good weld, and what features are present in a bad weld.

Fig. 6.9*a* indicates the main features of a good fusion weld, with the following features:

(*a*) Good fusion over the whole side surface of the V.
(*b*) Penetration of the weld metal to the underside of the parent plate.
(*c*) Slight reinforcement of the weld above the parent plate.
(*d*) No entrapped slag, oxide, or blowholes.

Fig. 6.9*b* indicates the following faults in a weld:

(*a*) Bad flame manipulation and too large a flame has caused molten metal to flow on to unfused plate, giving no fusion (i.e. adhesion).
(*b*) Wrong position of work, incorrect temperature of molten metal, and bad flame manipulation has caused slag and oxide to be entrapped and channels may be formed on each line of fusion, causing undercutting.
(*c*) The blowpipe flame may have been too small, or the speed of welding too rapid, and this with lack of skill in manipulation has caused bad penetration.

(N.B. Reinforcement on the face of a weld *will not* make up for lack of penetration.)

Methods of welding

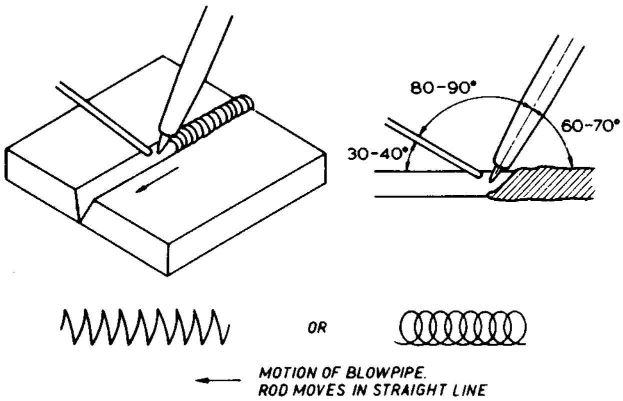
Leftward or forward welding

This method is used nowadays for welding steel plate under 6.5 mm thick and for welding non-ferrous metals. The welding rod precedes the blowpipe along the seam, and the weld travels from right to left when the pipe is held in the right hand. The inner cone of the flame, which is adjusted to the neutral condition, is held near the metal, the blowpipe making an angle of 60 to 70° with the plate, while the filler rod is held at an angle of 30 to 40°. This gives an angle of approximately 90° between the rod and the blowpipe. The flame is given a rotational, circular, or side-to-side motion, to obtain even fusion on each side of the weld. The flame is first played on the joint until a molten pool is obtained and the weld then proceeds, the rod being fed into the molten pool and not melted off by the flame itself. If the flame is used to melt the rod itself into the pool, it becomes easy to melt off too much and thus reduce the temperature of the molten pool in the parent metal to such an extent that good fusion cannot be obtained. Fig. 6.10 will make this clear.

The first exercise in welding with the filler rod is done with the technique just described and consists of running lines of weld on 1.6 or 2 mm plate, using the filler rod. Butt welds of thin plate up to 2.4 mm can be made by flanging the edges and melting the edges down. When a uniform weld is obtained, with good penetration, the exercises can be repeated on plate up to 3.2 mm thick, and butt welds on this thickness attempted. Above 3.2 mm thick, the plates are bevelled, chamfered, or V'd to an angle of 80 to 90° (Fig. 6.11). The large area of this V means that a large quantity of weld metal is required to fill it. If, however, the V is reduced to less than 80°, it is found

Fig. 6.10. Leftward welding.

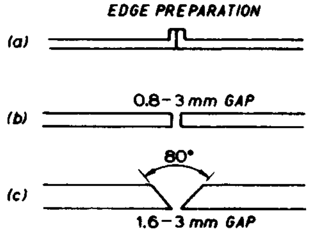


that as the V becomes narrower the blowpipe flame tends to push the molten metal from the pool, forward along onto the unmelted sides of the V, resulting in poor fusion or adhesion. This gives an unsound weld, and the narrower the V the greater this effect.

As the plate to be welded increases in thickness, a larger nozzle is required on the blowpipe, and the control of the molten pool becomes more difficult; the volume of metal required to fill the V becomes increasingly greater, and the size of nozzle which can be used does not increase in proportion to the thickness of the plate, and thus welding speed decreases. Also with thicker plates the side-to-side motion of the blowpipe over a wide V makes it difficult to obtain even fusion on the sides and penetration to the bottom, while the large volume of molten metal present causes considerable expansion. As a result it is necessary to weld thicker plate with two or more layers if this method is used. From these considerations it can be seen that above 6.4 mm plate the leftward method suffers from several drawbacks. It is essential, however, that the beginner should become efficient in this method before proceeding to the other methods, since for general work, including the non-ferrous metals (see later), it is the most used.

Edge preparation (Letters refer to Fig. 6.11)	Thickness of plate (mm)	Nozzle size (mm)	Oxygen and acetylene pressure (bar)	Oxygen and acetylene gas consumption (l/h)
(*a*)	0.9–1.6	0.9–1	0.14	28
		1.2–2	0.14	57
(*b*)	2.4–3.0	2–3	0.14	86
		2.6–5	0.14	140
(*c*)	3.0–4.0	3.2–7	0.14	200
		4.0–10	0.21	280

Fig. 6.11. Leftward welding: edge preparations.



The preparation of various thicknesses of plate for butt joints by the leftward method is given in the table accompanying Fig. 6.11.

Rightward welding

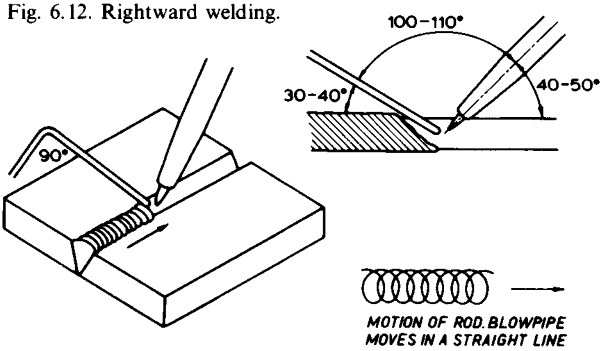
This method was introduced some years ago to compete with electric arc welding in the welding of plate over 4.8 mm thick, since the leftward method has the disadvantage just mentioned on welding thick plate. This method has definite advantages over the leftward method on thick plate, but the student should be quite aware of its limitations and use it only where it has a definite advantage.

In this method the weld progresses along the seam from left to right, the rod following the blowpipe. The rod is given a rotational or circular motion, while the blowpipe moves in practically a straight line, as illustrated in Fig. 6.12. The angle between blowpipe and rod is greater than that used in the leftward method.

When using this method good fusion can be obtained without a V up to 8 mm plate. Above 8 mm the plates are prepared with a 60° V, and since the blowpipe has no side motion the heat is all concentrated in the narrow V, giving good fusion. The blowpipe is pointing backwards towards the part that has been welded and thus there is no likelihood of the molten metal being pushed over any of the unheated surface, giving poor fusion.

A larger blowpipe nozzle is required for a given size plate than in leftward welding, because the molten pool is controlled by the pipe and rod but the pipe has no side to side motion. This larger flame gives greater welding speed, and less filler rod is used in the narrower V. The metal is under good control and plates up to 16 mm thick can be welded in one pass. Because the blowpipe does not move except in a straight line, the molten metal is agitated very little and excess oxidation is prevented. The flame playing on the metal just deposited helps to anneal it, while the smaller volume of molten metal in the V reduces the amount of expansion. In

Fig. 6.12. Rightward welding.



addition, a better view is obtained of the molten pool, resulting in better penetration.

It is essential, however, in order to ensure good welds by this method, that blowpipe and rod should be held at the correct angle, the correct size nozzle and filler rod used, and the edges prepared properly (Fig. 6.13). The rod diameter is about half the thickness of the plate being welded up to 8 mm plate, and half the thickness + 0.8 mm when welding V'd plate. The blowpipe nozzle is increased in size from one using about 300 litres per hour, with the leftward method, to one using about 350 litres per hour, when welding 3.2 mm plate. If too large diameter filler rods are used, they melt too slowly causing poor penetration, and poor fusion. Small rods melt too quickly and reinforcement of the weld is difficult. Rightward welding has no advantage on plates below 6.4 mm thick and is rarely used below this thickness, the leftward method being preferred.

The advantages of the rightward method on thicker plate are:

(1) Less cost per metre run due to less filler rod being used and increased speed.
(2) Less expansion and contraction.
(3) Annealing action of the flame on the weld metal.
(4) Better view of the molten pool, giving better control of the weld.

See later for 'all-position rightward welding'.

Edge preparation (Letters refer to Fig. 6.13)	Thickness of plate (mm)	Nozzle size (mm)	Oxygen and acetylene pressure (bar)	Oxygen and acetylene gas consumption (1/h)

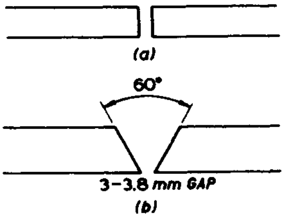
		13–45	0.35 (heavy duty mixer)	1300

Fig. 6.13. Rightward welding: edge preparations.



Vertical welding

The preparation of the plate for welding greatly affects the cost of the weld, since it takes time to prepare the edges, and the preparation given affects the amount of filler rod and gas used. Square edges need no preparation and require a minimum of filler rod. In leftward welding square edges are limited to 3.2 mm thickness and less. In vertical welding, up to 4.8 mm plate can be welded with no V'ing with the single-operator method while up to 16 mm plate can be welded with no V'ing with the two-operator method, the welders working simultaneously on the weld from each side of the plate. The single-operator method is the most economical up to 4.8 mm plate.

The single-operator method (up to 4.8 mm plate) requires more skill in the control of the molten metal than in downhand welding. Welding is performed either from the bottom upwards, and the rod precedes the flame as in the leftward method, or from the top downwards, in which case the metal is held in place by the blowpipe flame. This may be regarded as the rightward method of vertical welding, since the flame precedes the rod down the seam. In the upward method the aim of the welder is to use the weld metal which has just solidified as a 'step' on which to place the molten pool. A hole is first blown right through the seam, and this hole is maintained as the weld proceeds up the seam, thus ensuring correct penetration and giving an even back bead.

In the vertical welding of thin plate where the edges are close together, as for example in a cracked automobile chassis, little filler rod is needed and the molten pool can be worked upwards using the metal from the sides of the weld. Little blowpipe movement is necessary when the edges are close together, the rod being fed into the molten pool as required. When the edges are farther apart, the blowpipe can be given the usual semicircular movement to ensure even fusion of the sides.

From Fig. 6.14 it will be noted that as the thickness of the plate increases, the angle of the blowpipe becomes much steeper.

When welding downwards much practice is required (together with the correct size flame and rod), in order to prevent the molten metal from falling downwards. This method is excellent practice to obtain perfect control of the molten pool.

Double-operator vertical welding

The flames of each welder are adjusted to the neutral condition, both flames being of equal size. To ensure even supply of gas to each pipe the blowpipes can be supplied from the same gas supply. It is possible to use much smaller jets with this method, the combined consumption of which is less than that of a single blowpipe on the same thickness plate. Blowpipes and rods are held at the same angles by each operator, and it is well that a third person should check this when practice runs are being done. To avoid fatigue a sitting position is desirable, while, as for all types of vertical welding, the pipes and tubes should be as light as possible. Angles of blowpipes and rods are shown in Fig. 6.15.

This method has the advantage that plate up to 16 mm thick can be welded without preparation, reducing the gas consumption and filler rod used, and cutting out the time required for preparation. When two operators are welding 12.5 mm plate, the gas used by both is less than 50%

of the total consumption of the blowpipe when welding the same thickness by the downhand rightward method. Owing to the increased speed of welding and the reduced volume of molten metal, there is a reduction in the heating effect, which reduces the effects of expansion and contraction.

Overhead welding

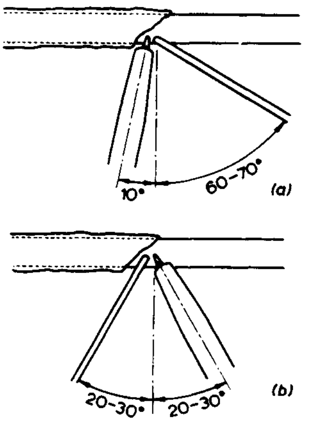
Overhead welding is usually performed by holding the blowpipe at a very steep angle to the plate being welded. The molten pool is entirely controlled by the flame and by surface tension, and holding the flame almost at right angles to the plate enables the pool to be kept in position.

Difficulty is most frequently found in obtaining the correct amount of penetration. This is due to the fact that as sufficient heat to obtain the required penetration is applied, the molten pool becomes more fluid and tends to become uncontrollable. With correct size of flame and rod, however, and practice, this difficulty can be entirely overcome and sound welds made. Care should also be taken that there is no undercutting along the edges of the weld.

A comfortable position and light blowpipe and tubes are essential if the weld is to be made to any fair length, as fatigue of the operator rapidly occurs in this position and precludes the making of a good weld.

The positions of blowpipe and rod for the leftward techniques are shown in Fig. 6.16*a*, while Fig. 6.16*b* shows their relative positions when the rightward method is used. The rightward method is generally favoured, but

Fig. 6.16. (*a*) Leftward overhead welding. The flame is used to position the molten metal. (*b*) Rightward overhead welding. Blowpipe has little motion. Rod moves criss-cross from side to side.



it must again be stressed that considerable practice is required for a welder to become skilled in overhead welding.

Lindewelding

This method was devised by the Linde Co. of the United States for the welding of pipelines (gas and oil), and for this type of work it is very suitable. Its operation is based on the following facts:

1. When steel is heated in the presence of carbon, the carbon will reduce any iron oxide present, by combining with the oxygen and leaving pure iron. The heated surface of the steel then readily absorbs any carbon present.
2. The absorption of carbon by the steel lowers the melting point of the steel (e.g. pure iron melts at 1500 °C, while cast iron with $3\frac{1}{2}\%$ carbon melts at 1130 °C).

In Lindewelding the carbon for the above action is supplied by using a carburizing flame. This deoxidizes any iron oxide present and then the carbon is absorbed by the surface layers, lowering their melting point. By using a special rod, a good sound weld can be made in this way at increased speed. The method is almost exclusively used on pipe work and is performed in the downhand position only.

Block welding

Block welding is a method especially applicable to steel pipes and thick walled tubes in which the weld is carried out to the full depth of the joint in steps. This can more easily be understood by reference to the figure. The first run is laid giving good penetration for as great a length as is convenient, say *AB* (Fig. 6.17).

The second run is now started a little way short of *A* and finished short of *B*, as *CD*. The third run is laid in a similar manner from *E* to *F*, if required, and so on for the full depth of the weld required. We thus have a series of ledges or platforms at the beginning and end of the weld. The welding is now continued with the first run from *B* with full penetration. The second run starts at *D* and has the ledge *BD* deposited before it gets to where the

first run started. Similarly with the third run, which starts at *F*. Upon completing the weld in the case of a pipe, the first run finishes at *A*, the second one at *C* and the third one at *E*, giving a good anchorage on to the previous run.*

Horizontal-vertical fillet welding

In making fillet welds (Fig. 6.18), care must be taken that, in addition to the precautions taken regarding fusion and penetration, the vertical plate is not undercut as in Fig. 6.19*b*, and the weld is not of a weakened section. A lap joint may be regarded as a fillet. No difficulty will be experienced with undercutting, since there is no vertical leg, but care should be taken not to melt the edge of the lapped plate.

The blowpipe and rod must be held at the correct angles. Holding the

flame too high produces undercutting, and the nozzle of the cone should be held rather more towards the lower plate, since there is a greater mass of metal to be heated in this than in the vertical plate (Fig. 6.19*a* and *b*).

Figure 6.20 *a* and *b* show the angles of the blowpipe and rod, the latter being held at a steeper angle than the blowpipe. Fillet welding requires a larger size nozzle than when butt welding the same section plate, owing to the greater amount of metal adjacent to the weld. Because of this, multi-jet blowpipes can be used to great advantage for fillet welding. The single (Fig. 6.19*a*) preparation is used for joints which are subjected to severe loading, while the double V preparation (Fig. 6.19*b*) is used for thick section plate when the welding can be done from both sides. The type of preparation therefore depends entirely on the service conditions, the unprepared joint being quite suitable for most normal work.

All-position rightward welding

This method can be used for vertical, overhead and horizontal–vertical positions, the blowpipe preceding the rod as for downhand welding. For vertical welding the blowpipe is held 10° below the horizontal line (welding upwards) while the rod is held alongside the pipe at 45–60° to the vertical plate. Overhead welding is done similarly. The advantages are similar to those of the downhand position but considerable practice is required to become proficient. See Fig. 6.21.

For the preparation and welding of steel pipes the student should refer to BS 1821, *Class I steel pipelines* and BS 2640, *Class II steel pipelines.*

Note. Phosphorus and sulphur 0.04% max. for all types.

Cast iron welding

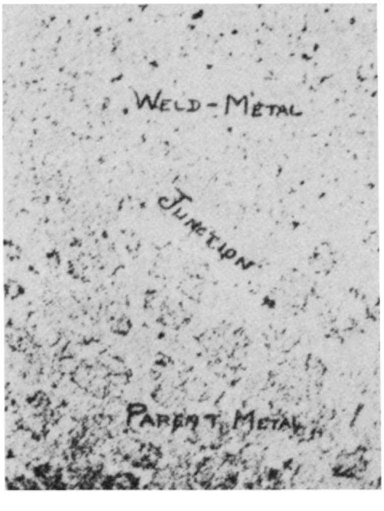
Cast iron, because of its brittleness, presents a different problem in welding from steel. We may consider three types – grey, white and malleable.

The grey cast iron is softer and tougher than the white, which is hard and brittle. The good mechanical properties of grey cast iron are due to the presence of particles of free carbon or graphite, which separate out during slow cooling. When the cooling is rapid, it is impossible for the cementite (iron carbide) to decompose into ferrite and graphite; hence the structure consists of masses of cementite embedded in pearlite, this giving the white variety of cast iron with its hardness and brittleness.

The other constituents of cast iron are silicon, sulphur, manganese and phosphorus. Silicon is very important, because it helps to increase the formation of graphite, and this helps to soften the cast iron. Manganese makes the casting harder and stronger. It has a great affinity for sulphur and, by combining with it, prevents the formation of iron sulphide, which makes the metal hard and brittle. Phosphorus reduces the melting point and increases the fluidity. If present in a greater proportion than 1% it tends to increase the brittleness. Sulphur tends to prevent the formation of graphite and should generally not exceed 0.1%. It may be added to enable the outer layers to have a hard surface (chill casting), while the body of the casting is still kept in the grey state.

The aim of the welder should be always, therefore, to form grey cast iron in the weld (Fig. 6.22).

Fig. 6.22. Oxy-acetylene fusion weld in cast iron. × 100.

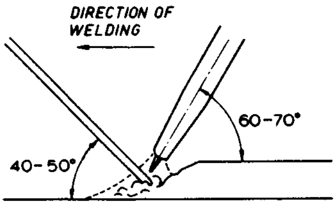


Preparation. The edges are V'd out to 90° on one side only up to 10 mm thickness and from both sides for greater thickness. Pre-heating is essential, because not only does it prevent cracking due to expansion and contraction, but by enabling the weld to cool down slowly, it causes grey cast iron to be formed instead of the hard white unmachinable deposit which would result if the weld cooled off rapidly. Pre-heating may be done by blowpipe, forge or furnace, according to the size of the casting.

Blowpipe, flame, flux and rod. The neutral flame is used, care being taken that there is not the slightest trace of excess oxygen which would cause a weak weld through oxidation, and that the metal is not overheated. The inner cone should be about 3–4 mm away from the molten metal. If it touches the molten metal, hard spots will result. The flux (of alkaline borates) should be of good quality to dissolve the oxide and prevent oxidation, and it will cause a coating of slag to form on the surface of the weld, preventing atmospheric oxidation. Ferro-silicon and super-silicon rods, containing a high percentage of silicon, are the most suitable rods to use.

Technique. The welding operation should be performed on the dull red-hot casting with the rod and blowpipe at the angles shown in Fig. 6.23 and done in the leftward manner. The rod is dipped into the flux at intervals, using only enough flux to remove the oxide. It will be noticed that, as the flux is added, the metal flows more easily and looks brighter, and this gives a good indication as to when flux is required. The excessive use of flux causes blowholes and a weak weld. The rod should be pressed down well into the weld, removing a good percentage of the slag and oxide. Very little motion of the blowpipe is required and the rod should not be stirred round continuously, as this means the formation of more slag with more danger of entrapping it in the weld. Cast-iron welds made by beginners often have brittle parts along the edges, due to their not getting under the oxide and floating it to the top.

Fig. 6.23. Cast iron welding.



After treatment. The slag and oxide on the surface of the finished weld can be removed by scraping and brushing with a wire brush, but the weld should not be hammered. The casting is then allowed to cool off very slowly, either in the furnace or fire, or if it has been pre-heated with the flame, it can be put in a heap of lime, ashes or coke, to cool. Rapid cooling will result in a hard weld with possibly cracking or distortion.

Malleable cast iron welding

This is unsuitable for welding with cast-iron rods because of its structure. If attempted it invariably results in hard, brittle welds having no strength. The best method of welding is with the use of bronze rods, and is described below.

Braze welding and bronze welding

Braze welding is the general term applied to the process in which the metal filler wire or strip has a lower melting point than that of the parent metal, using a technique similar to that used in fusion welding, except that the parent metal is not melted nor is capillary action involved as in brazing. When the filler metal is made of a copper-rich alloy the process is referred to as bronze welding.

By the use of bronze filler wires such as those given in the table on p. 290, a sound weld can be made in steel, wrought iron, cast iron and copper and between dissimilar metals such as steel and copper, at a lower temperature than that usually employed in fusion welding. The bronze filler metal, which has a lower melting point than the parent metal, is melted at the joint so as to flow and 'wet' the surfaces of the joint to form a sound

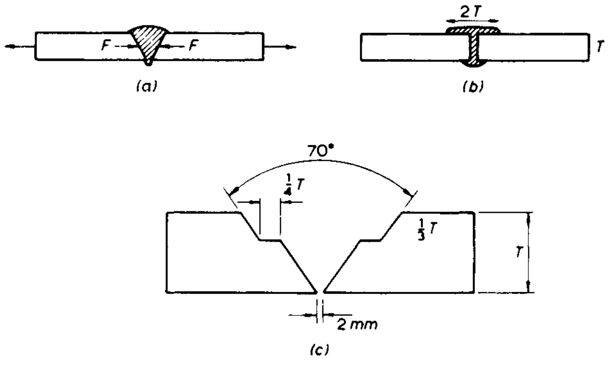


Fig. 6.24. When specimen (*a*) is subjected to a tensile pull as shown the faces *F* of the joint are partly in shear. (*c*) 'Shear V' preparation.

bond without fusion of the parent metal. There is less thermal disturbance than with fusion welding due to the lower temperatures involved and the process is simple and relatively cheap to perform. Unlike capillary brazing (see pp. 317–19) the strength of the joint is not solely dependent upon the areas of the surfaces involved in the joint but rather upon the tensile strength of the filler metal. A bronze weld has relatively great strength in shear, and joints are often designed to make use of this (Fig. 6.24*a*, *b* and *c*).

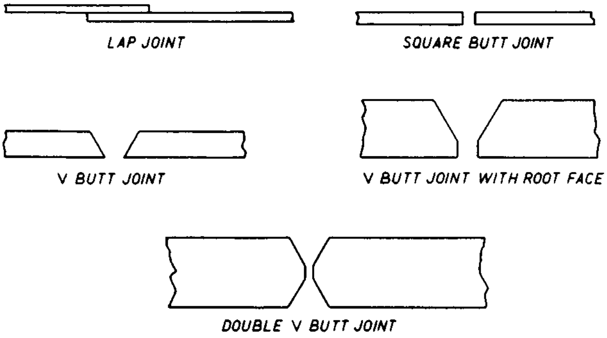
The final strength of the welded joint depends upon the bond between filler metal and parent metal so that thorough cleanliness of the joints and immediate surroundings is essential to ensure that the molten filler metal should flow over the areas and 'wet' them completely without excessive penetration of the parent metal, and there should be freedom from porosity. Care, therefore, should be taken to avoid excessive overheating. Figs. 6.25 and 6.26 show various joint designs for plate and tube.

If bronze filler wires are used on alloys such as brasses and bronzes the melting points of wire and parent metal are so nearly equal that the result is a fusion weld.

General method of preparation for bronze welding. All impurities such as scale, oxide, grease, etc., should be removed, as these would prevent the bronze wetting the parent metal. The metal should be well cleaned on both upper and lower faces for at least 6 mm on each side of the joint, so that the bronze can overlap the sides of the joint, running through and under on the lower face.

Bronze welding is unlike brazing in that the heat must be kept as local as possible by using a small flame and welding quickly. The bronze must flow in front of the flame for a short distance only, wetting the surface, and by having sufficient control over the molten bronze, welding may be done in

Fig. 6.25. Typical joint designs for bronze welding (sheet and plate).



the overhead position. Too much heat prevents satisfactory wetting. We will now consider the bronze welding of special metals using a flux of a mixture of alkaline fluoride and borax, but bronze filler rods are also supplied flux-coated.

Cast iron

Bevel the edges to a 90° V, round off the sharp edges of the V, and clean the casting well. Pre-heating may be dispensed with unless the casting is of complicated shape, and the welding may often be done without dismantling the work. If pre-heating is necessary it should be heated to

British Standards designations, compositions and recommended usage of filler alloys for bronze welding

450 °C, and on completion cooling should be as slow as possible as in the fusion welding of cast iron (Fig. 6.27).

Blowpipe, flame and rod. The blowpipe nozzle may be about two sizes smaller than for the same thickness steel plate, and the flame is adjusted so as to give a slight excess of oxygen. If a second deposit is to be run over the first, the flame is adjusted to a more oxidizing condition still for the subsequent runs, the inner cone being usually only about $\frac{3}{4}$ of its neutral length. The best flame condition can easily be found by trial. Suitable filler

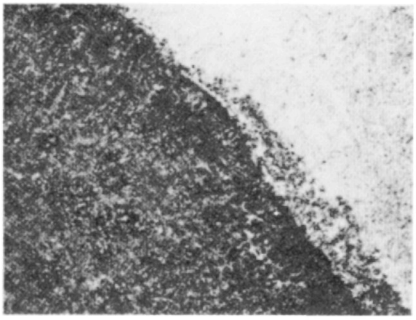
Fig. 6.27. Bronze weld in cast iron.



alloys are given in the table, those containing nickel giving greater strength, the bronze flux being of the borax type.

Technique. The leftward method is used with the rod and blowpipe held as in Fig. 6.28, the inner cone being held well away from the molten metal. The rod is wiped on the edges of the cast iron and the bronze wets the surface. It is sometimes advisable to tilt the work so that the welding is done uphill, as shown in Fig. 6.28. This gives better control. Do not get the work too hot.

Vertical bronze welding of cast iron can be done by the two-operator method, and often results in saving of time, gas and rods and reduces the risk of cracking and distortion.

The edges are prepared with a double 90° V and thoroughly cleaned for 12 mm on each side of the edges. The blowpipes are held at the angle shown in Fig. 6.29*a*. Blowpipe and rod are given a side to side motion, as indicated in Fig. 6.29*b* as the weld proceeds upwards, so as to tin the surfaces.

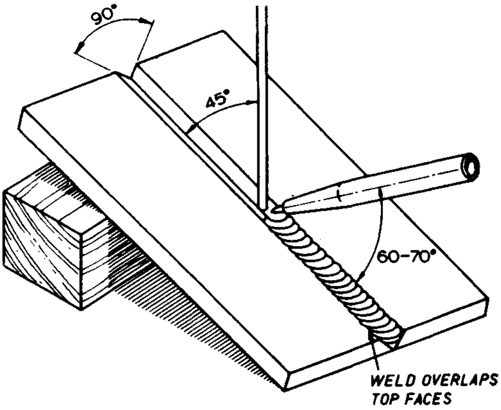
Malleable cast iron

The bronze welding of malleable castings may be stated to be the only way to ensure any degree of success in welding them. Both types (blackheart and whiteheart) can be welded satisfactorily in this way, since the heat of the process does not materially alter the structure. The method is the same as for cast iron, using nickel bronze rods (C5) and a borax-type flux.

Steel

In cases where excessive distortion must be avoided, or where thin sections are to be joined to thick ones, the bronze welding of steel is often

Fig. 6.28. Bronze welding cast iron.



used, the technique being similar to that for cast iron, except, of course, that no pre-heating is necessary.

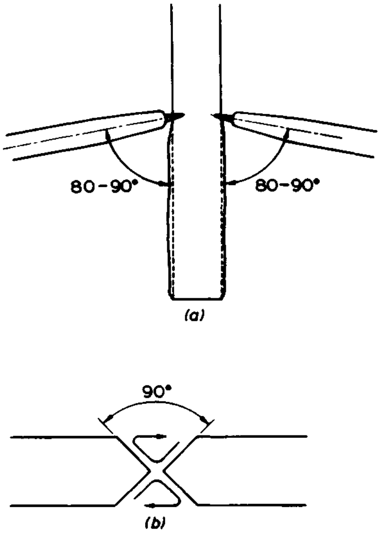
Galvanized iron

This can be easily bronze welded, and will result in a strong corrosion-resisting joint, with no damage to the zinc coating. If fusion welding is used, the heat of the process would of course burn the zinc (or galvanizing) off the joint and the joint would then not resist corrosion.

Preparation, flame and rod. For galvanized sheet welding, the edges of the joint are tack welded or held in a jig and smeared with a silver–copper flux. Thicker plates and galvanized pipes are bevelled 60–80° and tacked to position them. The smallest possible nozzle should be used (for the sheet thickness) and the flame adjusted to be slightly oxidizing. Suitable filler alloys are given in the table (p. 290) as for steel.

Technique. No side to side motion of the blowpipes is given, the flame being directed on to the rod, so as to avoid overheating the parent sheet. The rod is stroked on the edges of the joint so as to wet them. Excessive flux *must* be washed off with hot water.

Fig. 6.29. (*a*) Two-operator vertical bronze welding of cast iron. (*b*) Showing motion of pipe and rod.

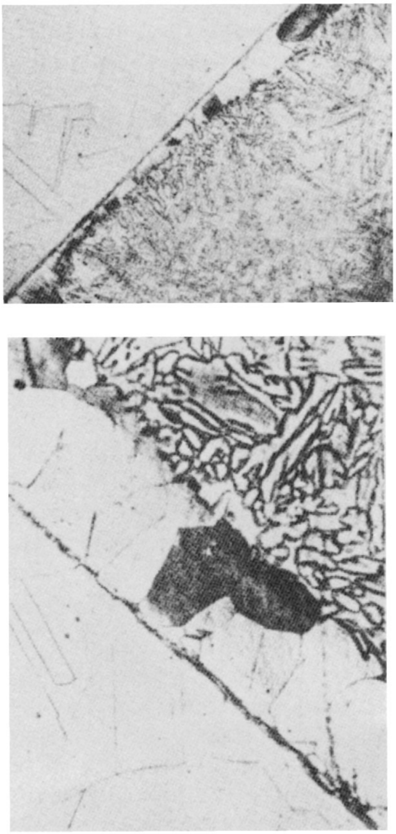


Copper

Tough pitch copper can be readily bronze welded owing to the much lower temperature of the process compared with fusion welding (Fig. 6.30).

Preparation, flame and rod. Preparation is similar to that for cast iron. Copper tubes can be bell mouthed (Fig. 6.31). Special joints are available for multiple branches. The blowpipe nozzle should be small and will depend on the size of the work or the diameter of the pipe to be welded, and should be chosen so that the bronze flows freely but no overheating occurs. The flame should be slightly oxidizing, and if a second run is made, it should be adjusted slightly to be more oxidizing still (inner cone about $\frac{3}{4}$ of its normal neutral length). Suitable filler alloys are given in the table (p. 290) and are used with a bronze-base flux.

Fig. 6.30. Bronze weld in copper. × 250.



Technique. The method is similar to that for cast iron, and the final difference between the bronze-welded and brazed joint is that the former has the usual wavy appearance of the oxy-acetylene weld, while the latter has a smooth appearance, due to the larger area over which the heat was applied. The bronze joint is, of course, much stronger than the brazed one.

Brasses and zinc-containing bronzes

Since the filler rod now melts at approximately the same temperature as the parent metal, this may now be called fusion welding. When these alloys are heated to melting point, the zinc is oxidized, with copious evolution of fumes of zinc oxide, and if this continued, the weld would be full of bubble holes and weak (Fig. 6.32). This can be prevented by using an oxidizing flame, so as to form a layer of zinc oxide over the molten metal, and thus prevent further formation of zinc oxide and vaporization.

Preparation. The edges of the faces of the joint are cleaned and prepared as usual, sheets above 3.2 mm thickness being V'd to 90°. Flux can be applied by making it into a paste, or by dipping the rod into it in the usual manner, or a flux-coated rod can be used.

Flame and rod. Suitable filler alloys are given in the table (p. 290), while a brass rod is used for brass welding, the colour of the weld then being similar to that of the parent metal. Owing to the greater heat conductivity, a larger size jet is required than for the same thickness of steel plate. The flame is adjusted to be oxidizing, as for bronze welding cast iron, and the exact flame condition is best found by trial as follows. A small test piece of the brass or bronze to be welded is heated with a neutral flame and gives off copious fumes of zinc oxide when molten. The acetylene is now cut down until no more fumes are given off. If any blowholes are seen in the metal on solidifying, the acetylene should be reduced slightly further. The inner cone will now be about half its normal neutral length. Too

Fig. 6.31

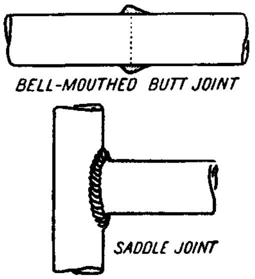


Fig. 6.32. (*a*) Unsatisfactory brass weld made with neutral flame, Unetched × 2.5. (*b*) Brass weld made with insufficient excess of oxygen. Unetched. (*c*) Correct brass weld made with adequate excess of oxygen. Unetched. × 2.5.

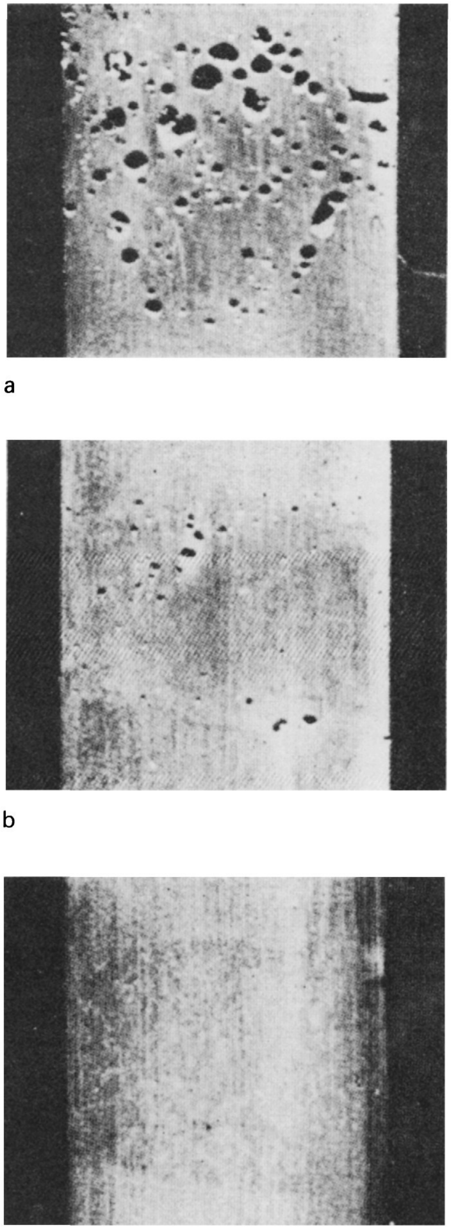

much oxygen should be avoided, as it will form a thick layer of zinc oxide over the metal and make the filler rod less fluid.

The weld is formed in the 'as cast' condition, and hammering improves its strength. Where 60/40 brass rods have been used the weld should be hammered while hot, while if 70/30 rods have been used the weld should be hammered cold and finally annealed from dull red heat.

Tin bronze

Tin bronze cannot be welded using an oxidizing flame. Special rods and fluxes are available, however, with which good welds can be made. Urgent repairs may be safely carried out using a *neutral* flame and a silicon–bronze rod with borax-type flux.

Gilding metal

For the weld to be satisfactory on completion, the weld metal must have the same colour as the parent metal. Special rods of various compositions are available, so that the colours will 'match'.

Aluminium bronze

Aluminium bronze can be welded using a filler rod of approximately 90% copper, 10% aluminium (C13, BS 2901 Pt 3), melting point 1040 °C, a rod also suitable for welding copper, manganese bronze and alloy steels where resistance to shock, fatigue and sea-water corrosion is required. The aluminium bronze flux (melting point 940 °C) can be mixed with water to form a paste if required.

Preparation. The edges of the joint should be thoroughly cleaned by filing or wire brushing to remove the oxide film which is difficult to dissolve.

Up to 4.8 mm thickness no preparation is required – just a butt joint with gap. Above 4.8 mm the usual V preparation is required and a double V above 16 mm thick. Sheets should not be clamped for welding, as this tends to cause the weld to crack, they must be allowed to contract freely on cooling, and it is advisable to weld a seam continuously and not make starts in various places.

Flame and rod. A neutral flame is usually used – any excess of acetylene tends to produce hydrogen with porosity of the weld, while excess oxygen causes oxidation. Flame size should be carefully chosen according to the thickness of the plate – too small a flame causes the weld metal to solidify too quickly while there is a danger of burning through with too large a flame.

The filler rod should be a little thicker (0.8 mm) than the sheet to be welded to avoid overheating, and it should be added quickly to give complete penetration without deep fusion.

Technique. The leftward method is used with a steep blowpipe angle (80°) to start the weld, this being reduced to 60–70° as welding progresses. The parent metal should be well pre-heated prior to starting welding and during welding a large area should be kept hot to avoid cracks. The rod should be used with a scraping motion to clean the molten pool and remove any entrapped gas.

In welding the single-constituent (or α phase) aluminium bronze, i.e. 5–7% Al, 93% Cu, the weld metal should be deposited in a single run or at most two runs to avoid intergranular cracks. Since the metal is hot short in the range 500–700 °C it should cool quickly through the range, and should not be peened. Cold peening is sometimes an advantage. The two-constituent (α and β) or duplex aluminium bronzes contain 10% aluminium. They have a wide application, are not as prone to porosity, and are easier to weld than the 7% Al type, and also their hot short range is smaller.

After treatment. Stresses can be relieved by heat treating at low temperature, and any required heat treatment can be carried out as required after welding.

Copper welding

Tough pitch copper (that containing copper oxide) is difficult to weld, and so much depends on the operator's skill that it is advisable to specify deoxidized copper for all work in which welding is to be used as the method of jointing. Welds made on tough pitch copper often crack along the edge of the weld if they are bent (Fig. 6.33*a*), showing that the weld is unsound due to the presence of oxide, often along the lines of fusion. A *good* copper weld (Fig. 6.33*b*), on the other hand, can be bent through 180° without cracking and can be hammered and twisted without breaking. This type of copper weld is strong and sound, free from corrosion effects, and is eminently satisfactory as a method of jointing.

Preparation. The surfaces are thoroughly cleaned and the edges are prepared according to the thickness, as shown in Fig. 6.34. In flanging thin sheet the height of the flange is about twice the plate thickness and the flanges are bent at right angles. Copper has a high coefficient of expansion, and it is necessary therefore to set the plates diverging at the rate of 3–4 mm per 100 mm run, because they come together so much on being welded. Since copper is weak at high temperatures, the weld should be well supported if possible and an asbestos sheet between the weld and the backing strip of steel prevents loss of heat.

Tacking to preserve alignment is not advised owing to the weakness of the copper tacks when hot. When welding long seams, tapered spacing clamps or jigs should be used to ensure correct spacing of the joint, care

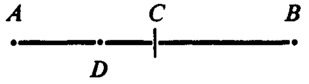
being taken that these do not put sufficient pressure on the edges to indent them when hot. A very satisfactory method of procedure is to place a clamp *C* at the centre of the seam and commence welding at a point say about one-third along the seam.



Welding is performed from *D* to *B* and then from *D* to *A*.

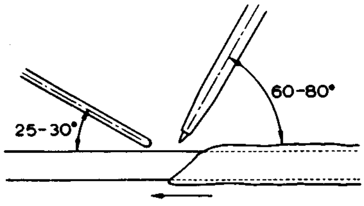
Because of the high conductivity of copper it is essential to pre-heat the surface, so as to avoid the heat being taken from the weld too rapidly. If the surface is large or the metal thick, two blowpipes must be used, one being used for pre-heating. When welding pipes they may be flanged or plain butt welded, while T joints can be made as saddles.

Blowpipe, flame and rod. A larger nozzle than for the same thickness of steel should be used and the flame adjusted to be neutral or very slightly carbonizing. Too much oxygen will cause the formation of copper oxide and the weld will be brittle. Too much acetylene will cause steam to form, giving a porous weld, therefore close the acetylene valve until the white feathery plume has almost disappeared. The welding rod should be of the deoxidized type, and many alloy rods, containing deoxidizers and other elements such as silver to increase the fluidity, are now available and give excellent results.

The weld may be made without flux, or a flux of the borax type used. Proprietary fluxes containing additional chemicals greatly help the welding operation and make it easier.

Technique. The blowpipe is held at a fairly steep angle, as shown in Fig. 6.35, to conserve the heat as much as possible. Great care must be taken to keep the tip of the inner cone 6–9 mm away from the molten metal, since the weld is then in an envelope of reducing gases, which prevent oxidation. The weld proceeds in the leftward manner, with a slight sideways motion of the blowpipe. Avoid agitating the molten metal, and do not remove the rod from the flame but keep it in the molten pool. Copper may

Fig. 6.35. Copper welding.



also be welded by the rightward method, which may be used when the filler rod is not particularly fluid. The technique is similar to that for rightward welding of mild steel, with the flame adjusted as for leftward welding of copper.

Welding can also be performed in the vertical position by either single- or double-operator method, the latter giving increased welding speed.

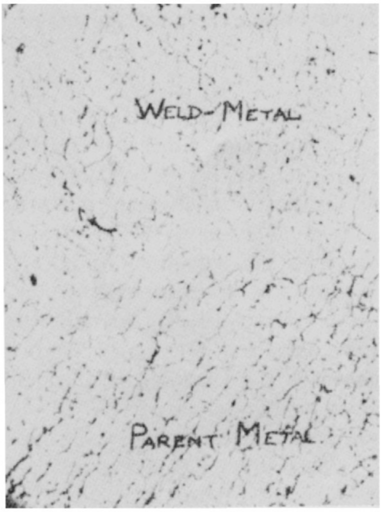
After treatment. Light peening, performed while the weld is still hot, increases the strength of the weld. The effect of cold hammering is to consolidate the metal, but whether or not it should be done depends on the type of weld and in general is not advised. Annealing, if required on small articles, can be carried out by heating to 600–650 °C.

Aluminium welding

The welding of aluminium, either pure or alloyed, presents no difficulty (Fig. 6.36) provided the operator understands the problems which must be overcome and the technique employed.

The oxide of aluminium (alumina Al_2O_3), which is always present as a surface film and which is formed when aluminium is heated, has a very high melting point, much higher than that of aluminium, and if it is not removed it would become distributed throughout the weld, resulting in weakness and brittleness. A good flux, melting point 570 °C, is necessary to dissolve this oxide and to prevent its formation.

Fig. 6.36. Oxy-acetylene weld in aluminium. × 45.



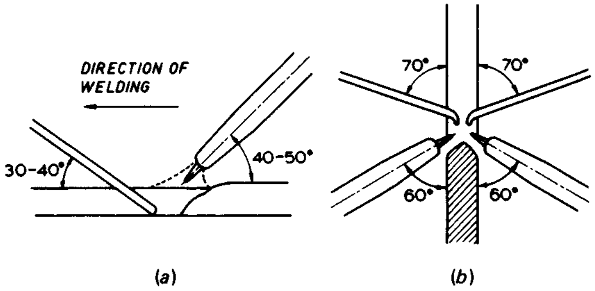
Aluminium and its alloys

Preparation. The work should be cleaned of grease and brushed with a wire brush. Sheets below 1 mm thickness can be turned up at right angles (as for mild steel) and the weld made without a filler rod. Over 3.2 mm thick the edges should have a 90° V and over 6 mm thick a double 90° V. Tubes may be bevelled if thick or simply butted with a gap between them. It is advisable always to support the work with backing strips of asbestos or other material, to prevent collapse when welding. Aluminium, when near its melting point, is extremely weak, and much trouble can be avoided by seeing that no collapsing can occur during the welding operation.

Blowpipe, flame, flux and rod. The flame is adjusted to have a very slight excess of acetylene and then adjusted to neutral, and the rod of pure aluminium or 5% silicon–aluminium alloy should be a little thicker than the section to be welded. A good aluminium flux must be used and should be applied to the rod as a varnish coat, by heating the end of the rod, dipping it in the flux and letting the tuft, which adheres to the rod, run over the surface for about 150 mm of its length. This ensures an even supply. Too much flux is detrimental to the weld.

Technique. The angles of the blowpipe and rod are shown in Fig. 6.37 (a slightly larger angle between the blowpipe and rod than for mild steel), and the welding proceeds in the leftward manner, keeping the inner cone well above the molten pool. The work may be tacked at about 150 mm intervals to preserve alignment, or else due allowance made for the joint coming in as welded, like mild steel. As the weld progresses and the metal becomes

Fig. 6.37. (*a*) Aluminium flat welding. Rightward technique may also be employed using approximately the same angles of blowpipe and rod. (*b*) Aluminium welding by the double-operator method.



hotter, the rate of welding increases, and it is usual to reduce the angle between blowpipe and weld somewhat to prevent melting a hole in the weld. Learners are afraid of applying sufficient heat to the joint as a rule, because they find it difficult to tell exactly when the metal is molten, since it does not change colour and is not very fluid. When they do apply enough heat, owing to the above difficulty, the blowpipe is played on one spot for too long a period and a hole is the result.

If the rightward technique is used the blowpipe angle is 45° and the rod angle 30–40°. Distortion may be reduced when welding sheets, and the flame anneals the deposited metal.

The two-operator vertical method may be employed (as for cast iron) on sheets above 6 mm thickness, the angle of the blowpipes being 50–60° and the rods 70–80°. This method gives a great increase in welding speed (Fig. 6.37)

After treatment. All the corrosive flux must be removed first by washing and scrubbing in hot soapy water. This can be followed by dipping the article in a 5% nitric acid solution followed by a washing again in hot water.

Where it is not possible to get at the parts for scrubbing, such as in tanks, etc., the following method of removal is suitable. Great care, however, should be taken when using the hydrofluoric acid as it is dangerous, and rubber gloves should be worn, together with a face mask.

A solution is made up as follows in a heavy duty polythene container.

Nitric acid – 100 g to 1 litre water.
Hydrofluoric acid – 6 g to 1 litre water.

The nitric acid is added to the water first, followed by the hydrofluoric acid.

Articles immersed in this solution for about ten minutes will have all the flux removed from them, and will have a uniformly etched surface. They should then be rinsed in cold water followed by a hot rinse, the time of the latter not exceeding three minutes, otherwise staining may occur.

Hammering of the completed weld greatly improves and consolidates the structure of the weld metal, and increases its strength, since the deposited metal is originally in the 'as cast' condition and is coarse grained and weak. Annealing may also be performed if required.

Aluminium alloy castings and sheets

The process for the welding of castings is very similar to that for the welding of sheet aluminium. See Volume 1 for explanation of alloy coding letters.

Preparation. The work is prepared by V'ing if the section is thicker than 3 mm, and the joint is thoroughly cleaned of grease and impurities. Castings such as aluminium crank-cases are usually greasy and oily (if they have been in service), the oil saturating into any crack or break which may have occurred. If the work is not to be pre-heated, this oil *must* be removed. It may be washed first in petrol, then in a 10% caustic soda solution, and this followed by a 10% nitric acid or sulphuric acid solution. A final washing in hot water should result in a clean casting. In normal cases in which pre-heating is to be done, filing and a wire brush will produce a clean enough joint, since the pre-heating will burn off the remainder.

Aluminium alloys. Recommended filler rods

Alloys	Composition % (remainder aluminium)	Filler rod (old designation in brackets)
Casting alloys BS 1490		
LM2	0.7–2.5 Cu, 9–11.5 Si	4047A, 10–12% Si (NG2)
LM4	2–4 Cu, 4–6 Si	4047A or 4043A, 4.5–6% Si (NG2 or NG21)
LM5	3–6 Mg	5356, 4.6–5.5 Mg (NG6)
LM6	10–13 Si, 0.5 Mn	4043, 415–6.0 Si (NG21)
LM9	10–13 Si, 0.3–0.7 Mn	4043 or 4047 (NG21 or NG2)
LM18	4.5–6 Si	4043 (NG21)
LM20	10–13 Si, 0.4 Cu	4047 (NG2)
Wrought alloys BS 1470–1477		
1080A	99.8 Al	1080A (G1B)
1050A	99.5 Al	1080A (G1C)
3103 (N3)	1–1.5 Mn	3103 (NG3)
6063 (H9)	0.4–0.9 Mg, 0.3–0.7 Mn	4043 or 5056A (NG21 or NG6)
061 (H20)	0.15 C 0.4 Cu, 0.8–1.2 Mg, 0.4–0.8 Si, 0.2–0.8 Mn, 0.15–0.35 Cr	4043 or 5056A (NG21 or NG6)
6082 (H30)	0.5–1.2 Mg, 0.7–1.3 Si, 0.4–1.0 Mn	4043 or 5056A (NG21 or NG6)

If the casting is large or complicated, pre-heating should be done as for cast iron.* In any case it is advantageous to heat the work well with the blowpipe flame before commencing the weld.

---

* Large complicated castings can be pre-heated to about 400 °C, smaller castings to 300–350 °C and small castings to 250–300 °C. No visible change in the appearance of the aluminium occurs at these temperatures.

Blowpipe, flame, rod and flux. The blowpipe is adjusted as for pure aluminium and a similar flame used. The welding rod should preferably be of the same composition as the alloy being welded (see table on p. 290) but for general use a 5% silicon–aluminium rod is very satisfactory. This type of rod has strength, ductility, low shrinkage, and is reasonably fluid. A 10% silicon–aluminium rod is used for high silicon castings, while 5% copper–aluminium rods are used for the alloys containing copper, such as Y alloy, and are very useful in automobile and aircraft industries. The deposit from this type of rod is harder than from the other types.

When welding the Al–Mg alloys the oxide film consists of both aluminium and magnesium oxide making the fluxing more difficult so that as the magnesium proportion increases welding may become more difficult. Alloys containing more than 2½% Mg, e.g. 5154A (N5) and 5183 (N8) are difficult to weld and require considerable experience as do the high strength alloys 6061 (H15) and 6082 (H30). The inert gas arc processes are to be preferred for welding these alloys.

Since there is also a loss of Mg in the welding process note that the filler rod recommended has a greater Mg content than the parent plate. The flux used is similar to that for pure aluminium and its removal must be carried out in the same way.

Technique. The welding is carried out as for aluminium sheet, and the cooling of the casting after welding must be gradual.*

After-treatment. After welding, the metal is in the 'as cast' condition and is weaker than the surrounding areas of parent metal, and the structure of the deposited metal may be improved by hammering. The area near the welded zone, however, is annealed during the welding process and failure thus often tends to occur in the area alongside the weld, and not in the weld itself. In the case of heat-treatable alloys, the welded zone can be given back much of its strength by first lightly hammering the weld itself and then heat-treating the whole of the work.

For this to be quite successful it is essential that the weld should be of the same composition as the parent metal. If oxidation has occurred, however, this will result in a weld metal whose structure will differ from that of the parent metal and the weld will not respond to heat treatment. Since many of this type of alloy are 'hot short', cracking may occur as a result of the welding process.

---

* When repairing cracked castings, any impurities which appear in the molten pool should be floated to the top, using excess flux if necessary.

If sheets are anodized, the welding disturbs the area and changes its appearance. Avoidance of overheating, localizing the heat as much as possible, and hammering, will reduce this disturbance to a minimum, but heat treatment will make the weld most inconspicuous.

Welding of nickel and nickel alloys

The alloys include MONEL® (nickel–copper) and INCONEL® (nickel–chromium) alloys and modifications of these constituents to give variations in properties.

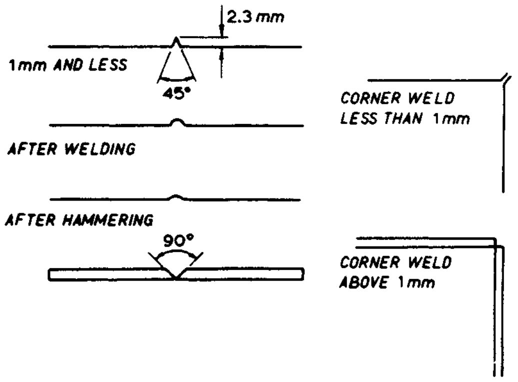
Oxy-acetylene welding is used only for welding Nickel 200 alloy, certain MONEL® alloys, INCO® and INCONEL® alloys. Welding of nickel–chromium–cobalt alloys (NIMONIC® alloy) is not usually performed. (Consult the manufacturers for up to date details.)

Preparation. Sheets of thinner than 1 mm can be bent up through an angle of about 75°, as shown in Fig. 6.38, and the edges melted together. The ridge formed by welding can then be hammered flat. Sheets thicker than 1 mm are bevelled with the usual 90° V and butted together. For corner welds on sheet less than 1 mm the corners are flanged as shown, while for thicker plate the weld is treated as an open corner joint (see Fig. 6.38). Castings should be treated as for cast iron.

In tube welding, preparation should be an 80° V with no root gap.

Blowpipe, flame, flux and rod, High-purity acetylene as supplied from DA cylinders is required, and in general the blowpipe nozzle size is the same as that for the same thickness mild steel. For nickel 200 a size larger can be used. No flux is required for nickel 200 and for Incoloy DS the use of flux is

Fig. 6.38. Preparation of plates.



optional and special fluxes are available for the other alloys. Flux containing boron should not be used with alloys containing chromium as it tends to cause hot cracking in the weld. The joint is tacked in position without flux. The flux is made into a thin paste and painted onto both sides of the joint and the filler rod and allowed to dry before welding. Fused flux remaining should be removed by wire brushing and unfused flux with hot water. Flux remaining (after welding the nickel chromium alloys) can be removed by treatment with a solution of equal parts of nitric acid and water for 15–30 minutes followed by washing with water. Flux removal is important when high-temperature applications are involved, as the flux may react with the metal.

Technique. Leftward technique is used. Weaving and puddling of the molten pool should be avoided as agitation of the pool causes porosity due to the absorption of gases by the high-nickel alloys, and the filler rod should be kept within the protective envelope of the flame to prevent oxidation. Keep the flame tip above the pool but for MONEL® alloy K500 let it just touch the pool. Nickel 200 melts sluggishly. INCONEL® alloy 600, NIMONIC® alloy 75 and the BRIGHTRAY® alloys are more fluid while MONEL® alloy 400 and INCOLOY® DS alloy flow easily. A slightly carburizing soft flame (excess acetylene) should be used for the nickel and nickel–copper alloys, whilst for the chromium-containing alloys the flame should be a little more carburizing.

There are no pronounced ripples on the weld surface. They should be smooth without roughness, burning or signs or porosity.

Examples of filler metals

Material	
Nickel alloys 200, 201	Nickel filler metal 61
MONEL® alloys 400, R405, K500	MONEL® filler metal 60
INCONEL® alloy 600	INCONEL® filler metal 62
INCONEL® alloys 600, 601	INCONEL® filler metal 82
INCOLOY® alloys 800, 800HT	
INCO® alloy 330	
INCOLOY® DS	N/C (nickel–chromium) filler metal

When welding tube with 80° feather edge preparation and no root gap, the first run is made with no filler rod, the edges being well fused together to give an even penetration bead, followed by filler runs. If the work is rotatable, welding in the two o'clock position gives good metal control. If the joint is fixed, vertical runs should be made first downwards followed by a run upwards.

Nickel clad steel*

This steel is produced by the hot rolling of pure nickel sheet on to steel plate, the two surfaces uniting to form a permanent bond. It gives a material having the advantage of nickel, but at much less cost than the solid nickel plate. It can be successfully welded by the oxy-acetylene process.

Preparation. The bevelled 90° butt joint is the best type. For fillet welds it is usual to remove (by grinding) the nickel cladding on the one side of the joint, as shown in Fig. 6.39, so as to ensure a good bond of steel to steel.

Technique. The weld is made on the steel side first, using a mild steel rod and the same technique as for mild steel. The nickel side is then welded, using a nickel rod and a slightly reducing flame as for welding monel and nickel. The penetration should be such that the nickel penetrates and welds itself into the steel weld.

Stainless steels

Stainless steels of the martensitic and austenitic class can be welded by the oxy-acetylene process.

Preparation. Thin gauges may be flanged at 90° as for mild steel sheet and the edges fused together. Thicker sections are prepared with the usual 90° V and the surfaces cleaned of all impurities. The coefficient of expansion of the 18/8 austenitic steels is about 50% greater than that of mild steel, and consequently the sheets should be set diverging much more than for mild

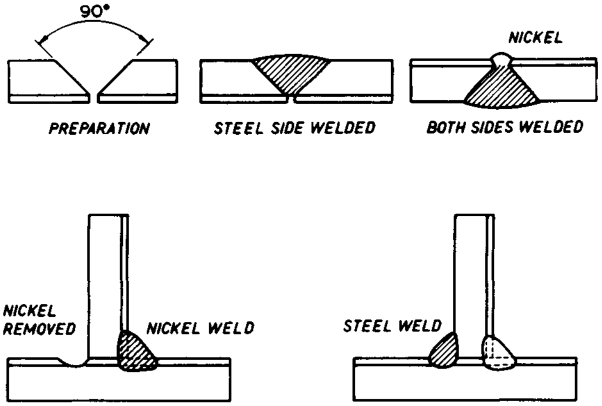


Fig. 6.39. Double fillet weld. Nickel clad steel.

---

* Also stainless clad steel

steel to allow for them coming together during welding. An alternative method is to tack the weld at both ends first, and then for sheets thinner than 1 mm tack at 25 mm intervals, while for thicker sheets the tacks can be at 50 mm intervals. Cooling clamps are advised for the austenitic steels. The thermal conductivity is less than for mild steel, and thus the heat remains more localized. Unless care is taken, therefore, the beginner tends to penetrate the sheet when welding thin gauges.

Flame. The flame should be very slightly carburizing (excess acetylene), there being the smallest trace of a white plume around the inner cone. The flame should be checked from time to time to make sure that it is in this condition, since any excess oxygen is fatal to a good weld, producing porosity, while too great an excess of acetylene causes a brittle weld.

Rod and flux. The welding rod must be of the same composition as the steel being welded, the two types normally used being the 18/8 class, and one having a higher nickel and chromium content and suitable for welding steels up to a 25/12 chrome–nickel content. Since there is considerable variety in the amounts of the various elements added to stainless steels to improve their physical properties, such as molybdenum and tungsten in addition to titanium or niobium, it is essential that the analysis of the parent metal be known so that a suitable rod can be chosen. The steel makers and electrode makers will always co-operate in this matter. The rod should be of the same gauge or slightly thicker than the sheet being welded. No flux is necessary, but if difficulty is experienced with some steels in penetration, a special flux prepared for these steels should be used, and can be applied as a paste mixed with water.

Technique. Welding is performed in the leftward manner, and the flame is played over a larger area than usual because of the low thermal conductivity. This lessens the risk of melting a hole in the sheet. The tip of the inner cone is kept very close to the surface of the molten pool and the welding performed exactly as for the leftward welding of mild steel. No puddling should be done and the least possible amount of blowpipe motion used.

After treatment. Martensitic stainless steels should be heated to 700 to 800°C and then left to air cool. The non-stabilized steels require heat treatment after welding if they are to encounter corrosive conditions, otherwise no heat treatment is necessary. The weld decay-proof stabilized steels and those with a very low carbon content require no heat treatment after welding.

The original silver-like surface can be restored to stainless steels which have scaled or oxidized due to heat by immersing in a bath made up as follows: sulphuric acid 8%, hydrochloric acid 6%, nitric acid 1%, water 85%. The temperature should be 65 °C and the steel should be left in for 10 to 15 minutes, and then immersed for 15 minutes or until clean in a bath of 10% nitric acid, 90% water, at 25 °C.

Other baths made up with special proprietary chemicals with trade names will give a brighter surface. These chemicals are obtainable from the makers of the steel.

Stainless iron

The welding of stainless iron results in a brittle region adjacent to the weld. This brittleness cannot be completely removed by heat treatment, and thus the welding of stainless iron cannot be regarded as completely satisfactory. When, however, it has to be welded the welding should be done as for stainless steel, using a rod specially produced for this type of iron.

Hard surfacing and stelliting

Surfaces of intense hardness can be applied to steel, steel alloys, cast iron or monel metal, by means of the oxy-acetylene flame. The surfaces are hard and have intense resistance to wear and corrosion. By depositing a surface on a more ductile metal we have an excellent combination. Metals easily hardfaced are low- and medium-carbon steels, steels above 0.4% C, low-alloy steels, nickel, nickel–copper alloys, chrome-nickel and nobium bearing stainless steels (not titanium bearing nor free machining). Those metals faced with difficulty include cast iron, straight chromium stainless steels, tool and die steels and water-, air- and oil-hardening steels while copper, brass and other low melting point alloys are not suitable for hard surfacing. Hard surfaces may be deposited either on new parts so that they will have increased resistance to wear at reduced cost, or on old parts which may be worn, thus renewing their usefulness. In addition, non-ferrous surfaces, such as bronze or stellite, may be deposited and are described under their respective headings.

The surfaces deposited may be hard and/or wear and corrosion resisting. It is usual in the case of hard surfaces for the metal to be machinable as deposited, but to be capable of being hardened by quenching or by work hardening, e.g. 12/14% Mn (see table of rods available on p. 323).

We may divide the methods as follows:

(1) Building up worn parts with a deposit similar to that of the parent metal. This process is very widely used, being cheap and economical, and is used for building up, for example, gear wheels, shafts, key splines, etc.

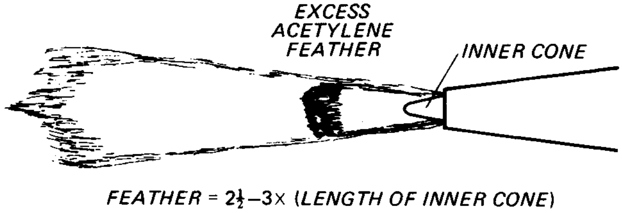
The technique employed is similar to that for mild steel, using a neutral flame and the leftward method. The deposit should be laid a little at a time and the usual precautions taken for expansion and distortion. Large parts should be pre-heated and allowed to cool out very slowly, and there are no difficulties in the application.

(2) Building up surfaces with rods containing, for example, carbon, manganese, chromium or silicon to give surfaces which have the required degree of hardness or resistance to wear and corrosion. These surfaces differ in composition from that of the parent metal, and as a result the fusion method of depositing cannot be used, since the surface deposit would become alloyed with the base metal and its hardness or wear-resisting properties would be thus greatly reduced.

(3) Hard facing with tungsten carbide. The rods consist of a steel tube containing fused granules of tungsten carbide HV 1800 in a matrix of chromium iron HV 850. Various grades are available with granules of different mesh size. Large granules embedded in the steel surface do not round off as wear takes place, but chip because they are brittle and maintain good serrated cutting edges. Finer mesh granules give a more regular cutting edge so that the mesh of the granules is determined by the working conditions.

Technique. The flame is adjusted to have excess acetylene with the white plume from 2½ to 3 times the length of the inner cone (Fig. 6.40*a*). As the heated surface absorbs carbon, its melting point is reduced and the surface sweats. The rod is melted on to this sweating surface and a sound bond is

Fig. 6.40. (*a*) Hard surfacing flame making the surface sweat.



made between deposit and parent metal with the minimum amount of alloying taking place.

This type of deposit, used for its wear-resisting properties, is usually very tough and is practically unmachinable. The surface is therefore usually ground to shape, but in many applications, such as in reinforcing tramway and rail crossings, it is convenient and suitable to hammer the deposit to shape while hot, and thus the deposit requires a minimum amount of grinding. The hammering, in addition, improves the structure.

In the case of the high-carbon deposits, they can be machined or ground to shape and afterwards heat treated to the requisite degree of hardness.

When using tungsten carbide rods the cone of the flame should be played on the rod and pool to allow gases to escape, preventing porosity. Weaving is necessary to give an even distribution of carbide granules in the matrix. Second runs should be applied with the same technique as the first, with no puddling of the first run since this would give dilution of the hard surface with the parent plate.

Another method frequently used to build up a hard surface is to deposit a surface of cast iron in the normal way, using a silicon cast iron rod and flux. Immediately the required depth of deposit has been built up, the part is quenched in oil or water depending on the hardness required.

This results in a hard deposit of white cast iron which can be ground to shape, and which possesses excellent wear-resisting properties. This method is suitable only for parts of relatively simple shape, that will not distort on quenching, such as camshafts, shackle pins, pump parts, etc.

The use of carbon and copper fences in building up and resurfacing results in the deposit being built much nearer to the required shape, reducing time in welding and finishing and also saving material.

When hard surfacing cast iron, the surface will not sweat. In this case the deposit is first laid as a fusion deposit, with a neutral flame, and a second layer is then 'sweated' on to this first layer. In this way the second layer is obtained practically free from any contamination of the base metal.

It will be seen, therefore, that the actual composition of the deposit will depend entirely upon the conditions under which it is required to operate. A table of alloy steel rods and uses is given at the end of this chapter.

Stellite

Stellite alloys of the cobalt–chrome type with carbon were first developed in 1900 in the US and were the first wear-resistant cobalt-based alloys to be used. Later tungsten and/or molybdenum were added. They are hard and have a great resistance to wear and corrosion and there are now about 20 Stellite alloys available, covering a wide field of resistant surfaces. They can be divided into:

(1) Co–Cr–W–C,
(2) Co–Cr–W/Mo–Ni/Fe–C.

The latter alloys of group (2) have been developed for high-temperature, high-impact wear operations.

The carbon content of the alloys varies from 0.1% to 3.0% and over half of them have a carbon content above 1%. Those with less carbon have a combined carbon plus boron content greater than 1%. (The cobalt-based alloys are discussed in Chapter 1 on hard facing by MMA.)

Stellite alloys available for use with the oxy-acetylene process with the hardness Rockwell on the C scale and VPH are:

> No. 1 53R, 590VPH; No. 4 47R 480VPH; No. 6 42R, 420VPH; No. 12 48R, 500VPH; No. 20 55R, 620VPH; No. 190 52R, 580VPH; No. 2006 44R, 440VPH; No. 2012 49R, 520VPH.

In general, wear resistance increases as the hardness increases, owing to the dispersal of the hard carbides in the somewhat softer matrix. Stellite alloys preserve their hardness at elevated temperatures dependent upon the W and/or the Mo content. Bare tube rods of granulated tungsten carbide or of a 60/40 percentage of tungsten carbide with either Stellite No. 6 steel tube filled with the tungsten carbide or the 60/40 blend.

Tips of Stellite can be brazed on to lathe and cutting tools of all types, giving an excellent cutting edge on a less brittle shank. Stellite, however, can be deposited directly on to surfaces, and in this form it is used for all types of duty, such as surfaces on shafts which have to stand up to great wear and corrosion, lathe centres, drill tips, etc.

Stelliting steel

Preparation. Scale, dirt and impurities are thoroughly removed and the parent metal is pre-heated. Pre-heating and slow cooling are essential to avoid cracking.

Small jets of water, playing on each side of the weld, can be used to limit the flow of heat and reduce distortion, when building up deposits on hardened parts such as camshafts.

Flame and rod. A flame with an excess of acetylene is used, the white plume being about 2½–3 times the length of the inner blue cone. Too little acetylene will cause the Stellite to foam and bubble, giving rise to blowholes, while too much acetylene will cause carbon to be deposited around the molten metal. The tip should be one size larger than that for the same thickness steel plate, but the pressure should be reduced, giving a softer flame. For small parts 5 mm diameter Stellite rods can be used, while thicker rods are used for larger surfaces. Too much heat prevents a sound deposit being obtained, because some of the base metal may melt and mix with the molten stellite, thus modifying its structure.

Technique. The flame is directed on to the part to be surfaced, but the inner cone should not touch the work, both blowpipe and rod making an angle of 45–60° with the plate (Fig. 6.40*b* and *c*). When the steel begins to sweat the Stelliting rod is brought into the flame and a drop of Stellite melted on to the sweating surface of the base metal, and it will spread evenly and make an excellent bond with the base metal. The surfacing is continued in this way.

After treatment. The part should be allowed to cool out very slowly to prevent cracks developing.

Stelliting cast iron

Preparation. Clean the casting thoroughly of oil and grease and pre-heat to a dull red heat.

Technique. Using the same type rod and flame as for Stelliting steel, it is advisable first to lay down a thin layer and then build up a second layer on this. The reason for this is that more of the surface of the cast iron is melted than in the case of steel, and as a result the first layer of Stellite will be diffused with impurities from the cast iron.

The flame is then played on the cast iron and the rod used to push away any scale. A drop of Stellite is then flowed on to the surface, and the flame kept a little ahead of the molten pool so as to heat the cast iron to the right temperature before the Stellite is run on. Cast iron flux may be used to flux the oxide and produce a better bond.

Heat treatment for depositing Stellite

(*a*) Small components of mild steel and steel up to 0.4% carbon. Pre-heat with the torch the area to be faced; hard face the area and cool away from draughts.

(*b*) Large components of mild steel and steel up to 0.4% carbon; small components of high-carbon and low-alloy steels. Pre-heat to 250–350 °C. Hard face whilst keeping at this heat with auxiliary heating flame. Cover and bring to an even heat with flame and cool slowly in dry kieselguhr, mica, slaked lime, ashes or sand.

(*c*) Large components of high-carbon or low-alloy steel; cast iron components; bulky components of mild steel with large areas of Stellite facing. Pre-heat to 400–500°C. Hard face whilst at this temperature. Bring to a dull red even heat and cool slowly as for (*b*).

(*d*) Air-hardening steel (not stainless). When a large area of deposit is required these steels should be avoided. Otherwise pre-heat to 600–650 °C and deposit hard surface whilst at this heat. Then place in a furnace at 650 °C for 30 minutes and cool large components in the furnace and small ones as (*b*).

(*e*) 18/8 austenitic stainless steel non-hardening welding type. Pre-heat to 600–650 °C. Hard surface whilst at this temperature. Bring to an even temperature and cool out as (*b*).

(*f*) 12–14% manganese austentic steel. Use arc process.

Spray fuse process for depositing Stellite

In this process a stellite powder (HV 425–750) or nickel powder (HV 375–750) is sprayed on to the part to be hardened and this layer is then fused on with an oxy-acetylene flame. In this way thin layers up to 2 mm thick can be deposited having little dilution with the parent metal. The alloys are self-fluxing, the deposit has a fine structure, and any inclusions are well distributed. Surfaces having sharp corners and sudden change of section should be avoided and the areas should be rough turned and then shot blasted to obtain a rough surface. The hardfacing powder, cobalt based, nickel based or tungsten carbide, is applied with a gas spray gun using aspirating gas pressure to mix the powder and to disperse it evenly through the flame on to the pre-heated surface to be treated. The particles are in the form of a semi-molten spray when they hit the surface. Jobs should be pre-heated and the gun held about 150 mm from the surface, and after deposition the deposit is porous like other cold-sprayed deposits. The next operation is to fuse the deposit into a sound, wear-resistant coating securely bonded to the parent metal. Because of stresses remaining in the deposit, fusing should be carried out immediately after spraying. It is done with an oxy-acetylene torch with a multi-jet nozzle, the part being first raised to about 350 °C. One area is selected to begin fusing and the temperature raised to 700–800 °C over a small area and part of this is then raised to 1100 °C when glazing of the surface begins, indicating that fusing is taking place. The torch is moved over the area until it is all fused and the whole part finally brought up to an even temperature, cooling being carried out by covering it with heat-insulating substance or heat treatment being given, if required for the parent plate.

With this method of application localized heat is reduced, so that distortion is minimized and thin deposits can be applied with little dilution. Shrinkage amounting to 25% takes place during fusing so this must be allowed for, together with grinding tolerance if required, when calculating the thickness of the sprayed coat.

In the manual torch powder method, the gun and torch are combined in one unit and deposition and fusing are carried out in one operation. The incoming gas is used for mixing and carrying the powder to the flame. The usual method of deposit is by using a carburizing flame with a feather about 2½–3 times the length of the inner cone. A dilution of 1–5% occurs and the thickness of deposit is governed by the rate of flow of powder and movement of the torch (Fig. 6.41*a* and *b*).

Typical applications are: dies, cast iron parts, cement dies, fan blades, feed screws, hammer mill hammers, knives, cams and other metal-to-metal parts, plough shares, pump parts, bearing surfaces of steel shafts, etc. See also hard facing by plasma spray, plasma transferred arc, mechanized TIG, MIG and MMA methods.

Brazing (see also Appendix 9 for rods and fluxes)

Brazing may be defined as 'a process of joining metals in which, during or after heating, molten filler metal is drawn by capillary attraction into the space between closely adjacent surfaces of the parts to be joined'. In general the melting point of the filler metal is above 500 °C but always below the melting temperature of the parent metal.

Since capillarity and hence surface tension are involved in the process it may be convenient to give a brief explanation of some of the principles involved.

The student should refer to BS 1845 which lists the chemical compositions and approximate melting ranges of filler metals grouped under the following headings: aluminium brazing alloys, silver brazing alloys, copper–phosphorus brazing alloys, copper brazing alloys, brazing brasses, nickel-base brazing alloys, palladium bearing brazing alloys, and gold bearing brazing alloys.

Surface tension

If drops of mercury rest on a level plate it will be noticed that the smaller the drop the more nearly spherical it is in shape, and if any drop is deformed it always returns to its original shape. If the only force acting on any drop were that due to its own weight, the mercury would spread out over the plate to bring its centre of gravity (the point at which the whole weight of the drop may be conceived to be concentrated) to the lowest point so that to keep the shape of the drop other forces must be present. As the drop gets smaller the force due to its own weight decreases and these other forces act so as to make the drop more spherical, that is to take up a shape which has the smallest surface area for a given volume. Other examples of these forces, termed surface tension, are the floating of a dry needle on the surface of water, soap bubbles and water dripping from a tap. In the first example the small dry needle must be laid carefully horizontally on the surface. If it is pushed slightly below the surface it will sink because of its greater density. Evidently the surface of the water exhibits a force (surface tension) which will sustain the weight of the needle. If a wire framework $ABCD$, with CD, length x, able to slide along BC and AD, holds a soap film, the film tends to contract, and to prevent this a force F must be applied at right angles to CD (Fig. 6.42). The surface tension is defined as the force per unit length S on a line drawn in the film surface, and since there are two surfaces to the film $F = 2Sx$.

Angle of contact(θ). The angle of contact between a liquid and a solid may be defined as the angle between the tangent to the liquid surface at the point of contact and the solid surface. For mercury on glass the contact angle is about 140°, while for other liquids the angle is acute and may approach zero (Fig. 6.43).

Fig. 6.42

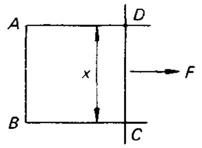

Fig. 6.43

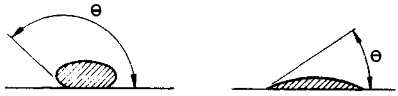


CONTACT ANGLE
(NON-WETTING AND WETTING)

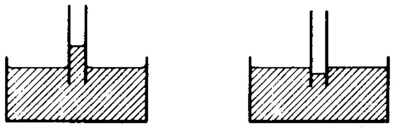
Wetting. If the contact angle approaches zero the liquid spreads and wets the surface and may do so in an upward direction. If the solid and liquid are such that the forces of attraction experienced by the molecules towards the interior of the liquid are less than the forces of attraction towards the solid, the area of contact will increase and the liquid spreads.

Capillarity. If a narrow bore (capillary) tube with open ends is placed vertically in a liquid which will wet the surface of the tube, the liquid rises in the tube and the narrower the bore of the tube the greater the rise. The wall thickness of the tube does not affect the rise and a similar rise takes place if the tube is replaced by two plates mounted vertically and held close together. If the tube or the plates are held out of the vertical the effect is similar and the vertical rise the same. If the liquid does not wet the tube (e.g. mercury) a depression occurs, and the shape of the liquid surface (the meniscus) is shown. The rise is due to the spreading or wetting action already considered – the liquid rises until the vertical upward force due to surface tension acting all round the contact surface with the tube is equal to the vertical downward force due to the weight of the column of liquid (Fig. 6.44).

This wetting action and capillary attraction are involved in the brazing process. The flux, which melts at a lower temperature than the brazing alloys, wets the surface to be brazed, removes the oxide film and gives clean surfaces which promote wetting by a reduction of the contact angle between the molten filler alloy and the parent plate at the joint. The molten filler alloy flows into the narrow space or joint between the surfaces by capillary attraction and the narrower the joint the further will be the capillary flow. Similarly solder flows into the narrow space between tube and union when 'capillary fittings' are used in copper pipe work.

Brazing can be performed on many metals including copper, steel and aluminium, and in all cases cleanliness and freedom from grease is essential. The filler alloy used for aluminium brazing has already been mentioned in the section on oxy-acetylene welding. In the case of the nickel alloys, time and temperature are important. For example copper alloys mix readily with nickel alloy 200 or MONEL® alloy 400 and can pick up sufficient

Fig. 6.44



CAPILLARY ELEVATION CAPILLARY DEPRESSION

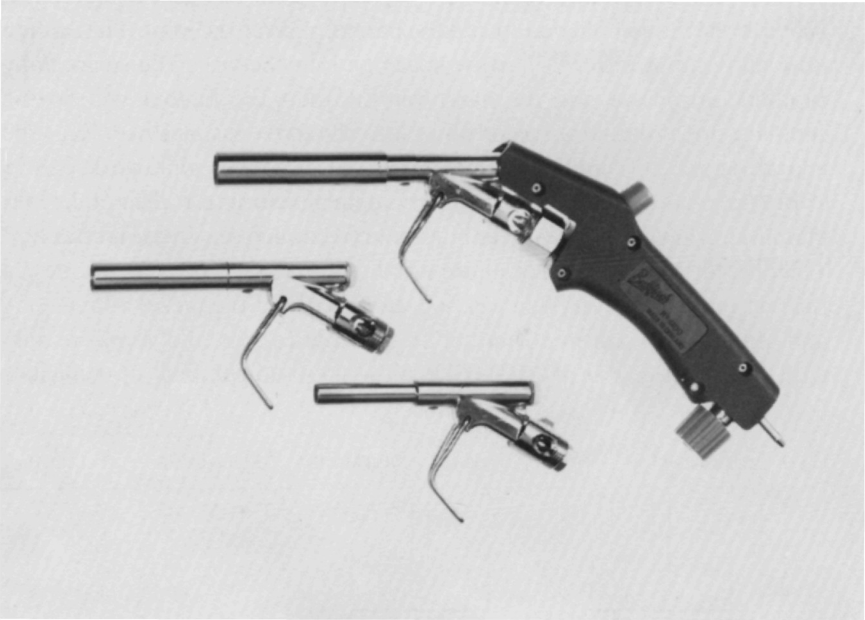
nickel to raise the melting point and hinder the flow of the filler metal. Also chromium and aluminium form refractory oxides which make brazing difficult, so that the use of a flux is necessary. A wide range of brazing alloys are available having a variety of melting points. Fig. 6.45 shows a modern brazing torch using LPG. See appendix for table of general purpose silver brazing alloys and fluxes.

Aluminium brazing

The fusion welding of fillet and lap joints in thin aluminium sections presents considerable difficulty owing to the way in which the edges melt back. In addition the corrosive fluoride flux is very liable to be entrapped between contracting metal surfaces so it is advantageous to modify the design wherever possible so as to include butt joints instead of fillet and lap.

In many cases, however, corner joints are unavoidable and in these cases flame brazing overcomes the difficulty. It can be done more quickly and cheaply than fusion welding, less skill is required and the finished joint is neat and strong.

Fig. 6.45. LP gas brazing torch for brazing, hard and soft soldering. Propane gas recommended, cylinder pressure 7–8 bar. Standard torch pressure 4 bar. Use smaller nozzles for smaller flames. Temperatures up to 950 °C, piezo-electric ignition.



Aluminium brazing is suitable for pure aluminium and for alloys such as LM4, LM18 and for the aluminium–manganese and aluminium–manganese–magnesium alloys, as long as the magnesium content is not greater than 2%.

Preparation. It is always advisable to allow clearance at the joints since the weld metal is less fluid as it diffuses between adjacent surfaces. Clearance joints enable full penetration of both flux and filler rod to be obtained.

Surface oxide should be removed by wire brush or file and grease impurities by cleaning or degreasing. Burrs such as result from sawing or shearing and other irregularities should be removed so that the filler metal will run easily across the surface. Socket joints should have a 45° belling or chamfer at the mouth to allow a lead in for the flux and metal, and to prevent possibility of cracking on cooling, the sections of the surfaces to be jointed should be reduced to approximately the same thickness where possible.

Blowpipe, flame, flux and rod. The blowpipe and rod are held at the normal angle for leftward welding, and a nozzle giving a consumption of about 700 litres of both oxygen and acetylene each per hour is used. The flame is adjusted to the excess acetylene condition with the white acetylene plume approximately $1\frac{1}{2}$ to 2 times the length of the inner blue cone. The rod can be of 10–13% silicon–aluminium alloy melting in the range 565–595 °C (compared with 659 °C for pure aluminium). This is suitable for welding and brazing the high silicon aluminium alloys and for general aluminium brazing. Another type of rod containing 10–13% Si and 2–5% Cu is also used for pure aluminium and aluminium alloys except those with 5% silicon, or with more than 2% magnesium, but is not so suitable due to its copper content if corrosive conditions are to be encountered, but it has the advantage of being heat-treatable after brazing, giving greater mechanical strength.

BS 1845, Filler metals for brazing

	Major alloying elements only (%)				Melting range (°C)	
Type	Silicon	Copper	Iron	Aluminium	Solidus	Liquidus
AL1	10–13	2–5	0.6	Rem.	535	595
AL2	10–13	0–0.1	0.6	Rem.	565	595
AL3	7–8	0–0.1	—	Rem.	565	610
AL4	4.5–6.0	0–0.1	—	Rem.	565	630

In general, ordinary finely divided aluminium welding flux prepared commercially is quite suitable for brazing, but there is also available a brazing flux of similar composition which has a lower melting point.

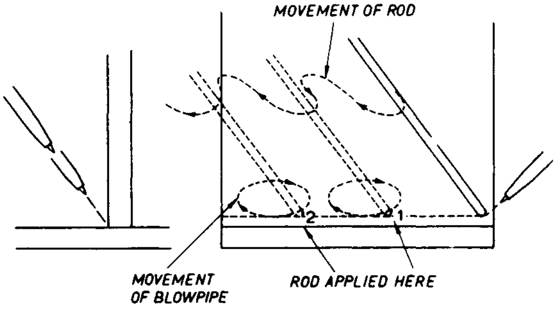
Technique. The flame is held well away from the joint to be brazed and preheating is done with the outer envelope of the flame for about three minutes – this procedure ensures an even temperature, which is essential so that first the flux flows evenly into the joint followed by the filler metal which must displace *all* the flux, otherwise if islands of flux are entrapped corrosion of the joint will occur.

The rod is warmed, dipped in the flux and the tuft which adheres to the rod is touched down on the heated joint. When the correct temperature has been reached the flux will melt and flow over and between the surfaces smoothly and easily. The blowpipe is now lowered to the normal welding position, some rod is melted on to the joint and the blow-pipe moved forward along the seam running the filler rod into the joint. The blowpipe is then raised and brought back a little and lowered again, the above operation being repeated – the blowpipe thus describes an elliptical motion – each operator modifying the technique according to his individual style (Fig. 6.46).

Flux should only be added when the filler rod does not appear to be running freely. Too much flux is detrimental to the finished joint and great care should be taken that the filler rod flows freely into the joint, so as to displace all the flux.

After treatment. The corrosive flux should be removed by the treatment as given for aluminium welding.

Fig. 6.46. Aluminium brazing.



General precautions

The following general precautions should be taken in welding:

(1) Always use goggles of proved design when welding or cutting. The intense light of the flame is harmful to the eyes and in addition small particles of metal are continually flying about and may cause serious damage if they lodge in the eyes. Welding filters or glasses are graded according to BS 679 by numbers followed by the letters GW or GWF. The former are for welding operations without a flux and the latter with flux because there is an additional amount

Table giving some of the chief types of oxy-acetylene welding rods available for welding carbon and alloy steels.

Rod	Description and use
Low-carbon steel	A general purpose rod for mild steel. Easily filed and machined. Deposit can be case-hardened.
High-tensile steel	Gives a machinable deposit of greater tensile strength than the previous rod. Can be used instead of the above wherever greater strength is required.
High-carbon steel	Gives a deposit which is machinable as deposited, but which can be heat treated to give a hard abrasion-resisting surface. When used for welding broken parts, these should be of high carbon steel, and heat treatment given after welding.
High-nickel steel (3½–4%)	Produces a machinable deposit with good wear-resisting properties. Suitable for building up teeth in gear and chain wheels, splines and keyways in shafts, etc.
Wear-resisting steel (12–14% manganese)	Gives a dense tough unmachinable deposit which must be ground or forged into shape, and can be heat treated. Useful for building up worn sliding surfaces, cam profiles, teeth on excavators, tracks, etc.
Stellite	For hard surfacing and wear- and abrasion-resisting surfaces.
Chrome molybdenum steel (creep resisting)	High-tensile alloy steel deposit for pressure vessels and high-pressure steam pipes, etc. Rod should match the analysis of the parent metal.
Chrome-vanadium steel	A high-tensile alloy rod for very highly stressed parts.
Tool steel	Suitable for making cutting tools by tipping the ends of mild or low-carbon steel shanks.
Stainless steel	Decay-proof. Rod should match the analysis of the parent metal.

of glare. The grades range from 3/GW and 3/GWF to 6/GW and 6/GWF, the lightest shade having the lowest grade number. For aluminium welding and light oxy-acetylene cutting, 3/GW or 3/GWF is recommended, and for general welding of steel and heavier welding in copper, nickel and bronze, 5/GW or 5/GWF is recommended. A full list of recommendations is given in the BS.

(2) When welding galvanized articles the operator should be in a well-ventilated position and if welding is to be performed for any length of time a respirator should be used. (In cases of sickness caused by zinc fumes, as in welding galvanized articles or brass, milk should be drunk.)

(3) In heavy duty welding or cutting and in overhead welding, asbestos or leather gauntlet gloves, ankle and feet spats and protective clothing should be worn to prevent burns. When working inside closed vessels such as boilers or tanks, take every precaution to ensure a good supply of fresh air.

(4) In welding or cutting tanks which have contained inflammable liquids or gases, precautions must be taken to prevent danger of explosion. One method for tanks which have contained volatile liquids and gases is to pass steam through the tank for some hours according to its size. Any liquid remaining will be vaporized by the heat of the steam and the vapours removed by displacement.

Tanks should never be merely swilled out with water and then welded; many fatal explosions have occurred as a result of this method of preparation. Carbon dioxide in the compressed form can be used to displace the vapours and thus fill the tank, and is quite satisfactory but is not always available. Tanks which have contained heavier types of oil, such as fuel oil, tar, etc., present a more difficult problem since air and steam will not vaporize them. One method is to fill the tank with water, letting the water overflow for some time. The tank should then be closed and turned until the fracture is on top. The water level should be adjusted (by letting a little water out if necessary) until it is just below the fracture. Welding can then be done without fear as long as the level of the water does not drop much more than a fraction of an inch below the level of the fracture.

The welder should study the Department of Employment memorandum on *Safety measures for the use of oxy-acetylene equipment in factories* (Form 1704). Toxic gases and fine airborne particles can provide a hazard to a welder's health. The Threshold Limit Value (TLV) is a system by which concentrations of these are classified, and is explained in the Department of Employment Technical data notes No. 2, *Threshold limit values.*

7

Cutting processes

Gas cutting of iron and steel

Iron and steel can be cut by the oxy-hydrogen, oxy-propane, oxy-natural gas and oxy-acetylene cutting blowpipes with ease, speed and a cleanness of cut.

Principle of cutting operation

There are two operations in gas cutting. A heating flame is directed on the metal to be cut and raises it to bright red heat or ignition point. Then a stream of high-pressure oxygen is directed on to the hot metal. The iron is immediately oxidized to magnetic oxide of iron (Fe_3O_4) and, since the melting point of this oxide is well below that of the iron, it is melted immediately and blown away by the oxygen stream.

It will be noted that the metal is cut entirely by the exothermic chemical action and the iron or steel itself is not melted. Because of the rapid rate at which the oxide is produced, melted and blown away, the conduction of the metal is not sufficiently high to conduct the heat away too rapidly and prevent the edge of the cut from being kept at ignition point.

The heat to keep the cut going once it has started is provided partly by the heating jet, and partly by the heat of the chemical action.

The cutting torch or blowpipe (Fig. 7.1)

Cutting blowpipes may be either high or low pressure. The high pressure pipe, using cylinder acetylene or propane as the fuel gas,* can have the mixer in the head (Fig. 7.2), or in the shank, while the low pressure pipe with injector mixing can be used with natural gas at low pressure.

---

* Proprietary gases are available and contain mixtures of some of the following: methyl acetylene, propadiene, propylene, butane, butadiene, ethane, methane, diethyl ether, dimethyl ether, etc.

In the high pressure pipe, fuel gas and heating oxygen are mixed in the head (Fig. 7.2), and emerge from annular slots for propane or holes for acetylene (Fig. 7.4).

The cutting oxygen is controlled by a spring loaded lever, pressure on which releases the stream of cutting oxygen which emerges from the central

orifice the diameter of which increases as thickness of plate to be cut increases. An oxygen gauge giving a higher outlet pressure (up to 10 bar) than for welding is required, but the gauge for cylinder acetylene can be the same with pressures up to 1.3 bar. Propane pressure is usually up to 3.5 bar and if natural gas is used no regulator is required but a non-return valve should be fitted in the supply line to prevent flash back.

The size of blowpipe used depends upon whether it is for light duty or

heavy continuous cutting and the volume of oxygen used is much greater than of fuel gas (measured in litres per hour, l/h).

Fig. 7.3 shows a stepped nozzle used for cutting steel sheet up to 4 mm thick and this type is also available with head mixing.

The size of torch varies with the thickness of work it is required to cut and whether it is for light duty, or heavy, continuous cutting.

Adjustment of flame

Oxy-hydrogen and Oxy-propane. The correctly adjusted pre-heating flame is a small non-luminous central cone with a pale blue envelope.

Oxy-natural gas. This is adjusted until the luminous inner cone assumes a clear, definite shape, that may be up to 8–10 mm in length for heavy cuts.

Oxy-acetylene. This flame is adjusted until there is a circular short blue luminous cone, if the nozzle is of the concentric ring type, or until there is a series of short, blue, luminous cones (similar to the neutral welding flame), if it is of the multi-hole type (Fig. 7.5*a* and *b*). The effect of too much oxygen is indicated in Fig. 7.5*c*.

Fig. 7.4

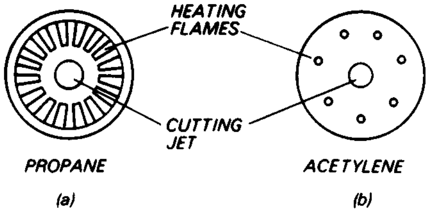

Fig. 7.5

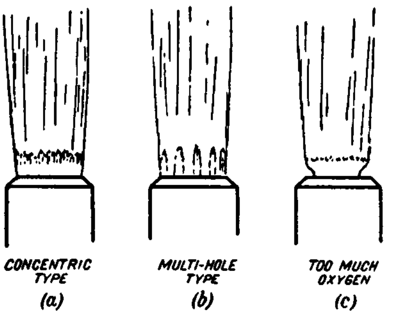


It may be observed that when the cutting valve is released the flame may show a white feather, denoting excess acetylene. This is due to the slightly decreased pressure of the oxygen to the heating jet when the cutting oxygen is released. The flame should be adjusted in this case so that it is neutral when the cutting oxygen is released.

Care should be taken to see that the cutter nozzle is the correct size for the thickness to be cut and that the oxygen pressure is correct (the nozzle sizes and oxygen pressures vary according to the type of blowpipe used).

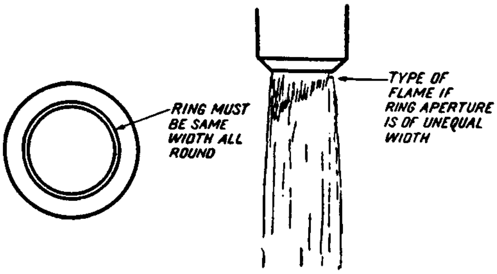
The nozzle should be cleaned regularly, since it becomes clogged with metallic particles during use. In the case of the concentric type of burner, the outer ring should be of even width all round, otherwise it will produce an irregular-shaped inner cone, detrimental to good cutting (Fig. 7.6).

Technique of cutting

The surface of the metal to be cut should be free of grease and oil, and the heating flame held above the edge of the metal to be cut, farthest from the operator, with the nozzle at right angles to the plate. The distance of the nozzle from the plate depends on the thickness of the metal to be cut, varying from 3 to 5 mm for metal up to 50 mm thick, up to 6 mm for metal 50 to 150 mm thick. Since the oxide must be removed quickly to ensure a good, clean cut, it is always preferable to begin on the edge of the metal.

The metal is brought to white heat and then the cutting valve is released, and the cut is then proceeded with at a steady rate. If the cutter is moved along too quickly, the edge loses its heat and the cut is halted. In this case, the cutter should be returned to the edge of the cut, the heating flame applied and the cut restarted in the usual manner. Round bars are best nicked with a chisel, as this makes the starting of the cut much easier. Rivet heads can be cut off flush by the use of a special type nozzle while if galvanized plates are to be cut for any length of time, a respirator is advisable, owing to the poisonous nature of the fumes.

Fig. 7.6



RING MUST BE SAME WIDTH ALL ROUND
TYPE OF FLAME IF RING APERTURE IS OF UNEQUAL WIDTH

To cut a girder, for example, the cut may be commenced at A and taken to B (Fig. 7.7). Then commenced at C and taken to B, that is, the flange is cut first. Then the bottom flange is cut in a similar manner. The cut is then commenced at B and taken to E along the web, this completing the operation. By cutting the flanges first the strength of the girder is altered but little until the web itself is finally cut.

Rollers and point guides can be affixed to the cutter in order to ensure a steady rate of travel and to enable the operator to execute straight lines or circles, etc., with greater ease (Fig. 7.8*a*).

The position of the flame and the shape of the cut are illustrated in Fig. 7.8*b*.

To close down, first shut off the cutting stream, then the propane or acetylene and then the oxygen valve. Close the cylinder valves and release the pressure in the tubes by momentarily opening the cutter valves.

To cut holes in plates a slightly higher oxygen pressure may be used. The spot where the hole is required is heated as usual and the cutting valve

(*a*) (*b*)

released gently, at the same time withdrawing the cutter from the plate. The extra oxygen pressure assists in blowing away the oxide, and withdrawing the nozzle from the plate helps to prevent oxide from being blown on to the nozzle and clogging it. The cutting valve is then closed and the lower surface now exposed is heated again, and this is then blown away, these operations continuing until the hole is blown through. The edges of the hole are easily trimmed up afterwards with the cutter.

When propane or natural gas is used instead of acetylene, the flame temperature is lower; consequently it takes longer to raise the metal to ignition point and to start the cut, and it is not suitable for hand cutting over 100 mm thick nor for cast iron cutting. Because of this lower temperature, the speed of cutting is also slower. The advantages, however, are in its ease of adjustment and control; it is cheap to instal and operate and, most important of all, since the metal is not raised to such a high temperature as with the oxy-acetylene flame, the rate of cooling of the metal is slower and hence the edges of the cut are not so hard. This is especially so in the case of low-carbon and alloy steels. For this reason, oxy-propane or natural gas is often used in works where cutting machines are operated (see later).

The oxy-hydrogen flame can also be used (the hydrogen being supplied in cylinders, as the oxygen). It is similar in operation to oxy-propane and has about the same flame temperature. It is advantageous where cutting has to be done in confined spaces when the ventilation is bad, since the products of combustion are not so harmful as in the case of oxy-acetylene and oxy-propane, but is not so convenient and quick to operate.

The effect of gas cutting on steel

It would be expected that the cut edge would present great hardness, owing to its being raised to a high temperature and then subjected to rapid cooling, due to the rapid rate at which heat is dissipated from the cut edges. Many factors, however, influence the hardness of the edge.

Steels of below 0.3% carbon can be easily cut, but the cut edges will definitely harden, although the hardness rarely extends more than 3 mm inwards and the increase is only 30 to 50 points Brinell.

Steels of 0.3% carbon and above and also alloy steels are best preheated before cutting, as this reduces the liability to crack.

Nickel, molybdenum, manganese and chrome steels (below 5%) can be cut in this way. Steels having a high tungsten, cobalt or chrome content, however, cannot be cut satisfactorily. Manganese steel, which is machined with difficulty owing to the work hardening, can be cut without any bad effects at all.

The oxy-acetylene flame produces greater hardening effect than the oxy-propane flame, as before mentioned, owing to its higher temperature. Excessive cutting speeds also cause increased hardness, since the heat is thereby confined to a narrower zone near the cut and cooling is thus more rapid. Similarly, a thick plate will harden more than a thin one, owing to its more rapid rate of cooling from the increased mass of metal being capable of absorbing the heat more quickly. The hardening effect for low carbon steels, however, can be removed either by preheating or heat treatment after the cut. The hardening effect in mild steel is very small. On thicknesses of plate over 12 mm it is advisable to grind off the top edge of the cut, as this tends to be very hard and becomes liable to crack on bending.

The structure of the edges of the cut and the nearby areas will naturally depend on the rate of cooling. Should the cutting speed be high and the cooling be very rapid in carbon steels, a hard martensitic zone may occur, while with a slower rate of cutting and reduced rate of cooling the structure will be softer. A band of pearlite is usually found, however, very near to the cut edges and because of this, the hardness zone, containing increased carbon, is naturally very narrow. When the cut edge is welded on directly, without preparation, all this concentration of carbon is removed.

Thus, we may say that, for steels of less than 0.3% carbon, if the edges of the cut are smooth and free from slag and loose oxide, the weld can be made directly on to the gas-cut edge without preparation.

Oxygen or thermic lance

This is a method of boring or cutting holes in concrete, brick, granite, etc., by means of the heat generated by chemical reactions.

The lance consists of a tube about 3 m long and 6.5–9.5 mm diameter which is packed with steel wires. One end of the tube is threaded or snap connected and is connected by means of a flexible hose to an oxygen supply. To operate the lance the free end is heated and oxygen passed down the tube. Rapid oxidation of the wires begins at the heated end with great evolution of heat. Magnesium and aluminium are often added to the packing to increase the heat output. The operator can be protected by a shield and protective clothing should be worn. The exothermic reaction melts concrete and other hard materials to a fluid slag and cast iron is satisfactorily bored. Standard gas pipe can be used for thick steel sections.

As an example, a hole of 30 mm diameter and 300 mm deep can be bored in concrete using 1.9 m of lance and 1.0–1.3 m^3 of oxygen at a pressure of 7 bar (100 lb per in^2) in 120 seconds.

Cutting machines

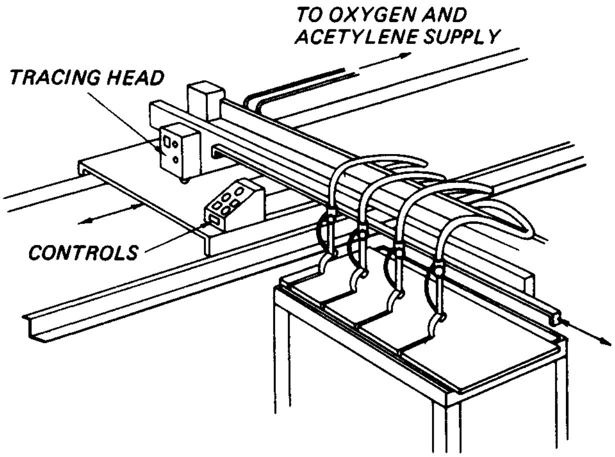
Profiles cut by hand methods are apt to be very irregular and, where accuracy of the cut edge is required, cutting machines are used. The heating flame is similar to that used in the hand cutter and is usually oxy-propane or oxy-acetylene (either dissolved or generated), while the thickness of the cut depends on the nozzle and gas pressures.

The mechanical devices of the machine vary greatly, depending upon the type of cut for which they are required. In many types a tracing head on the upper table moves over the drawing or template of the shape to be cut. Underneath the table or on the opposite side of the machine (depending on the type) the cutting head describes the same motion, being worked through an intermediate mechanism. The steel being cut is placed on supports below the table (Fig. 7.9*a* and *b*).

Simpler machines for easier types of cuts, such as straight line and circles, bevels, etc., are also made.

A typical machine is capable of cutting from 1.5 mm to 350 mm thick, 3 m in a straight line and up to 1.5 m diameter circle. The machine incorporates a magnetic tracing roller, which follows round a steel or iron template the exact shape of the cut required, while the cutting head cuts the replica of this shape below the table.

Fig. 7.9. (*a*) Cutting machine fitted with four cutting heads.



Stack cutting

Thin plates which are required in quantities can be cut by clamping them tightly in the form of a stack and, due to the accuracy of the modern machines, this gives excellent results and the edges are left smooth and even. Best results are obtained with a stack 75–100 mm thick, while G clamps can be used for the simpler types of stack cutting.

Cast iron cutting

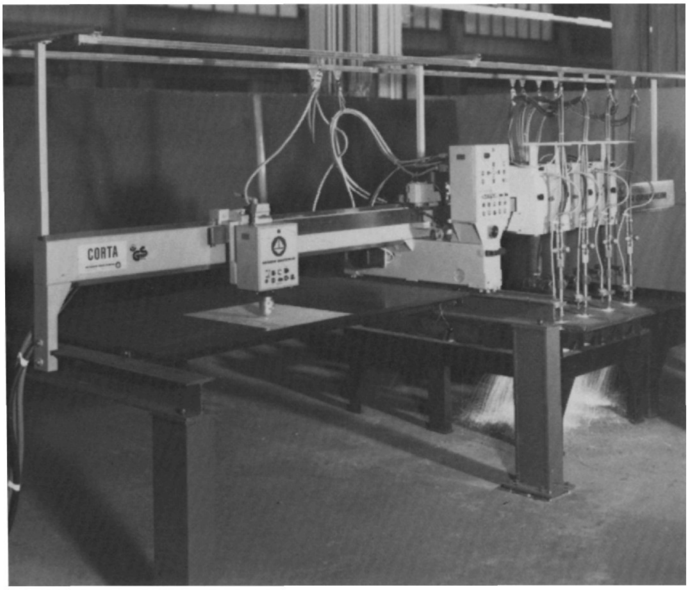
Cast iron cutting is made difficult by the fact that the graphite and silicon present are not easily oxidized. Reasonably clean cuts can now be made, however, using a blowpipe capable of working at high pressure of oxygen and acetylene. Cast iron cannot be cut with hydrogen.

Since great heat is evolved in the cutting process, it is advisable to wear protective clothing, face mask and gloves.

The oxygen pressure varies from 7 N/mm^2 for 35 mm thick cast iron to 11 N/mm^2 for 350 to 400 mm thick, while the acetylene pressure is increased accordingly.

The flame is adjusted to have a large excess of acetylene, the length of the white plume being from 50–100 mm long (e.g. 75 mm long for 35–50 mm thick plate). The speed of cutting is low, being about 2.5 m per hour for 75–125 mm thick metal.

Fig. 7.9. (*b*)



Technique. The nozzle is held at 45° to the plate with inner cone 5–6 mm from the plate, and the edge where the cut is to be started is heated to red heat over an area about 12–18 mm diameter. The oxygen is then released and this area burnt out. The blowpipe is given a zig-zag movement, and the cut must not be too narrow or the slag and metal removed will clog the cut. About 12 to 18 mm is the normal width. After the cut is commenced the blowpipe may be raised to an angle of 70–80°, which will produce a lag in the cut, as shown in Fig. 7.10.

Owing to the fact that high pressures are used in order to supply sufficient heat for oxidation, large volumes of gas are required, and this is often obtained by connecting several bottles together.

Flame gouging by the oxy-acetylene process

Flame gouging is an important extension of the principle of oxy-acetylene cutting by which grooves with very smooth contours can be cut easily in steel plates without the plate being penetrated.

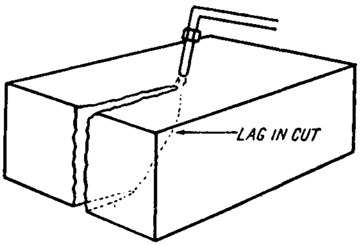
Principle of operation

This is the same as that in the oxy-acetylene process, except that a special type of nozzle is used in the standard cutting blowpipe. A pre-heating flame heats the metal to red heat (ignition temperature), the cutting oxygen is switched on, oxidation occurs and the cut continues as previously explained.

Equipment

The cutting torch may have a straight 75° or 180° angle head together with a range of special gouging nozzles, as shown in Fig. 7.11. The nozzle sizes are designated by numbers and they are bent at an angle which is best for the gouging process. Regulators and other equipment are as for cutting.

Fig. 7.10



Operation

There are two main techniques:

1. progressive,
2. spot.

In the former the groove is cut continuously along the plate – it may be started at the plate edge or anywhere in the plate area. It can be used for removing the underbeads of welds prior to depositing a sealing run, or it may be used for preparing the edges of plates. Spot gouging, however, is used for removing small localized areas such as defective spots in welds.

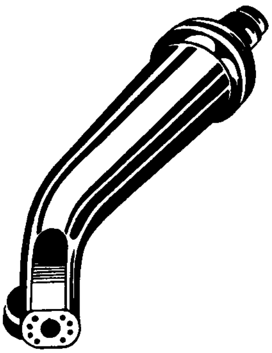
To start the groove at the edge of a plate for continuous or progressive gouging the nozzle is held at an angle of about 20° so that the pre-heating flames are just on the plate and when this area gets red hot the cutting oxygen stream is released and at the same time the nozzle is brought at a shallower angle to the plate as shown, depending upon depth of gouge required. The nozzle is held so that the nozzle end clears the bottom of the cut and the pre-heating flames are about 1.5 mm above the plate.

The same method is adopted for a groove that does not start at the plate edge. The starting point is pre-heated with the nozzle making a fairly steep angle with the plate at 20–40°. When the pre-heated spot is red hot the cutting oxygen stream is released and the angle of the nozzle reduced to 5–10° depending upon the depth of gouge required (Fig. 7.12).

To gouge a single spot, it is pre-heated as usual where required, but when red hot and the cutting stream of oxygen is turned on, the angle of the nozzle is *increased* (instead of, as previously, decreased) so as to make the gouge deep.

The depth of groove cut depends upon nozzle size, speed of progress and angle between nozzle and plate (i.e. angle at which the cutting stream of oxygen hits the plate). The sharper this angle, the deeper the groove. If the

Fig. 7.11. Flame gouging nozzle.



cutting oxygen pressure is too low ripples are left on the base of the groove. If the pressure is too high the cut at the surface proceeds too far in advance of the molten pool, and eventually the cut is lost and must be restarted.

Use of flame gouging

Certain specifications, such as those for fabrication of butt welded tanks, etc., stipulate that the underbead (or back bead) should be removed and a sealing run laid in place. This can easily and efficiently be done by flame gouging, as also can the removal of weld defects, tack welds, lugs, cleats, and also the removal of local areas of cracking in armour plate, and flashing left after upset welding (Fig. 7.13).

Oxy-arc cutting process

In this process the electric arc takes the place of the heating flame of the oxy-acetylene cutter. The covered electrodes of mild steel are in 4 sizes and are of tubular construction, the one selected depending upon whether it is required for cutting, piercing, gouging, etc. They are about 5 to 6 mm outside diameter with a fine hole about 1.5 mm diameter or more through which the cutting oxygen stream passes, down the centre. The gun type holder secures the electrode by means of a split collet and has a trigger controlling the oxygen supply. A d.c. or a.c. supply of 100–300 A is suitable.

The arc is struck with the oxygen off, the oxygen valve is released immediately and cutting begins, the electrode being held at an angle of 60° to the line of cut, except at the finish when it is raised to 90°, and is

consumed in the process. The oxygen pressure varies with the thickness of steel and with the size of electrode being used, about 4 bar (60 lb per in^2) for mild and low alloy steel plate of 8 to 10 mm thick and about 4.5–5.5 bar (70–80 lb per in.^{2}) for 23 to 25 mm thick. In addition to mild and low-alloy steel, and stainless steel copper, bronze, brass, monel and cupro-nickels can be roughly cut by this process.

Arc-air cutting and gouging process

In this process a carbon arc is used with a d.c. supply from a welding generator, or rectifier, together with a compressed air supply at 5–8 N/mm^2.

The equipment comprises a holder for the carbon electrode to which is supplied the first current with *electrode* +ve, and the compressed air which is controlled by a lever-operated valve on the electrode holder.

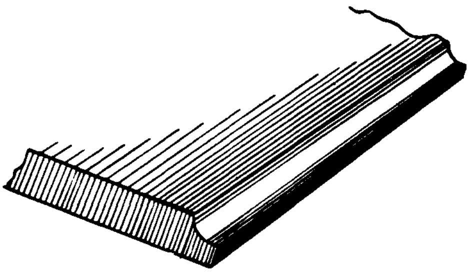
The jaws of the electrode holder are rotatable enabling the carbon electrode to be held in any position and twin jets of compressed air emerge from the head on each side of the carbon and parallel to it, the two jet streams converging at the point where the arc is burning. Air is also circulated internally in the holder to keep it cool.

Operation

The carbon electrode is placed in the holder with 75–150 mm projecting, with the twin jet holes pointing towards the arc end of the carbon.

The carbon is held at approximately 45° to the job to be cut while for shallow gouging the angle may be reduced to 20°. This angle together with the speed of travel affects the depth of cut. The carbons have been specially designed for the process and are a mixture of carbon and graphite covered over all with a thin sheath of copper. The copper coating prevents tapering

Fig. 7.13. Flame-gouged edge of plate, prepared for welding.



and ensures a cut of regular width in addition to enabling higher current to be used and consequently greater speeds of cutting to be obtained.

The carbons range in diameter from 4 mm (75–150 A) to 16 mm (550–700 A) and the higher the current density the more efficient the operation. Too high a current for a given size of electrode destroys the copper coating and burns the carbon at an excessive rate. Normally the copper coating burns away about 20 mm from the arc.

The process is applicable to work in all positions and is used for removing defects in castings, in addition to cutting and gouging. A reasonably clean surface of cut is produced with no adverse effect so that welding can be carried out on the cut surface without further grinding.

Cutting (and gouging) with the carbon arc. The carbon arc, owing to its high temperature, can be used for cutting steel. A high current is required, and the cut must be started in such a spot that the molten metal can flow away easily. The cut should also be wide enough so that the electrode (of carbon or graphite) can be used well down in it, especially when the metal is thick, so as to melt the lower layers. Cast iron is much more difficult to cut, since the changing of the iron into iron oxide is not easily performed owing to the presence of the graphite. Carbon arc cutting does not produce a neat cut, and because of this is only used in special circumstances. Gouging is performed with a very high current and the carbon is held at an angle of 45° to the work. This process is little used as it is very noisy.

Plasma cutting

(see also pp. 190–3, Ions and plasma, and Appendix 14 on lasers)

This process gives clean cuts at fast cutting speeds in aluminium, mild steel and stainless steel. All electrically conducting materials can be cut using this process, including the rare earth metals and tungsten and titanium and it has superseded powder cutting.

The arc is struck between the electrode and the conducting body of the torch. A gas mixture or air passes under pressure through the restricted nozzle orifice and around the arc, emerging as a high-temperature (up to 25000 °C) ionized plasma stream, and the arc is transferred from the nozzle and passes between the electrode and work (Fig. 7.14).

Great improvements have been made in plasma cutting torches by greatly constricting the nozzle and thus narrowing the plasma stream, giving a narrower and cleaner cut with less consumption of power. In certain cases 'double arcing' may occur, in which the main arc jumps from tungsten electrode to nozzle and then to work, damaging both nozzle and electrode.

Power unit

A 24 kVA fan cooled unit has input voltages of 220, 380–415, and 500 and cutting currents ranging from 50 A minimum to 240 A maximum at 100% duty cycle and OCV of 200 V d.c. with heavy duty rectifiers for main and pilot arc control. An automatic pilot arc switch cuts off when the cutting arc is transferred. This size of unit enables metal of up to 40 mm thickness to be cut and edges prepared quickly and cleanly in stainless steel, alloy steels, aluminium and copper (Fig. 7.15).

A 75 kVA unit of similar input voltage has cutting currents of 50–250 A with OCV of 300 V and cutting voltage of 170 V enabling thicknesses of 2.7 to 50 mm upwards, in the previously mentioned materials, to be cut and edges prepared at high speed. The cutting head of either unit can be fitted to a carriage to obtain high speeds of cut with greater precision than with manual cutting.

The gases used are argon, hydrogen, nitrogen, and it should be noted that since high voltages of up to 300 V on open circuit and about 170 V during the cutting process, are encountered, great care should be taken to follow all safety precautions and avoid contact with live parts of the torch when the unit is switched on. All work to be done on the torch head should be with the power supply switched off.

Argon–hydrogen and argon–nitrogen are used for cutting. Any combination of the gases can be selected at will to suit the material and thickness and the actual ratio of the gases will depend upon the operator. The tungsten electrode may be of 1.6 or 2.0 mm diameter and gives a cut of width about 2.5–3.5 mm with a torch-to-work distance of about 10 mm when cutting with about 250 A (the work is +ve).

Since hydrogen is an explosive gas and nitrogen combines with oxygen of the atmosphere to form the oxides of nitrogen (NO, N_2O, and N_2O_4) in the heat of the arc, cutting should be done in a well-ventilated shop (not enclosed in any way) and protective clothing and the correct eye lens protection always worn, with earmuffs for longer periods.

Operation. The unit is switched 'on', current is selected on the potentiometer knob and checked on the ammeter, gases are adjusted for mixture and the torch switch pressed. The pilot arc gas flows and the pilot arc is ignited. The torch is now brought down to about 10 mm from the work (take care not to touch down) and, making sure that all protective clothing including head mask is in order, the torch switch is released and the main arc is transferred to the work. If this does not occur a safety cut-off circuit ensures that the pilot arc current circuit is de-energized after a few seconds.

The arc commences with slow start current and when the thickness of work is pierced, the torch is moved along the plate and if cutting current and speed of travel are correct a steady stream of molten metal flows from the underside of the cut giving a smoothly cut surface. Average currents are in the region of 250 A.

The arc is extinguished automatically at the end of the cut or the torch can be pulled away from the work.

Torch (Fig. 7.14). These can be either hand or machine operated and are supplied with spare electrodes, cutting tips and heat shields. If water-cooled torches of either air or mixed gas are used electrolytic action occurs in the waterways of the torch, due to dissolved minerals in the water. Corrosion occurs and the torch is severely damaged. To prevent this, de-ionized water (about 2 litres per minute) can be used (see p. 346).

Air plasma cutting

In this process, instead of using argon, nitrogen and hydrogen as with the tungsten arc, air is used in its compressed form for both plasma gas and cooling. The high plasma temperature provides rapid cutting with little distortion. Sections up to 30–40 mm thick can be cut in steel, low alloy steel, carbon steel, stainless steel, aluminium and bronze. The process is particularly useful for cutting thinner sections. Air contains oxygen, so rapid oxidation takes place within the torch unless steps are taken to reduce it. The tungsten electrode is therefore dispensed with and, instead, electrode and tip are made as small as possible so that they can be discarded when eroded, and are the consumables in this process. The tip has a body of copper into which a small pellet of hafnium wire, with a fine hole down the middle, is pressed centrally in the nose (Fig. 7.16*d*). Hafnium has a lower melting point (2200 °C) than that of tungsten (3400 °C) but it forms a conductive coating with the oxygen which increases its life due to its higher breakdown temperature. An air tube of various sizes controls the amount of air to the tip. The tip fits into the electrode but does touch it (the electrode is the cathode). In addition, as with plasma welding, the work piece, connected to the return cable to the power unit, is also the anode (Fig. 7.16*c*).

Air is supplied from compressor or cylinders to the torch at a pressure of 5–10 bar and with a volume of about 150 litres per minute. The air must be very finely filtered, dry and free from any oily residues. Of the air fed to the torch head, some passes through the tip and the remainder cools the rear of the tip and, with the rest of the air, circulates through the torch head, cooling it and leaving through a small space between heat shield and diffuser (shroud) (Fig. 7.16). The air which passes through the electrode tip emerges at high velocity to form the plasma stream when ionized.

The power unit is similar to that for gas tungsten cutting (Fig. 7.15). It supplies two electrical circuits. One is supplied at 300 V d.c. open circuit, falling to 100–150 V drop across the plasma when using a current of 20–150 A.

The other circuit is of high frequency (HF) about 4 kV, with a d.c. component of 300 pulses per second. When the switch on the torch handle is pressed, the air gap between tip (nozzle) and electrode breaks down, establishing an arc between them (the pilot arc for ionizing the gap), the air flows through and becomes the plasma stream, for transfer to the cut in the work.

Operation. To operate the unit, the air flow tube, air electrode (jet) and

tip and the amperage required for the thickness to be cut must be chosen. See that the flow of air is unhindered. The torch head is now brought down and held over the plate to be cut. The switch on the gun handle is pressed, the pilot arc established and the gap ionized. The torch head is now brought down to the correct height, as determined by the stand off guide or guard at the plate edge. The plasma is transferred to the work (it is of positive polarity) and the cut commences. The torch head is moved along so that the cut is smooth and continuous and there is a slight trailing angle as it passes through the metal. At the end of the cut the trigger is released and the plasma extinguished, but the air continues to flow for about a minute in order to cool the torch head. This is controlled by a control circuit in the power unit.

The life of the electrode decreases with increasing current. At 150 A for 40 mm thick plate the life is about 30 min, while at 50 A for 15 mm thick plate the life is about 110 min. In any case the electrode should be changed when the insert has eroded to a depth of about 1.5 mm (Fig. 7.16*c*). The nozzle or tip has a longer life but should be changed if the orifice is damaged or enlarged. A loss of cutting power may be the result of melting down due to over-use and is accompanied by a green flame.

A ceramic or high-temperature plastic assembly covers the tip (nozzle) to protect it from spatter and a heat shield is often included between tip and shroud. Air passing through the narrow gap between nozzle and diffuser cools the torch head and guides the cooling air into the cut. Attachments, supplied as extras, can be fitted to the torch to give a longer arc for plasma gouging, this method being quieter than the carbon arc method.

Multiple starts cause rapid erosion of the hafnium pellet, and the use of higher currents has the same effect. The higher the current the shorter the life of the tip (nozzle). Remember that tip and electrode are consumables and should be examined constantly for wear. Most complaints about this process are due to trying to operate the tip or electrode (or both) after their efficient life is past.

Examine tip and electrode and replace or clean, if eroded.

De-ionized water

Water taken directly from a tap contains dissolved carbon dioxide (CO_2) with possibly hydrogen sulphide (H_2S) and sulphur dioxide (SO_2) together with mineral salts such as calcium bicarbonate and magnesium sulphate which have dissolved into the water in its passage through various strata in the earth. These minerals separate into ions in the water, for example, magnesium sulphate $MgSO_4$ separates into Mg^{2+} ions (positively charged) and sulphate ions SO_4^{2-} which are negatively charged. Similarly with calcium bicarbonate ($Ca(HCO_3)_2$) which gives metallic ions, Ca^{2+} and bicarbonate ions HCO_3^{2-}.

By boiling or distilling the water the minerals are not carried over in the steam (the distillate) so that the distilled water is largely free of mineral salts but may contain some dissolved CO_2. Distillation is however rather slow and costly in fuel and a more efficient method of obtaining de-ionized water is now available and uses ion exchange resins. The resins are organic compounds which are insoluble in water. Some resins behave like acids and others behave like alkalis and the two kinds can be mixed without any chemical change taking place.

When water containing dissolved salts is passed through a column containing the resins the metal ions change places with the hydrogen ions of the acidic resin so that the water contains hydrogen ions instead of metallic ions. Similarly the bicarbonate ions are replaced by hydroxyl (OH^-) ions from the alkaline resin. During this exchange insoluble metallic salts of the acid resin are formed and the insoluble alkali resin is slowly converted into insoluble salts of the acids corresponding to the acid radials previously in solution.

The water emerging from the column is thus completely de-ionized and now has a greater resistivity (resistance) than ordinary tap water so that it conducts a current less easily. A meter can be incorporated in the supply of de-ionized water to measure its resistivity (or conductivity) and this will indicate the degree of ionization of the water in the cooling circuit. When the ionization rises above a certain value the resins must be regenerated. This is done by passing hydrochloric acid over the acidic resin, so that the free hydrogen ions in the solution replace the metallic ions (Ca^{2+} and Mg^{2+}). This is followed by passing a strong solution of sodium hydroxide (NaOH) through the column, when the hydroxyl ions displace the sulphate and bicarbonate ions from the alkaline resin.

This process produces de-ionized water, purer than distilled water, easily and quickly.

Water injection plasma cutting

In this process, water is injected through four small-diameter jets tangentially into an annular swirl chamber, concentric with the nozzle, to produce a vortex which rotates in the same direction as the cutting gas (Fig. 7.17). The water velocity is such as to produce a uniform and stable film around the high-temperature plasma stream, constricting it and reducing the possibility of double arcing. Most of the water emerges from the nozzle in a conical jet which helps to cool the work surface.

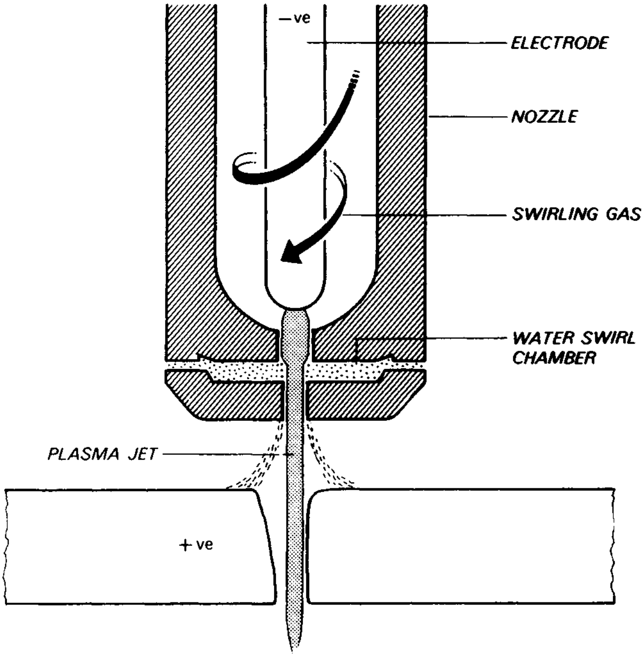
The cut produced is square within about 2° on the right-hand side (viewed in the direction of cutting), whilst the other side is slightly bevelled, caused in general by the clockwise rotation of the cutting gas, which is commercial purity nitrogen. The use of nitrogen reduces cutting costs as it is cheaper than gas mixtures.

The process gives accuracy of cut at high cutting speeds with very smooth cut surfaces. There is little or no adherent dross and the life of the cutting nozzles is greatly increased; mild and carbon steels, alloy and stainless steels, titanium and aluminium are among the metals which can be efficiently cut, in thicknesses from 3 to 75 mm for stainless steel.

The noise and fumes associated with plasma cutting can be reduced by the use of a water muffler fitted to the torch to reduce the noise and by the use of a water table which replaces the normal cutting table and which removes up to 99.5% of the particles and fumes by scrubbing, using the kinetic energy of the hot gases and molten metal stream from the kerf.

This cutting equipment is currently fitted to existing cutting installations up to the largest sizes used in shipyards and including those with numerical control.

Fig. 7.17. The principle of water-injection plasma cutting.



Powder injection cutting

The process of powder injection cutting causes a great deal of fumes to be given off and is one of the less liked operations. As a result it has, in many cases, been superseded by the plasma arc method of cutting of stainless steels, 9% nickel steel and non-ferrous metals. Powder cutting enables stainless steel to be cut, bevelled and profiled with much the same ease and facility as with the oxygen cutting of low-carbon steels.

In cutting low-carbon steels a pre-heating flame raises the temperature of a small area to ignition point. This is the temperature at which oxidation of the iron occurs, and iron oxide is formed when a jet of oxygen is blown on to the area. The heat of chemical combination, together with that of the pre-heating flame enables the oxidation, and hence the cut to continue, the oxide being removed by being blown away by the oxygen jet, resulting in a narrow cut.

For this sequence to occur, the melting point of the oxide formed must be lower than that of the metal being cut. This is the case in low-carbon steel. In the case of stainless steels and non-ferrous metals the oxides formed have a melting point higher than that of the parent metal.

When attempting to cut stainless steel with the ordinary oxy-acetylene equipment the chromium combines with oxygen at high temperature and forms a thin coating of oxide which has a melting point higher than that of the parent steel, and since it is difficult to remove, further oxidation does not occur and the cut cannot continue.

In the powder-cutting process a finely divided iron powder is sprayed by compressed air or nitrogen into the cutting oxygen stream on the line of the cut. The combustion of this iron powder so greatly increases the ambient temperature that the refractory oxides are melted, fluxed, and to a certain extent eroded by the action of the particles of the powder, so that a clean surface is exposed on to which the cutting oxygen impinges and thus the cut continues. The quality of the cut is very little inferior to that of a cut in a low-carbon steel.

Equipment

For hand or machine cutting the powder is delivered to the reaction zone of the cut by means of an attachment fitted to the cutting blowpipe (Fig. 7.18). The attachment consists of powder valve, powder nozzle and tubing. The nozzle is fitted over the standard cutting nozzle and the powder valve is clamped near the gas valves. The iron powder is carried down the outside of the cutting nozzle and after passing through inclined ports, is injected through the heating flame into the cutting stream of oxygen which it meets at approximately 25 mm below the end of the cutting nozzle.

The nozzle is normally one size larger than for cutting the same thickness of low-carbon steel and is held as for normal cutting except that a clearance of 25 to 35 mm is given between nozzle and plate to be cut to allow the powder to burn in the oxygen stream. The great heat produced makes preheating unnecessary on stainless steel and what may be termed a 'flying start' can be made.

The powder dispenser unit (Fig. 7.19) is of the injector type and is a pressure vessel which incorporates:

(1) A hopper for filling.
(2) An air filter.
(3) An air pressure regulator.
(4) A dryer.
(5) An injector unit.

The removable cover enables the hopper to be filled and is fitted with a pressure relief valve which lifts at 0.15 N/mm². A screen for removing overlarge particles from the powder and a tray for the drying agent are fitted.

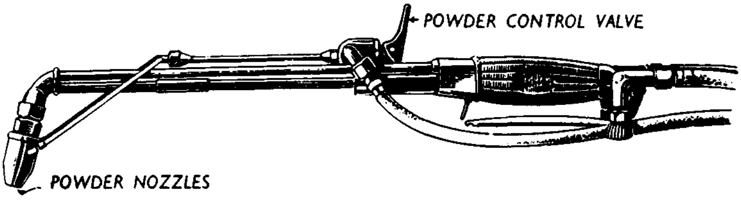
Compressed air flows into the dispenser, picks up powder and carries it along a rubber hose to the cutting nozzle. Nitrogen may be used instead of air but never use oxygen, as it is dangerous to do so. The powder flow from the dispenser is regulated by adjusting the nozzle or by varying the air pressure.

The dispenser should be fed from an air supply of 1.5 m³ per hour at a pressure of 0.3 N/mm². The usual pressure for operating is from 0.02 to 0.03 N/mm².

Since the whole process depends upon a uniform and smooth flow of powder every care must be taken to ensure this. Any moisture in either the powder or in the compressed air can cause erratic operation and affect the quality of the cut.

Silica gel (a drying agent) is incorporated in the dispenser to dry the powder but the amount is not sufficient to dry out the compressed air and a

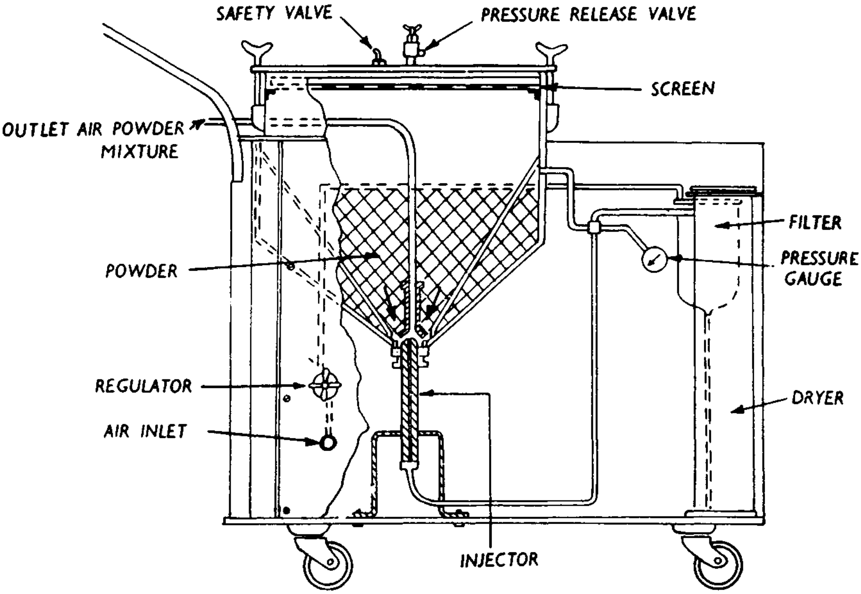
Fig. 7.18. Cutter equipped for powder cutting.



separate drying and filtering unit should be installed in the air line to ensure dry, clean air. The oxygen and acetylene is supplied through not less than 9 mm bore hose with 6 mm bore for the powder supply.

The single-tube attachment discharges a single stream of powder into the cutting oxygen and is used for straight line machine cutting of stainless steel. The multi-jet type (Fig. 7.18) has a nozzle adaptor which fits over a standard cutting nozzle and has a ring of ports encircling it. The powder is fed through these ports and passes through the heating flame into the cutting oxygen. This type is recommended for hand cutting and for profile, straight and bevel machine cutting. Special cutting nozzles are available for this process. These give a high velocity parallel cutting oxygen stream from their bore being convergent–divergent. The pre-heater holes are smaller in number but more numerous and are set closer to the cutting oxygen orifice than in the standard nozzle. This gives a soft narrow pre-heating flame, giving a narrower cut and better finish with a faster cutting speed. Since the iron powder is very abrasive, wear occurs in ports and passages through which the powder passes. By using stainless tube where possible, avoiding sharp internal bends and reinforcing certain parts, wear is reduced to a minimum.

Fig. 7.19. Powder dispenser unit.



Technique

In cutting any metal by this process, correct dispenser setting, dry air and powder, clean powder passages and leak-tight joints all help towards ensuring a good quality cut. The rate of powder flow is first adjusted to the correct amount for the particular work in hand by trial cuts.

Stainless steel. Size of nozzle is one size larger than for the same thickness low-carbon steel. For thicknesses up to 75 or 100 mm the nozzle is held about 25 mm from the plate, for thicknesses up to 150 mm the distance is increased to about 35 mm, while for heavier sections it can be about 50 mm distant. No pre-heating is necessary – an immediate or flying start can be made. Scrap plate may be loosely put together and a single cut can be made, the great heat enabling this to be done in spite of gap between the plates.

Cast iron and high-alloy steels. Technique for cast iron is similar to that for stainless steel but cutting speed is up to 50% slower. With high-alloy steels for example, a 25/20 nickel–chrome steel takes 30–40% longer than for the 18/8 nickel–chrome steel. Pre-heating of high-alloy tool steels is advisable to prevent risk of cracking due to localized heat.

Round carbon steel bars are easily cut by laying them side by side. The cut is done from bar to bar, powder being switched on to start the cut on each bar giving no interruption in cut from bar to bar.

Nickel and nickel alloys. Pure nickel is extremely difficult to cut because it does not readily oxidize and it can only be cut at slow speed in thicknesses up to 25 mm section, whereas INCONEL® and NIMONIC® alloys can be cut up to 125 mm thick, speeds being up to 60% slower than for the same thickness of stainless steel.

Copper and copper alloys. In this operation copper is melted (and not cut) the particles of iron powder removing the molten metal and eroding the cut.

Much pre-heating is required due to the high conductivity of copper and copper alloys – for example – a powder cutting blowpipe capable of cutting 180 mm thick stainless steel can only deal with copper up to 25 mm thick and brass and bronze up to 100 mm thick. A lower cutting oxygen pressure than normal is used and the nozzle moved in a forwards, upwards, backwards, downwards motion in the line of the cut, thus helping to remove the molten metal and avoiding cold spots.

Aluminium and aluminium alloys. The quality of the cut is poor and of ragged profile. Alloys containing magnesium such as MG7 develop a hard surface to the cut due to formation of oxide and this may extend to a depth of 16 mm. As a result powder cutting is limited to scrap recovery. Cutting (or melting) speeds on thinner sections are much the same as for stainless steel, but with thicker sections molten metal chokes the cut, so that large nozzles with reduced cutting oxygen pressures should be used.

Powder cutting can be incorporated on cutting machines and gouging can be carried out as with the normal blowpipe with the same ease and speed, the nozzle being again held further away from the work, to allow space for the combustion of the powder.

Underwater cutting

Underwater cutting of steel and non ferrous metals is carried out on the oxy-arc principle using the standard type of electrode which has a small hole down its centre through which the pressurized oxygen flows to make the cut. By using a thermic electrode, this oxygen stream causes intense oxidation of the material of the electrode, giving a greatly increased quantity of heat for the cut. In both cases the products of the cut are removed or blown away by the oxygen stream.

A d.c. generator is used with the torch negative and the special type earth connexion, connected to clean, non-rusted metal in good electrical contact with the cut, is positive polarity: a.c. is not suitable as there is increased danger of electric shock.

The torch head for ordinary or thermic electrodes is similar. It is tough rubber covered and has connections for oxygen and electric current. The electrodes, usually of 4 mm ($\frac{5}{32}''$) and 4.8 mm ($\frac{3}{16}''$) diameter are securely clamped in the head by a collet for the size electrode being used. A twist of the torch grip clamps and releases the collet and is used for stub ejection. These collets can be changed to allow the torch head to be used for welding (Fig. 5.23).

The oxygen cylinder, fed from a manifold, has a high volume regulator which will give free flow and pressures from 8 bar (118 psi) at 12 m depth to 20 bar (285 psi) at 107 m. In general the oxygen supply to the torch should give about 6 bar (90 psi) over the bottom pressure at the electrode tip.

Ingress of water to the torch head is prevented by suitable valves and washers and replaceable flash arrester cartridge and screen are fitted.

The seal for the electrode in the torch head is made with washers and collet and tightened in place with the torch head locknut. When the electrode is fitted to the head it must bottom on to the washer and be held tight to prevent leakage of oxygen. Note that the thermic type of electrode will continue burning once it has been ignited, even when the electrical supply is switched off, due to the oxidizing action of the gas stream.

Use of equipment

An eyeshield with the correct lens fitted is attached to the outside of the diver's helmet. No oil nor grease should be used on the equipment and there should be no combustible nor explosive materials near to the point where cutting (or welding) is to be performed. Hose connexions should be checked for leaks and all electrical connexions tight, especially check the earth connexion and see that it is in good electrical connexion with the position of the cut. As electrolysis can cause rapid deterioration, all equipment should be continually inspected for signs of this. If any part of the work is above water level, connect the earth clamp to this after checking that there is a good return path from the cut to the earth clamp.

A double pole single throw switch of about 400 A capacity is connected in the main generator circuit as a safety switch. This should always be kept in the 'off' position except when the cut is actually taking place. To begin cutting, strike the arc and open the oxygen valve by pressing the lever on the torch.

When working, the diver-welder must always face the earth connexion so that the cutting is done *between* the diver and the earth connexion. When the electrode has burnt to a stub of about 75 mm in length the diver should call to the surface to shut off the current by opening the safety switch. This having been done the collet is loosened by a twist of the wrist, the oxygen lever is pressed and the stub is blown out of the holder. A new electrode is now fitted, making sure that it sits firmly against the sealing washer, and the handle twisted to lock it in place. Stubs should not be burnt close to the holder for fear of damage. When the safety switch is again placed in the 'on' position cutting can again commence.

When cutting, bear down on the torch so as to keep the cutting electrode against the work so that the electrode tip is in the molten pool and proceed with the cut as fast as possible consistent with good cutting. Spray back from the cut indicates that it is not through the work completely. Keep all cables and hoses from underfoot and where anything may fall on them. Pipes and tubes may be cut accurately to size under water by a hydraulically operated milling machine which is driven around a circumferential guide.

Safety precautions

The general safety precautions which should be observed when welding are listed at the end of the section on oxy-acetylene welding but special precautions should be taken when cutting processes using oxygen are used in the welding shop or confined spaces. Oxygen is present in the atmosphere at about 29.9% by volume and below 6–7% life cannot be sustained.

In Appendix 8 on fire precautions we state that for a fire to occur we need (1) oxygen, (2) fuel and (3) heat.

Oxygen rapidly oxidizes combustible materials and in the case of grease or oil the oxidation reaction produces so much heat that the material may be ignited, thus causing fire or explosion. When cutting with the oxy-acetylene or oxy-propane flame the oxygen (cutting) lever should not be kept open longer than necessary because not only is the compressed gas expensive but it also causes oxygen enrichment of the atmosphere in confined spaces. Should the operator be wearing gloves and clothing that are greasy or oily, the oxidation of this grease and oil may cause burning with evolvement of heat so that the operator may sustain burns and a fire or explosion may endanger life.

Never use compressed oxygen for any other purpose (e.g. in place of compressed air) other than cutting (or welding). Make sure that the ventilation of the area is good – cutting in confined spaces always presents a hazard. Oil, grease and other combustible material should never be in the vicinity where cutting is taking place.

Since oxygen has no smell or taste its presence is difficult to detect and no smoking should be allowed in areas where oxygen is being used.

8

The welding of plastics

Plastics

Plastics are replacing steel and other metals used in construction. They are now used in the home, in gas engineering, farming, sports equipment, and in the automobile industry etc. Equipment made of plastic is lighter than that made of steel, and since welding and fabrication is relatively easy and the cost of repair lower, it will be well to consider some of the processes involved.

Plastics are derived mainly from oil, coal and wood. Polystyrene and polyvinylchloride (PVC) are examples of those derived from oil and coal while the cellulose types (such as cellulose acetate and ethylcellulose) are produced from wood. Plastics consist of larger molecules built up into chains arranged randomly, from single molecules (monomers) by a process of polymerization, assisted by a catalyst. (A catalyst is a substance that accelerates a chemical reaction but undergoes no permanent change during the reaction.) If differing monomers are used, copolymers are produced from which the characteristics of the original monomers cannot be obtained.

There are two main types of plastic: (1) thermo-setting and (2) thermoplastic. A thermo-setting plastic is one that softens when first heated and is then moulded into the required form. Upon cooling it sets hard and gains its full strength. Upon reheating it does not again soften and thus cannot be reshaped. An example of a thermo-setting plastic is that made from phenol and formaldehyde, which with an acid catalyst gives a soluble and fusible resin used in varnishes, and with an alkaline catalyst gives an infusible and insoluble resin (Bakelite).

Thermoplastic substances soften each time they are heated and can be reshaped again and again, regaining their rigidity and strength each time upon cooling. Foil, thin and thicker sections, fabrications, repairs to automobile components and welding in general, can be successfully carried out on thermoplastics.

Welding may be by: (1) external heating, i.e. hot air, hot plate, resistance and RF processes; (2) external movement, i.e. friction or spin, ultra-sonic and other vibrations (100–240 Hz); (3) adhesive, i.e. cyanoacrylates (super-glue). Method (1) is of the most interest to the welder, and hot air and hot plate will be considered in detail.

Table 1 gives the thermoplastics most commonly used for fabrication and in repair work, while Table 2 indicates tests which may be carried out to identify a plastic by removing a shaving from it and burning it in a low flame, carefully observing the results. It is essential that rod and parent plastic should be compatible. To ensure this the makers of plastic welding equipment supply small bundles of various rods as given in Table 1. Tests are carried out on the given plastic with each of the rods until one is found that fuses well and easily into the parent plastic. Compatibility of rod and plate cannot be stressed enough. Note, however, that flame or burn tests

Table 1. *Types of plastic suitable for welding*

Identification	Plastic	Welding temperature (°C)
ABS and ABS/PC	Acrylonitrile-butadiene-styrene and ABS/polycarbonate	350
PVC high density	Polyvinylchloride hard	300
PVC low density	Polyvinylchloride soft	400–500
PC	Polycarbonate and polycarbonate modified	350
PE high density (HDPE)	Polyethylene high density	300
PE soft density (SDPE) (polythene)	Polyethylene soft density	270
PP	Polypropylene	300
PA	Polyamide	400
PP/EPDE	Polypropylene 3-ethylene-diene rubber	300
PUR (polymer alloy)	Polyurethene (not all types are weldable)	300–350
PBT	Polybutylene tetraphthalate	350
Acrylics (e.g. PMMA)	Resins. Usually transparent, e.g. polymethyl methacrylate	350

Note. Glass-reinforced plastics are not generally weldable and foam-filled PU should not be welded.

are little used nowadays because of the difficulty in differentiating between plastics with the same burning characteristics.

Welding thin sheets

Thin sheets are welded by applying heat and pressure to the joint. The sheets are overlapped and then passed between two rollers; the width of roller determines the width of the weld. One of the rollers is motor driven and can be heated by an electrical element. The other roller is free rolling and serves only as a back pressure for the heated roller. The variables are therefore: (1) the temperature of the heated roller, (2) the speed at which the surfaces to be welded pass between the rollers, and (3) the pressure between the rollers. The two surfaces to be welded together pass when in the spongy state – just below melting. The heating element for the main roller has a potentiometer control and the element conducts its heat to the roller. To operate, the temperature is selected for the given plastic (e.g. PVC), for which welding temperature is 300–500 °C. The motor is set at the correct speed to rotate the driven roller, and finally the pressure between the rollers is set. If the current is too low (temperature), or the pressure and speed of travel between the rollers too high, the two sheets will not weld together. If the current is too high and the speed of travel too low, the sheets will be welded together only in certain parts and holes will appear. It will be appreciated that the three variables are notoriously difficult to adjust correctly. Modern machines greatly simplify this procedure. Note that the process is similar in many ways to seam welding (p. 208). If the roller is hand-operated (usually for simple welds only) a smooth surface, under the part to be welded, is fixed so that it takes the place of the bottom roller (Fig. 8.1*a*). Again the temperature of the heating element is set and the roller unit moved down the seam with a medium pressure. As before, if the speed is too high the sheets will not

Table 2. *Tests for identification of plastics*

Plastic	Observations
ABS	Sweet smell; burns with a black sooty flame not self-extinguishing
PC	Burns with black sooty smoke; not reliably self-extinguishing
PE	Smelly and feels like a wax; burns like a wax candle and drips
PP	Similar to PE; feels like wax and smells and drips like wax
PA	Smells like burnt horn; flame not self-extinguishing; stringy
ABS/PC	Sweet smell; black sooty smoke; flame not self-extinguishing
PVC	Burns with black smoke and an acrid smell; not self-extinguishing

be welded together, while too slow a speed results in an unsatisfactory weld with holes down the length of it. The weld must be mechanically sound and continuous. Fig. 8.1(*b*) shows a taped seam welded with hot air from a gun.

Hot air (or gas) welding

Guns or torches. The guns for this method of welding operate on the same principle as a hair dryer, in which a stream of air, propelled by a fan driven by an electric motor, flows over a heated electric element. They are available in various voltages and power loadings: 200–240 V, 1500 W, or 110–120 V, 1700 W and lower voltages if required. Hot gas guns were originally supplied with compressed carbon dioxide or nitrogen but most of them use air nowadays, although the term hot air gun includes hot gas guns.

Some guns have an electric motor in the body of the gun, from which

OR DIRECTION OF TRAVEL OF SHEETS
(b)

the air is supplied, while others use air supplied from an external compressor. In the latter, there are two leads to the gun: the electricity supply for the heating element and the compressed air supply. This type of gun is lighter and of smaller diameter than the type with an electric motor in the body. However, the gun with the motor has the advantage that there is only one cable feeding the motor and element (Fig. 8.2). In both types the air is blown over an electric element, the temperature being accurately controlled (by potentiometer). There is a switch on the outside of the body of the gun, clearly marked so that any temperature between 300 °C and 600–700 °C can be selected for the air issuing from the gun. In some guns the heating element is easily replaceable. The volume of air passing over the element is controlled by a movable shutter over the air intake. The gun barrel gets very hot during use and should on no account be touched. Some guns have an outer shield over the barrel to prevent it being touched accidentally.

Nozzles. A variety of nozzles are available, all having either a tight push-on fit, locked on with a clamp ring and screw, or a screwed-on fit. These

nozzles are obtainable with diameters 3 mm, 4 mm and 5 mm I/D. The following are the most important.

The tack welding nozzle has an open mouth for the hot air, and there is a blunt toe on its front or toe end (Fig. 8.3). The sheets to be welded are close butted together, the hot air from the gun softens the edges of the sheets for the preparation to welding condition and the blunt toe draws the edges together as the gun moves along the surfaces, with the angle of the base of the nozzle about 15–30° to the seam of the joint. The tack weld has little strength and should not be subjected to any load. It is for positioning only and to ensure fusion at the bottom of the weld.

The speed welding nozzle (Fig. 8.4) consists of two tubes – either round or triangular – joined at the bottom end. One tube is for hot air and the other for the rod (round, triangular (profiled) or tape as required). The unit is pushed or screwed onto the gun. The hot air tube has a small-diameter tube inside it down which the hot air passes. At the bottom end is a baffle plate with a 3 mm hole in it, and the bottom of the hot air tube finishes about 20 mm from the baffle so that during welding some of the

WIDE BAND PRESSURE ROLLER
SPEED WELDING NOZZLE FOR TAPE

air passes through the baffle hole and preheats the joint, while the rest of the hot air is available for the welding operation, enveloping the base of the rod and the edges of the preparation. The rod to be used is passed down the other tube in which it should be an easy sliding fit.

The rod is preheated by the tube, and a shoe on the front of the nozzle rests on the completed weld. There is also a speed welding nozzle with no baffle plate and a simple mixing chamber at the base. Speed welding is dealt with in detail later. Some units have a swing back tacking unit to save time when changing nozzles. There are special high speed nozzles for left-hand and right-hand welding in tight corners, and tank openings etc. Nozzles are available for 3, 4, 4.5, 5 and 6 mm round, 4 × 4 × 4 mm,

5 × 5 × 5 mm, 6 × 6 × 6 mm triangular rods, and sections for special use such as 5 × 5 × 4 mm, 6 × 4 × 4 mm profiled (see Fig. 8.5).

Preparation

Sheets up to 3 mm thickness require no preparation. They can be butted together and a tape of the same material and about 20–40 mm wide welded along the seam (Fig. 8.1*b*). This is followed immediately by using a hand-pressed roller to complete the operation. Very thin sheets of

PVC or polythene can be welded together by a heated wheel and hand pressure along the seam, or automatically in a machine which heats the roller and supplies pressure and movement.

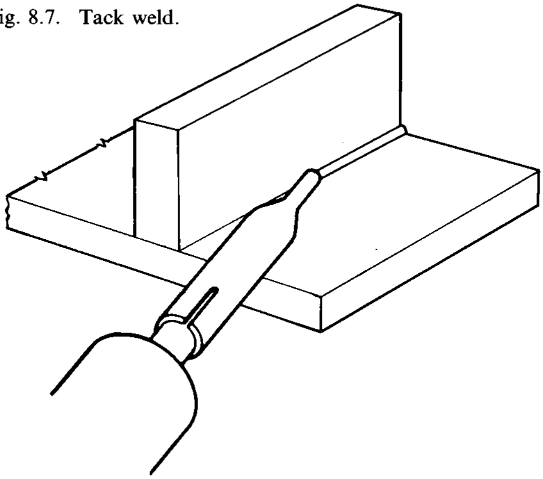
When hand welding, sections up to 6 mm thick can be prepared with a 65–90° V, while sections of greater thickness can have either a single V of 65–85° or a double V of 70–80° (see Fig. 8.6). If the tack welding nozzle is used there is no need to allow any gap between sections.

If cracks are to be welded up in, for example, a car spoiler or bumper, they should be carefully inspected and a small hole, say 2 mm diameter, drilled at each end of the crack to prevent it travelling any further during welding. The plastic to be welded is then identified if possible, and a suitable rod selected. If identification is not possible, one rod at a time is selected from a bundle of rods of varying types, supplied by the manufacturers, until a rod is found that will fuse very well with the parent plate when heat is applied. It is essential to have rod and parent plate 'compatible' so that fusion results in a sound bond. In each case the temperature of the hot air to be used is selected on the gun.

Tack welding

The parts to be welded are placed in position and lined up. The gun, with tack welding nozzle on, is allowed about 2 minutes to heat up, and the front or toe of the nozzle is placed on the bottom of the commencement of the seam to be welded. The nozzle is held in this position until the sides of the weld begin to sweat and the gun is kept at an angle of about 30–40° to the seam and drawn along the seam bringing the two sides together and the tack weld is completed (Fig. 8.7). When cool, the tacking nozzle is exchanged for a straight or cranked standard nozzle.

Fig. 8.7. Tack weld.

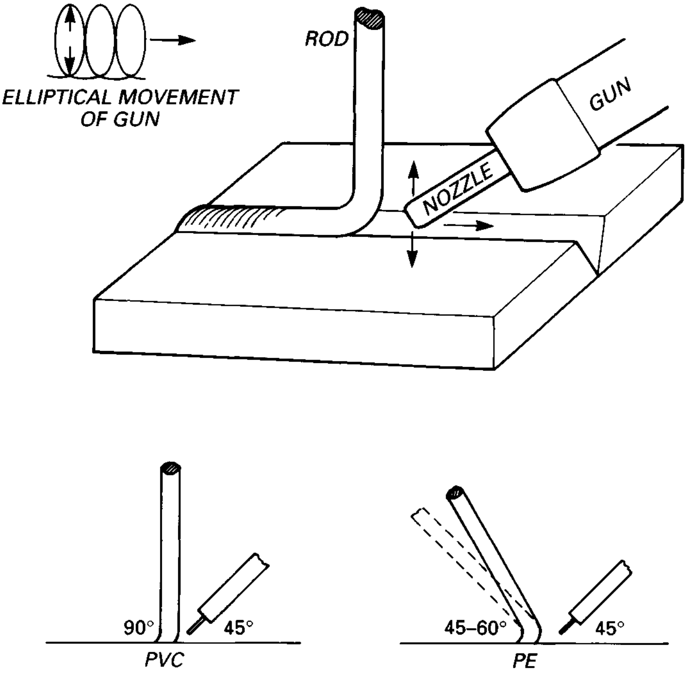


General welding

The rod is held at right angles to the weld at its commencement and hot air from the gun is played on the bottom of the rod and the parent plate until the rod begins to melt, spongily, into the prepared joint. The gun is held at an angle of about 45° to the seam, and moved up and down pendulum fashion with an amplitude of about 20–30 mm and a slight elliptical bias, as shown in Fig. 8.8. As the weld progresses down the seam with the gun preceding the rod, there should be a slight hesitation at the bottom of the stroke to ensure good fusion with the parent plastic. The rod softens and flows easily into the prepared groove with a minimum of hand pressure, say 1.5–2.5 kg. Any sudden reduction of pressure (e.g. when changing position of the fingers on the rod) may cause the rod to lift from the weld and, by trapping air, weaken the weld.

The rod angle is 90° to the weld for PVC, but for polypropylene and polyethylene the rod angle should be 45–60° in order to exert sufficient downward pressure on the rod. A reduced angle for PVC may produce cracks in the finished weld on cooling. To finish a weld, rod movement is stopped and heat applied to where the rod meets the parent plastic. The heat is then removed, keeping a downward pressure on the rod. The rod

Fig. 8.8. Down hand butt weld.



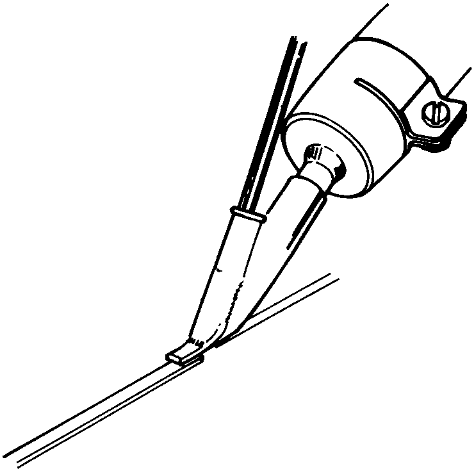
is then allowed to cool and is twisted off. Continuation of a weld can be performed by cutting the weld where it finishes at an angle of about 30° and starting the new weld at this point.

If a weld is to be made right around a pipe, the finish of the weld should overlap the beginning of the weld by about 10–15 mm and not finish alongside it. Using a wide slot nozzle, a tape welded seam can be made to fasten two sheets of plastic butted together. (See section on machine welding.)

Speed welding

The speed welding nozzle, as already described, is fitted to the gun. The welding rod or coil is prepared by sharpening one end to a pencil or chisel point. It is then pushed into the feed tube on the nozzle (and must be an easy sliding fit) until about 2.5–3.5 mm protrudes from the end. The tube on the nozzle is obtainable in various types of section, corresponding to the available rods (see Fig. 8.5). The gun is now held vertically at a point about 65–85 mm above the surface, thus preheating it. The gun, still held vertically, is brought to the commencement of the weld and the sharp end of the rod pushed in so that the sharpened end projects beyond the start of the weld at the front of the nozzle. Hand pressure is kept on the rod at the start, in order to obtain good fusion. When rod and parent plastic are completely softened and the rod begins to fuse into the plastic, the weld commences and the angle of the gun is lowered to about 45° to the line of weld. It is then drawn slowly down the weld preparation, the rod needing little or no feeding and only slight guidance. Remember that

Fig. 8.9. Speed welding.



the angle between the gun and the weld determines the rate of welding, since the preheat hole varies the amount of preheat (Fig. 8.4). When the welding rate is too slow there are charred edges to the weld (PVC), when the rate is too high, there is incomplete fusion with no flow lines. The completed weld should be smooth with a faint wash visible down each side, an indication of good fusion of rod and parent plastic (Fig. 8.9). Note that if cracks are being repaired they should be welded in a continuous run, with, if possible, no stopping. To terminate a weld the gun is brought to the near vertical position and the rod is cut off by slipping the nozzle off the rod, leaving it standing attached to the weld. When cool it can be cut off close to the weld. If multi-layers are required (Fig. 8.5) each run should be allowed to cool before the next is applied. Since thermoplastics are poor conductors of heat, the stresses that arise during welding are concentrated in a smaller area than when welding metals. When welding V-prepared joints, the use of a profile rod and the process of speed welding reduces the stresses and accompanying strains. Note that the expansion coefficient of plastics is many times greater than that of steel.

Practical hints

At first, speed welding appears more difficult than that with an ordinary nozzle, because of the difficulty in obtaining penetration of the weld when starting. The first attempts result in no penetration until the weld has started to be made. It is difficult to heat both rod and plate (keeping some pressure on the rod) until the plate is hot enough to begin the operation. If the welder is too slow, the welding rod in the tube feeding the weld (which is fairly spongy due to preheating in the tube) quickly becomes charred, and the tube becomes blocked by the charred rod. It must then be cleared by pushing a steel rod of just smaller diameter than the tube through it. To overcome this the plates to be welded are preheated with the gun held vertically and then the pointed rod is immediately pushed quickly down the tube and the end guided under the shoe of the nozzle. The gun is held in this position until the rod melts into the parent plate; the angle of the gun is quickly reduced to about 45° and the weld commences immediately and must not stop, the rod being fed automatically by the welding operation and only guided by the fingers. If it is a longer weld, the coil of welding rod can be slipped over the welder's arm onto the shoulder whence it feeds itself automatically into the weld. If difficulty is met in starting the weld, use a small run on plate until the desired time for a good start is found. Keep the underside of the nozzle clean with a wire brush.

Machine (tractor) welding

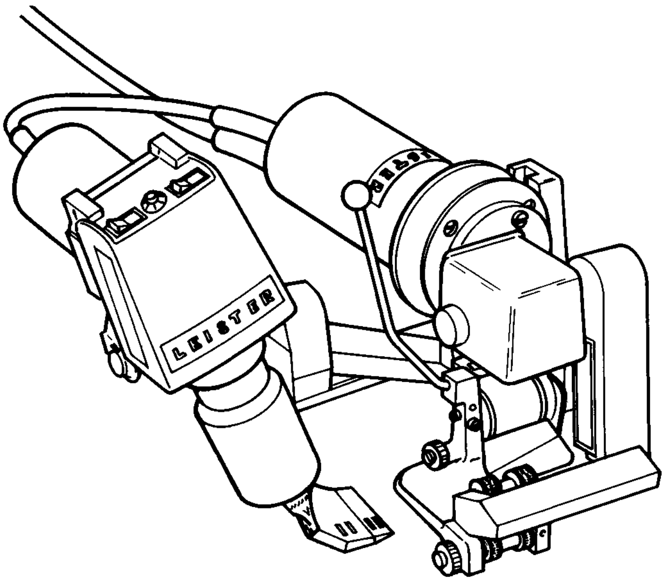
Long seams in plastic sheets (e.g. PVC and polythene) can be welded together by moving a hot air gun suitably mounted and driven by an electrically driven tractor; for ease of replacement the heating element is of the plug-in type (Fig. 8.10).

The sheets may be butted together and a tape of the same material as the sheet and about 20–50 mm wide placed across the length of the joint and the tape welded to the butted seam, followed, where required, by a roller which presses the tape tightly to the seam. The machine is available as 220–240 V, 4.2 kW and 380–400 V, 5.2 kW, with other voltage ranges and loadings for various models. The machines are available for tilt welding (welding on roofs) and the speed is infinitely adjustable between set ranges, e.g. 1–3, 1–6 and 1–12 m/min as required.

The second method much used is overlap welding. The plastic sheets are overlapped up to 100 mm and sand or other material is placed beneath, so as to give a firm underside and one that will not damage the welding process. A test channel may be included, so that the joint can be tested from 2 to 5 bar for any leaks, which can be sealed by hand operation.

With the correct temperature selected and the correct speed of travel

Fig. 8.10. Leister hot air automatic welding machine for overlap welding of thermoplastic film.



the machine produces an excellent weld between the sheets using a wide slot nozzle. For thin plastic sheets (e.g. bags) welding can be performed by a hand or machine driven roller. In both cases speed and temperature must be absolutely correct. Using a hand-held automatic welder, vertical and overhead seams about 10 mm thick can be tape welded and a test channel incorporated.

High frequency spark testing

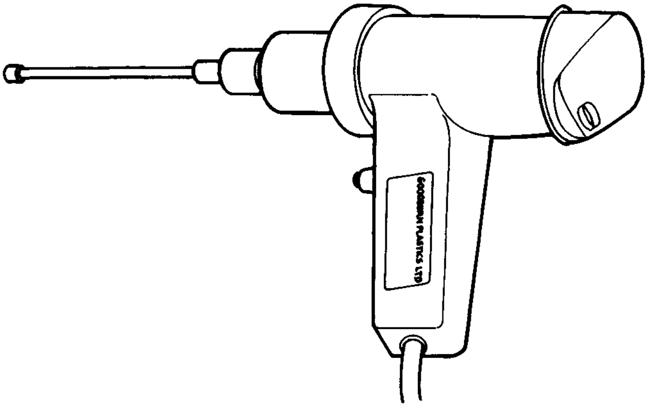
Among the many uses of the high frequency spark tester is the testing of welded joints for porosity and, where required, the testing of the parent plastic for the same defect.

The spark tester is in the form of a light weight gun (Fig. 8.11), and is made for 100–125 V or 220–250 V supply, the loading being only 30 W so that it can be used from any 3-pin socket. The testing voltage is 55 kV maximum and the frequency 200 kHz.

Operation

There is a voltage control on the spark gun, which is important since any sheet or dielectric will break down if the applied voltage is too high. There is a probe fitted to the gun, onto which the high voltage is applied; the probe is then brought near an earthed metal plate and the trigger pressed. The sparks which emanate from the probe are adjusted in length until they are just a little longer than the thickness of the plastic and weld to be tested. The thinner the plastic, the smaller the voltage that

Fig. 8.11. High frequency spark gun (Goodburn).



must be applied, because too high a voltage puts greater strain on the plastic (the dielectric).

The plastic weld under test is placed on the earthed metal plate and the gun switched on. The probe is then moved over the surface of the joint or other surface under test. When any defect is passed over, there is a bright spark and a hissing sound. The position of the defect is marked and the remainder tested as before. The defects are then repaired and the tester again moved over the positions of the faults to ensure that they have been correctly repaired. All plastics including nylon can be tested for plate or weld porosity using the probe from the gun, the material to be tested lying on the earthed metal plate.

Hot plate (or hot iron) welding

The parts of, say, polyethylene or PVC should have uniform profiles and diameters (e.g. pipes). The ends are prepared with a pipe-cutting tool and are lined up with one another using a jig. The ends are then lightly cleaned, kept separated and not touched. The hot plate, which may be of nickel-plated steel or aluminium, for example, is placed between the ends to be welded and the parts moved up to the plate.

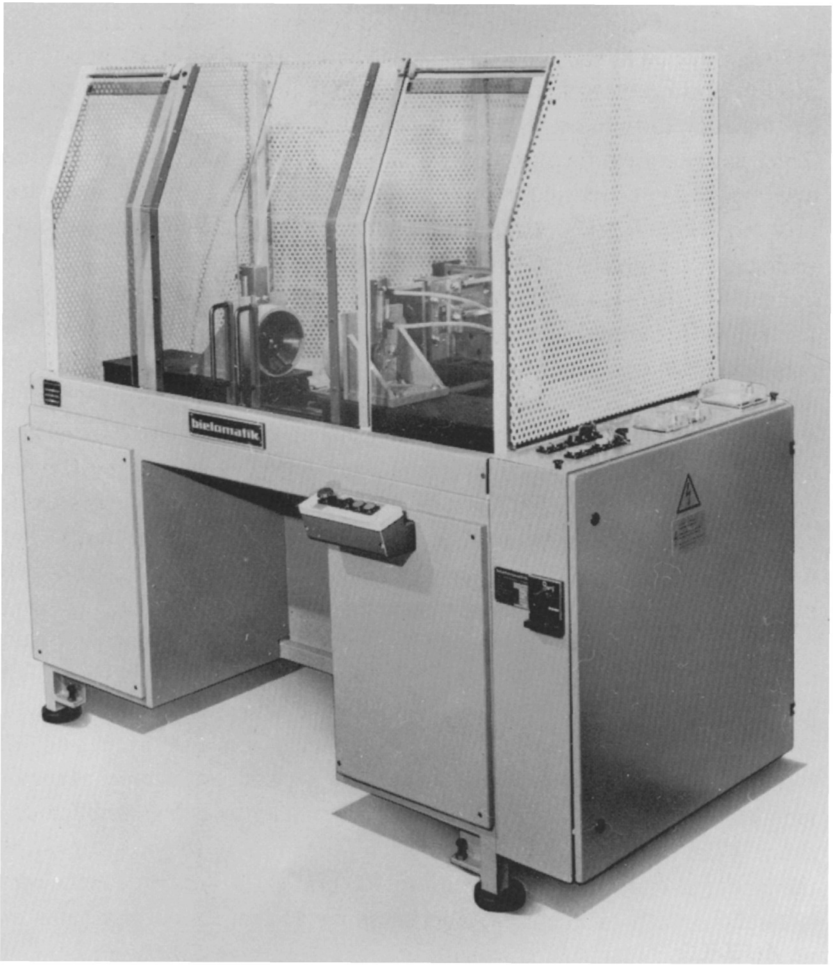
The plate (Fig. 8.3) can be heated electrically or with a hot air gun until the ends of the parts are spongy and soft, the time for which they are in contact with the plate being critical, as this determines the temperature rise of the parts. With electric heating the current is switched off automatically after a given time, both current and time being variable. With the hot air gun care must be taken not to overheat the parts. When the current is switched off the plate is immediately removed and the part ends, now in the spongy condition, are brought together and pressure applied by hand or mechanically until the parts are cool. The flash is then removed and the weld is complete. Fusion has taken place throughout the part ends and an excellent bond is obtained.

Pipes of polyethylene, coloured yellow for gas, blue for water and black for sewage, are much used today and are jointed in this way. The generator used in the field is generally 110 V and equipped with an automatic timing device. Sockets, caps, reducers, tees and simple and self-tapping saddles are available for use with gas and water pipes. Pipes of length 50, 100 or 150 m are available, longer lengths being supplied on a drum. Wall thickness should be selected according to the pressure within the pipe and can vary from 20 mm to 500 mm O/D. Absolute cleanliness is essential with excellent fit, and scraping and other cutting tools are used.

Hot plate welding by machine

Hot plate welding is now used for the production of more complicated assemblies (e.g. in the automobile and domestic industries) which are not suitable for injection, blow moulding or extrusion. Several types of jigs and fixtures are used for variety of mouldings giving watertight sealing, enabling different types of material to be welded together with accurate dimensions and small tolerances.

Fig. 8.12. Horizontal hot plate plastics welding machine. Hand loaded, fully automatic welding cycle (Bielomatik). Optional extras include: vacuum pumps, mechanical clamping. Also available are special adaptations of machine sequences.



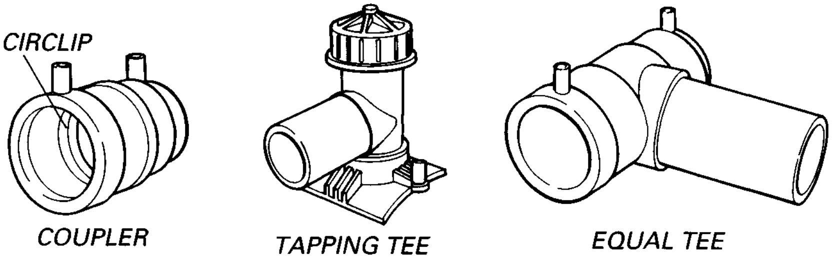
The parts to be welded are loaded onto the upper and lower plattens of the machine (Fig. 8.12). The fusion faces are then plasticized by being brought into contact with the hot plates, which are retracted automatically when the correct plasticizing point is reached. The mouldings are then brought together under pressure as with other types of hot plate welding. Upon cooling the assembly is unloaded from the machine.

Complicated assemblies can be produced more cheaply in this way, because if one part of the assembly is damaged or cracked, that part can be repaired by welding after correct preparation in the manner described in the section on hot air welding.

Electric fusion welding

This method can be performed using fittings such as couplers, reducers, branch saddles etc., which have electrical resistance coils moulded into each fitting. The ends of the heating elements in each fitting are brought to two connecting pillars. Power for the element is supplied from a generator fitted with an automatic timing control, which is essential since it identifies the fitting and gives the welding current and time for each operation. The generator is rated as 40 V and 50 A maximum. Before pipes are joined, they are prepared by machining the ends with a cutter, scraped if necessary, and scrupulously cleaned. They are then pushed into the coupling which has a central circlip to ensure that they are pushed in by an equal amount (Fig. 8.13). The terminals of the fitting are connected to the generator and the correct current and timing for the welding operation is automatically selected. This method is suitable for laying pipes in trenches. When pipes and coupling are brought to the correct temperature they are quite spongy or in a plasticized state; coupling and pipes fuse together at this stage. The electrical wires are disconnected from the pillars and the coupling is allowed to cool. The work may be done in a narrow trench when required and the coupling, or

Fig. 8.13. Types of joints and fittings required for electric fusion welding.



any type of fitting being used, is left in position in the trench, which is then filled in. The various joints made in this way can be subjected to tests for internal pressure (say 10 bar), tensile strength and impact for saddles.

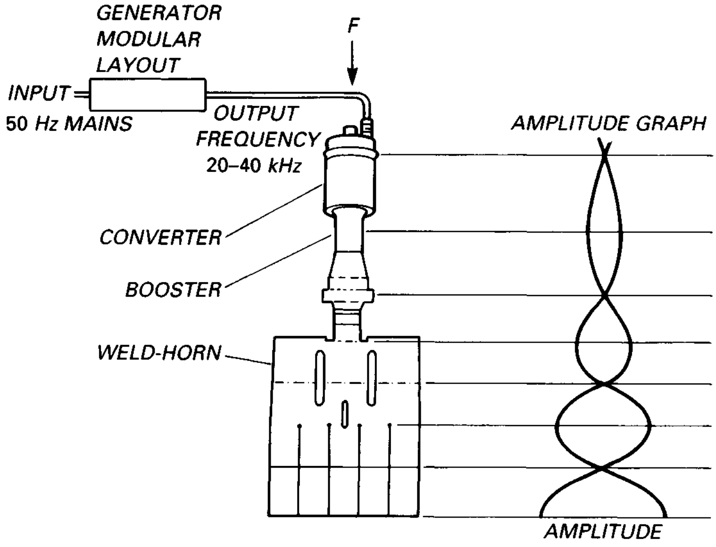
It will be noted that with hot plate and electric fusion methods of welding, no extra filling rods are required. The electric fusion jointing of pipes is more convenient than the hot plate method and is largely used today.

Ultrasonic welding

With this method of machine welding, an alternating current of frequency 50 Hz is connected to a generator where its frequency is changed to 20–40 kHz (20000–40000 Hz) the capacity of the generator being 100–3000 W as required (Fig. 8.14). This ultrasonic current, say at 20 kHz, is fed into a transducer (which is generally a piezo-electric device) which changes the ultrasonic electric vibrations into a mechanical vibration also at 20 kHz. (The magneto-strictive types are little used nowadays.)

A piezo-electric material increases in length when a current flows through a coil surrounding the device and changes the alternating electric field into mechanical movement. Examples of piezo-electric materials are quartz, tourmaline (a silicate of boron and aluminium with additions of

Fig. 8.14. Resonant unit, showing various amplitude gains in ultrasonic welding (piezo-electric crystal transducer) (Bielomatik).



magnesium iron and other alkaline metals and fluorine) and Rochelle salt (sodium potassium tartrate etc.). Present-day transducers have thin sheets or wafers of piezo-electric material bonded to a central metal laminated core while two metal strips are bonded to the other faces of the piezo-electric material, the lengths of these strips being about one half that of sound in the metal core, so that the assembly is resonant at the given frequency and vibrates ultrasonically at the frequency of the input current. The welding head to which the transducer is fixed is inserted to get the gain in amplitude which cannot be obtained from the horn alone. It consists of two parts: the booster and the horn, or tool holder. The booster increases the amplitude of the vibration and is clamped at its nodal point (the point of least vibration). If the booster has a larger diameter where it is attached to the transducer body than where it is attached to the horn, the amplitude is increased and the ratio of the masses of metal on each side of the node determines the increase or decrease of the vibration.

The horn is specially designed to have the correct sonic properties, and transmits pressure to the welded surfaces and vibrates to make the weld. It must have good mechanical strength; the end which makes the weld can be of cylindrical shape, bar shape, or more complex shapes according to the parts to be welded. The horn can be made of steel alloy, aluminium alloy or titanium, which all have good ultrasonic properties.

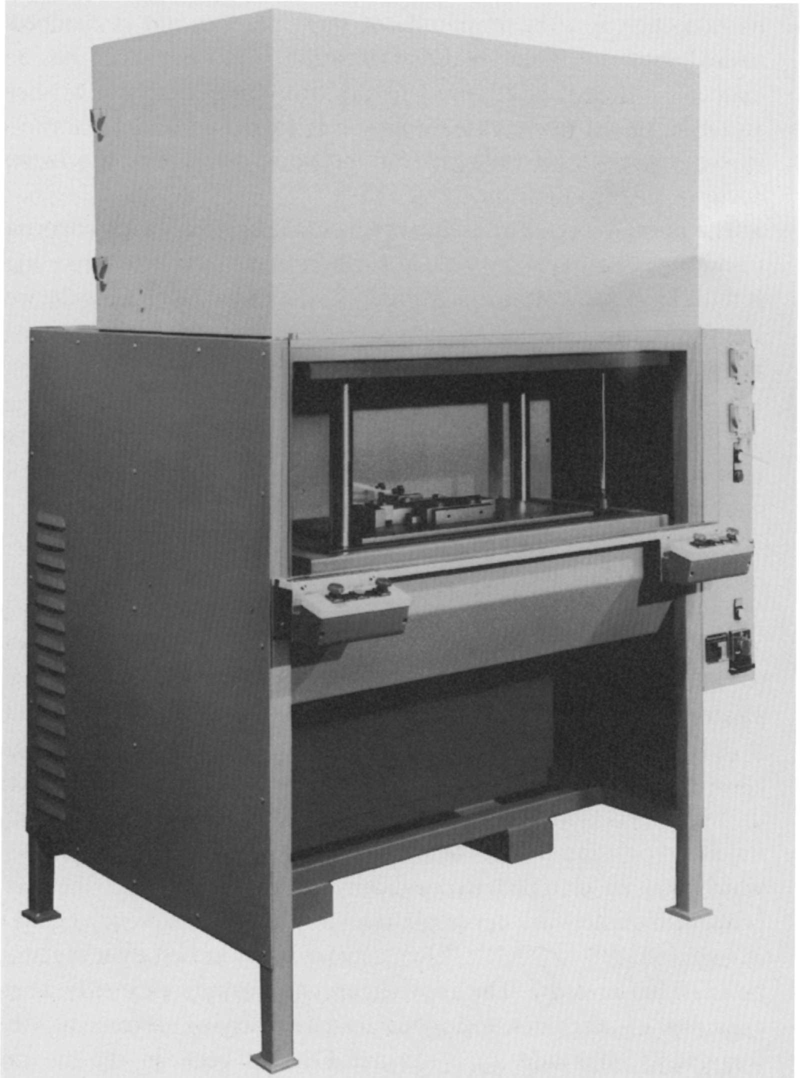
The sequence of operations is: (1) machine is loaded; (2) force is applied; (3) ultrasonic power flows for a given time; (4) hold time during cooling of the weld; (5) force is removed and machine deloaded.

Vibration welding (linear)

This method, which is mechanized (Fig. 8.15) has an upper plate (or platten) on which one of the parts to be welded is secured; the lower platten carries the other part to be welded. The upper platten is vibrated hydraulically and is connected to springs. The frequency of vibration (180–300 Hz) is infinitely adjustable, as is the amplitude of vibration (0–1.2 mm each way, i.e. 2.4 mm in total). When the plattens are in the unloaded position there is ample space between them to mount the parts, which can be clamped hydraulically if required. When the parts are brought together, the upper platten vibrates, the frequency being varied as required. When the parts are plasticized they are brought together with up to 60 bar pressure. The above figures are for reference only. Particular examples of machines will naturally have varying degrees of vibration frequency, amplitude and pressure. Friction between the moving and fixed parts generates the heat required for the welding process and the pressure assures good fusion. The pressure is time dependent and is reduced to a lower value for some of the welding time and the cooling time. The time cycle varies from 1 to 4 seconds in most cases.

This method is especially useful for welding thermoplastics of low

Fig. 8.15. Bielomatic linear vibration welding machine features a short amplitude and high frequency, enabling accurate welding of components even with very small clearances.



viscosity, such as various grades of nylon. It is evident that the machine is suitable for mass production of parts as there is considerable tooling required for each job. Plastics that have a low coefficient of friction, e.g. PTFE (polytetrafluorethylene), are not satisfactorily welded by this method.

Joining plastics and rubbers by means of adhesives

Plastics are being increasingly used by production engineers for stressed parts of assemblies. From the welding point of view plastics can also be joined by means of adhesives. To join surfaces together they should be completely cleaned and if possible roughened by rubbing down with fine sandpaper – metallic surfaces should be grit-blasted. The surfaces should not be touched after the final cleaning. The adhesive is then applied, enough being spread to ensure that any gaps which remain between the surfaces are filled with adhesive. The surfaces are then brought together and the adhesive soon becomes hard or 'cures': the higher the ambient temperature the quicker the cure. Also the thinner the line of bond between the surfaces, the greater will be the strength of joint and the more quickly will it cure. Slight irregularities of the surfaces increase both the grip and the locking effect.

One type of adhesive in use today is the 'instant' cyanoacrylate resin. These adhesives solidify because of the reaction between them and the thin layer of moisture always present on surfaces being bonded. The liquid adhesive is prevented from congealing when in its container, by the addition of an acidic stabilizer which keeps the molecules of the adhesive apart. On being applied to the surfaces being bonded the molecules of the stabilizer are repelled or removed and the molecules of the adhesive join together and curing commences. The 'instant' description of the resin indicates that the curing process is extremely short and can be just a second or so. Not all surfaces are suitable for successful bonding because they have insufficient attraction for the molecules of the adhesive and they must be treated with other preparations which prepare their surfaces for bonding. Surfaces of polyesters and ABS (acrylonitrile-butadiene-styrene) are examples of those with good attraction while others, such as polyethylene, have little attraction.

In the original acrylic resin adhesive, the smallest molecules are those of the methyl group of esters. The polymer chains of molecules are large in number, resulting in high tensile strength bonds. The ethyl group have larger molecules so that there are fewer on a given area than for methyl esters, with the result that there is a less rigid joint, but one suitable for bonding rubbers and plastics. In addition, the curing time is increased but with less odour.

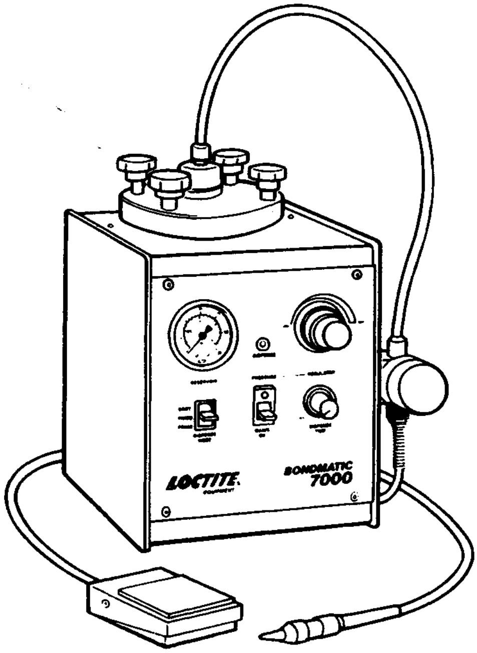
There is a wide range of adhesives covering most applications for locking threaded parts, for acidic and porous surfaces and those having great 'peel' strength with a top temperature of 100 °C and a tensile strength of 26 N/mm^2.

The 'gel' type adhesives are used for fabrics, paper, phenolics, PVC, neoprine, and nitrile rubber, with a curing time of a few seconds only. One gel has no associated fumes or odour and can be used in confined spaces, while another is clear and thick and does not run. Its top temperature is over 100 °C and it resists heat that would destroy a normal bond made with instant adhesive.

Another type is used for the assembly of pulleys, sprockets, bearings, bushes, sleeves etc., and other adhesives are used for pressed fits for cylinder liners of diesel engines. There are many other applications of this type. There is also a range of adhesives which bond the substrates of glass, ceramics, ferrites, epoxy moulding compounds, phenolic resins, laminated paper, and glass fibre laminate epoxy materials.

By the use of single-component liquids, drying rapidly at room

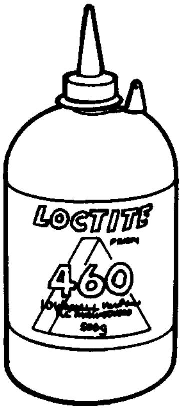
Fig. 8.16. Bondmatic® with foot switch and pencil.



temperature, surfaces are made suitable for bonding polyolefins and other low-energy surfaces. The liquid is applied by brush, spraying or dipping and is a polyolefin primer so that it should only be used for difficult-to-bond surfaces, e.g. polyolefins, polypropylene, PTFE and thermoplastic rubber.

With such a variety of adhesives available, each developed for a specific purpose, it is essential that the operator should contact the makers of the adhesives and obtain a full list of the adhesives available and their method of usage (Figs. 8.16 and 8.17).

Fig. 8.17. Loctite® adhesive squeeze bottle.



Some of the plastics considered with a few of their properties

Plastic	Properties
PVC (HDPVC and LDPVC)[a]	Low resistance to heat; rigid PVC higher. Low stress application, but up to 75 °C use HDPVC. Expansion 6–7 times that of steel. Low notch impact test, but this is improved by compounding with other substances. Expansion and contraction problems important when lining tanks or pipe-lines. Rigid PVC widely used for welding. Compounded with ABS, improves its impact strength, but chemical resistance suffers.
ABS (ABS/PVC and ABS/MAT: hard ABS reinforced with fibreglass, thermosetting)	Light, with high impact strength, good resistance to chemicals (alkalis and dilute acids). Used for radiator grilles, etc.

Plastic	Properties
Polypropylene (PPHD and PPLD)	Rigid and m.p. 170 °C. Low SG can be used up to 120 °C, has good mechanical strength and is resistant to most corrosive substances. Welded polypropylene can be used up to 120 °C as long as little stress is applied. Has replaced PVC and polythene in many fields. Used for sheeting, ropes and webbing. Compounded with other substances to improve qualities such as anti-cracking.
Polyethylene (Ethylene C_2H_4)	Soft and semi-flexible (makes squeeze bottles). Used for bags of all kinds. Similar in many ways to polypropylene. Used for pipes such as those used by British Gas which demand ease of connection and flexibility, for mains and smaller services. Used for injection moulded houseware (sink tidies, bowls etc.).
PTFE (Ethylene with four fluorine atoms substituted for hydrogen atoms)	Polytetrafluorethylene is mixed with other substances to give good heat resistance up to 200 °C and good dielectric properties. Welding temperatures 320–400 °C, low friction coefficient. Used for heat-resistant non-lubricated parts.
Polyacrylates (PMMA)	Polymethyl-methacrylate transmits about 92% light, has excellent optical properties and does not shatter. Chemical resistance only fair. Polyacrylates which are modified cannot be welded but can be cemented.
Polycarbonates	Low tendency to crystallize. High melting point, absorb little water, are tough and shock resistant. Yellowish or colourless. Can stand deformation but are soluble in some solvents such as methylene chloride. Resistance to chemicals rather low. Attacked by concentrated mineral acids, alkalis, ammonia, amines, ketones etc., and thus are used for dilute acids (organic and inorganic) mineral and vegetable oils and fats.
Polyamides	Contain amide group NHCO. Better known as nylon, certain types of which can be welded. Tough with high melting point. Resistant to oils, dilute acids and alkalis and some solvents. Used for textiles, hosiery, pipes, bearings and moulded parts where their higher melting point is an advantage. Some types absorb water others do not. Properties vary with the final composition.

[a] HD, high density; LD, low density.

Appendix 1

Welding symbols

A weld is indicated on a drawing by (1) a symbol (Fig. A1.1*a*) and (2) an arrow connected at an angle to a reference line usually drawn parallel to the bottom of the drawing (Fig. A1.1*b*). The side of the joint on which the arrow is placed is known as the 'arrow side' to differentiate it from the 'other side' (Fig. A1.1*c*). If the weld symbol is placed *below* the reference line, the weld face is on the *arrow-side* of the joint, while if the symbol is above the reference line the weld face is on the other side of the joint (Fig. A1.1*c*). Symbols on both sides of the reference line indicate welds to be made on both sides of the joint while if the symbol is across the reference line the weld is within the plane of the joint. A circle where arrow line meets reference line indicates that it should be a peripheral (all round) weld, while a blacked in flag at this point denotes an 'on site' weld (Fig. A1.1*d*). Intermittent runs of welding are indicated by figures denoting the welded portions, and figures in brackets the non-welded portions, after the symbol (Fig. A1.1*e*). A figure before the symbol for a fillet weld indicates the leg length. If the design throat thickness is to be included, the leg length is prefixed with the letter '*b*' and the throat thickness with the letter '*a*'. Unequal leg lengths have a × sign separating the dimensions (Fig. A1.1*f*). A fork at the end of the reference line with a number within it indicates the welding process to be employed (e.g. 131 is MIG, see Table A1.1) while a circle at this point containing the letters NDT indicates that non-destructive testing is required (Fig. A1.1*g*). Weld profiles, flat (or flush), convex and concave profiles are shown as supplementary symbols in Fig. A1.1*h*.

Figure A1.2*a* gives the elementary symbols and A1.2*b* typical uses of them. The student should study BS 499, Part 2, *Symbols for welding*, for a complete account of this subject.

Table A1.1 shows the numerical indication of processes complying with International Standard ISO 4063.

Appendix 2

Simplified notes on the operation of a thyristor

An ‘n’ type silicon wafer or element has impurities such as antimony, arsenic or phosphorus added to it to increase the number of negatively charged electrons available, termed ‘doping’.

A ‘p’ type has impurities such as indium, gallium or boron added to increase the number of positive carriers or ‘holes’ available.

Both types have increased conductivity compared with the pure silicon.

When ‘n’ and ‘p’ types are placed in contact this forms a diode (two elements) and this will pass a current in one direction but not in the other (subject to certain temperature considerations), converting the a.c. input into half-wave pulsating d.c. The electrons flow from the ‘n’ type where there are free electrons to the ‘p’ type where there are positive ‘holes’. By connecting four diodes in bridge connection full wave rectification is obtained (Figs. A2.1 and A2.2).

LOW POWER STUD BASE THYRISTOR

---

* Gallium arsenide is now regarded as a suitable material for integrated circuits (IC) and other devices, not supplanting silicon, but being used for high speed and high frequency applications where silicon is not suitable.

The thyristor (sometimes called the silicon controlled rectifier or SCR) has four elements with three junctions and a further terminal called the 'gate' which is connected to the 'p' layer adjacent to cathode (Fig. A2.1). If the gate is connected directly to the cathode, the device blocks the flow of current in either direction. However, if, while the anode is positive with respect to the cathode, the gate is also made positive (typically by two or three volts), current will flow from anode to cathode. The current required in the gate is usually between 1/100 and 1/1000 of the maximum anode current. Once conduction has been so initiated, the gate has no further effect, and can be de-energized. Conduction will continue until the external circuit causes the current to fall to zero, when the device will revert to its blocking state. Like a diode, it will not permit reverse (cathode to anode) current flow under any conditions.

If half the diodes in a bridge rectifier are replaced by thyristors (Fig. A2.2), and an adjustable time delay is incorporated in the circuit generating the gate current, the d.c. output of the bridge may be varied from zero up to the equivalent of an ordinary diode bridge, by varying the time delay.

Fig. A2.3 shows typical waveforms for half output. A diode bridge connected to the supply shown in Fig. A2.3(*a*) would produce a d.c. output voltage as in (*b*). However, by using thyristors and delaying the firing pulses by a quarter of a cycle after the thyristor anodes become positive, the output voltage is halved. Fig. A2.3(*c*) shows the gate pulse timing, and (*d*) the resultant d.c. voltage.

Fig. A2.2 also shows, in simplified form, automatic control of this firing delay. The desired current is set by a single control knob on potentiometer *C*. This is compared electronically with the measured value of current from sensor *H* and the pulse timing adjusted automatically to maintain the current at the set level.

Fig. A2.2 Simplified schematic diagram for one knob control of welding current by thyristor (SCR).

Appendix 3

Proprietary gases and mixtures

Cylinder colour identification

Gases and gas mixtures are identified by colours as recommended in BS 349, 1973. The contents of the cylinder are indicated by the name(s) and chemical formula(e) on a label on the shoulder of the cylinder. Secondary identification is by the use of recommended base colours on the body of the cylinder and coloured bands on the cylinder to indicate the type of gas.

Gas	Cylinder colour
Acetylene	Maroon
Air (not breathing quality)	Grey
Argon	Blue
Carbon dioxide, commercial vapour withdrawal	Black
Carbon dioxide, commercial liquid withdrawal	Black with white stripes down length of cylinder
Hydrogen	Red
Nitrogen	Grey with black shoulder
Oxygen	Black
Propane	Red, wider and shorter cylinder
Argon/carbon dioxide	Blue, green band on cylinder
Argon/helium	Blue, green band on shoulder
Argon/hydrogen	Blue, red band on shoulder
Argon/oxygen	Blue, black band on shoulder
Nitrogen/hydrogen	Grey with red band or red with grey band

AGA GAS Ltd. Selection of gases

Gas	Cylinder contents	Applications
Argon	Ar 99.99 %	TIG, MIG (GTAW, GMAW) and plasma welding, root purging. Nickel based alloys and high alloy steels (stainless steel). Copper and its alloys
Helium	He	Aluminium welding with a.c. and also straight polarity d.c. (d.c.e.n.)
AGA MIX® UN	Ar 80 %, CO_2 20 %	MAG (GMAW) welding mild and low alloy steel
AGA MIX® ST	Ar 98 %, CO_2 2 %	MIG, MAG (GMAW) welding stainless and low alloy steel. Not low carbon stainless steel
AGA MIX® SP	Ar 92 %, CO_2 8 %	MAG welding low alloy steel and mild steel, mainly spray and pulse
AGA MIX® SH	Ar 75 %, CO_2 25 %	MAG welding mild and low alloy steel, mainly short arc
AGA MIX® O_2	Ar 98 %, O_2 2 %	MAG welding stainless steel not less than 0.03 % C. Mainly for spray arc
AGA MIX® H5	Ar 95 %, H_2 5 %	Plasma cutting
AGA MIX® H20	Ar 80 %, H_2 20 %	Plasma cutting
AGA MIX® H35	Ar 65 %, H_2 35 %	Plasma cutting
AGA MIX® He30	Ar 70 %, He 30 %	Welding copper and its alloys
AGA MIX® He70	Ar 30 %, He 70 %	Welding copper and its alloys and titanium
AGA MIX® N_2	Ar 98 %, N 2 %	Welding duplex stainless steels
AGA MISON®	Ar with less than 0.03 % NO	In every case where argon is indicated
AGA MIX® NH	H_2 10 %, N_2 90 %	Used as root protection when welding stainless steel
Argon + (pure)		Welding titanium
Nitrogen	N_2	Gas purging. Plasma cutting

Gases marked ® are trade names of AGA GAS Ltd.

Industrial gases and mixtures supplied by Air Products plc

Name	Cylinder contents	Cylinder colours	Applications
Oxygen	O_2	Black	
Nitrogen	N_2	Grey with black shoulder	
Helium	He	Brown	
Argon	Ar	Peacock blue	
Hydrogen	H_2	Red	
Coogar® 5	Ar 93%, CO_2 5%, O_2 2%	Peacock blue with pastel purple shoulder and contents stencilled in black	MIG/MAG welding of steel 10 mm thick and below
Coogar® 20	Ar 78%, CO_2 20%, O_2 2%		MIG/MAG welding of steel 10 mm thick and above
Coogar® SG	Ar 83%, CO_2 15%, O_2 2%		Synergic pulse and standard MIG/MAG welding of steels, all thicknesses and positions
Astec® 15	He 75%, Ar 23.5%, CO_2 1.5%	Pale blue with contents stencilled in black	MIG/MAG welding of low alloy steels and austenitic stainless steels with dip transfer
Astec® S3	He 35%, Ar 63%, CO_2 2%		Synergic pulse and standard MIG/MAG for high quality welds in stainless steels
Astec® 25	He 75%, Ar 25%		MIG and TIG applications on high thermal conductivity – non-ferrous metals
Astec® 30	He 30%, Ar 70%		MIG and TIG applications on high thermal conductivity – non-ferrous metals
Astec® 50	He 50%, Ar 50%		MIG/MAG and synergic pulse weld overlay/surfacing applications

Quasar®	Ar 98%, O_2 2%	Supplied in liquid form by Minitank	MIG/MAG welding of steels and stainless steels, recommended for use with robotics or automatic applications on thinner section metals
Hytec® 1	Ar 99%, H_2 1%	Pastel purple with red shoulder and contents stencilled in black	Manual TIG applications on stainless steel
Hytec® 3	Ar 97%, H_2 3%		Manual TIG applications on stainless steel
Hytec® 5	Ar 95%, H_2 5%		Automatic and orbital TIG, plasma welding
Hytec® 35	Ar 65%, H_2 35%		High quality plasma cutting of stainless steel, aluminium and nickel alloys
Acetylene	C_2H_2	Maroon	Oxy-acetylene cutting, brazing and welding applications
Apachi-plus®	C_3H_8	Orange with red neck	Fuel gas for cutting, brazing and thermal spraying applications
Propane	C_4H_{10}	Red with green neck	Heating and cutting

BOC Ltd (British Oxygen Co Ltd): Shieldmaster range of gases for welding and cutting

Gas		Cylinder contents	Cylinder colours	Applications
Oxygen	h[a]	Oxygen O_2 (99.7% purity)	Black	
Nitrogen	l[b]	Nitrogen N_2 (99.99% or 99.999% purity)	Grey with black shoulder; two white circles on shoulder indicate the higher purity	
Helium	l	Helium He	Brown	
Argon	h	Pure argon Ar (99.997% purity)	Blue	
		High purity argon (99.999% purity)	Blue plus a certificate of quality	
Carbon dioxide	l	Carbon dioxide CO_2 (to BS 4105 99.8% purity)	Vapour withdrawal black; liquid withdrawal black with two vertical white stripes, full length of the cylinder	
Argoshield® 5	h	Ar 93%, CO_2 5%, O_2 2%	Blue with green band round middle of cylinder and green shoulder; individual gases denoted by shoulder label and identity disc round neck	GMA/MIG welding thin mild steel sections (dip transfer) up to 3 mm thick
Argoshield® TC	h	Ar 86%, CO_2 12%, O_2 2%		GMA/MIG welding mild steel (dip and spray transfer) 3–10 mm thick; mini MIG welding mild steel
Argoshield® 20	h	Ar 78%, CO_2 20%, O_2 2%		GMA/MIG welding mild steel (spray transfer) above 10 mm thick
Pureshield® P1		Ar 98.5%, H_2 1.5%	Blue with red band round middle of cylinder; identity disc round neck; applications and identity label above red band	GTA/TIG welding austenitic stainless steel
Pureshield® P2		Ar 65%, H_2 35%		Plasma cutting aluminium and stainless steel
Helishield® H1	l	He 83%, Ar 15%, CO_2 2% and a trace of oxygen	Brown with blue band round middle of cylinder; identity disc round neck; applications and identity label above blue band	GMA/MIG welding stainless steel – dip transfer
Helishield® H2	l	He 75%, Ar 25%		GMA/MIG and GTA/TIG welding copper and thicker sections of aluminium
Helishield® H3	h	He 30%, Ar 70%		GMA/MIG and GTA/TIG welding aluminium and aluminium alloys
Helishield® H5	l	He 50%, Ar 50%		GMA/MIG and GTA/TIG welding nickel and nickel alloys
Helishield® H101	l	He 40%, Ar 60% plus some CO_2		GMA/MIG welding stainless steel, low alloy steel; spray transfer
Argomix®	h	Ar 80%, CO_2 20%	Blue with green band round middle of cylinder	Special applications of GMA/MIG welding mild steel; spray transfer
Argon/Hydrogen	l	Special mixtures as required	Blue with red band round middle of cylinder	Special GTA/TIG welding applications
Argonox®	h	99/1, 98/2, 95/5% argon/oxygen	Blue with black band round middle of cylinder	GMA/MIG welding stainless and high alloy steels
Acetylene	l	Acetylene C_2H_2	Maroon	Bevelling, high speed flame cutting and welding mild steel; brazing
Propylene	h	Propylene C_3H_6	Red body, pink top and bottom	Metal spraying
Propane	h	Propane C_3H_8 to BS 4250	Red	Flame cutting mild steel; pre-heating

[a] h – heavier than air.

[b] l – lighter than air.

Gases marked ® are trade names of BOC Ltd.

Note GMA (gas metal arc) is the American term for MTG); GTA (gas tungsten arc) is the American term for TIG.

Manifolded cylinder pallet (MCP) contains 15 N size cylinders connected to a single outlet. The N cylinder is usually 200 bar pressure as is the MCP manifold.

Distillers AG Ltd: gases for welding and cutting

Gas or gas mixture	Cylinder contents			Cylinder colours	Applications
Oxygen	O_2			Black	Welding and cutting
Nitrogen	N_2			Grey, with black shoulder and guard	Freezing, purging, certain steels, plasma cutting
Helium	He			Brown cylinder, shoulder and guard	TIG welding of non-ferrous metals and alloys. General TIG applications
Argon	Ar			Peacock blue	Non-toxic, smooth arc, easy start, little spatter. Used in MIG and TIG welding and in gas mixtures
Hydrogen	H_2			Red cylinder, shoulder and guard	MAG welding of stainless steel. Very inflammable
Carbon dioxide	CO_2			Black with white stripe down cylinder length. For commercial liquid withdrawal	Sometimes used on its own for welding. Also mixed with other gases (see below)
Propane	C_3H_8			Red cylinder with valve core blue	For cutting and heating when used with oxygen
Acetylene	C_2H_2			Maroon	Welding and cutting
Air (blended)	Air			Grey cylinder and cage	Cutting
Argon and argon-based					
	Ar	CO_2	O_2		
Krysal® 5	93%	5%	2%	Peacock blue, with pink shoulder and guard	Thin low carbon steel. Low spatter, pulse arc. All positions
Krysal® 20	78%	20%	2%	Peacock blue, with pink shoulder and guard	Thick low carbon steel. Reduced spatter. Not suitable for pulse

Krysal® SM	85%	13.5%	1.5%	Peacock blue, with pink shoulder and guard	Most sections low carbon steel. Smooth arc. Minimum spatter. Suitable pulse arc and has robotic uses
Krysal® G8	92%	8%	—	Peacock blue with pink shoulder and guard	CO_2 component controls penetration and bead shape for weld strength. Improves wetting and viscosity
Krysal® 155	80%	15%	5%	Peacock blue, with pink shoulder and guard	The oxygen content stabilizes the arc, improves wetting and gives good fusion
Excellar® 8	Argon-based			Bulk liquid form	Developed for MAG welding of carbon steels and good for automatic operations
Argon–oxygen					
	Ar	O_2			
Argon/oxygen 1%	99%	1%		Blue, with black shoulder; contents stencilled in black	Used for the MIG and MMA welding for stainless steel. Reasonable spatter
Argon/oxygen 2%	98%	2%			
Argon/oxygen 3%	97%	3%			
Helium based					
	Ar	He	CO_2		
Stellar® 30	70%	30%	—	Mid-brown with pink shoulder and guard	Used when argon–hydrogen is inappropriate. Deep penetration. As the helium percentage rises the arc becomes less stable. Higher helium mixtures are ideal for non-automated processes. For MIG welding of non-ferrous metals, aluminium, copper etc. TIG welding of most materials. Stellar 50 and Stellar 75 are lighter than air
Stellar® 50	50%	50%	—		
Stellar® 75	25%	75%	—		

Gas or gas mixture	Cylinder contents			Cylinder colours	Applications
Stellar® T1	minor	major	trace	Mid-brown with pink shoulder and guard	For MAG welding of stainless steels. T1 and T6 are lighter than air
Stellar® T6	major	minor	trace		
Stellar® T8	major	minor	trace		
Helihi®	Helium–air			Cylinder body brown, cage pink	Balloon gas
Argon–hydrogen					
	Ar	H_2			
Hylar® 1	99%	1%		Peacock blue, with signal red shoulder and pink guard	For TIG welding of stainless steels
Hylar® 2	98%	2%			
Hylar® 3	97.5	1.5%			
Hylar® 5	95%	5%			
Hylar® 35	65%	35%			
Shielding gases for plasma welding					
Argon					Used both as orifice and shielding gas with some equipment.
Hylar® 5					Used as a shielding gas for plasma welding thin material.
Hylar® 35					Used for plasma cutting in certain applications

Mixtures of gases containing more than 5% hydrogen can be explosive.

Argon is non-toxic, but both argon and carbon dioxide are asphyxiants in high concentrations. Carbon dioxide dissociates in the arc; the oxygen produced increases wetting. The occupational exposure standard (OES) has been set at 5000 vpm. Carbon dioxide in the atmosphere is approximately 350 vpm.

A toxic gas is one that in its pure form has an OES as defined by the Health and Safety Executive of less than 500 vpm.

Gases marked ® are trade names of Distillers AG Ltd.

Appendix 4

Tests for wear-resistant surfaces

The following tests for wear are used

(1) *Adhesive wear test* in which a test specimen in the form of a block is pressed or loaded against a rotating alloy wear test specimen in the form of a ring or of a comparison standard. The block and ring may be of similar or dissimilar alloy and the ring may be lubricated (optional). The volume loss for various loads is measured for a given number of revolutions.

(2) *Abrasive wear test* in which dry sand is fed between the surfaces of a wear test specimen which is pressed or loaded against a rotating rubber wheel. The volume loss of the specimen for a given number of revolutions and load is measured.

(3) *Galling test* in which a rotating cylindrical pin made from undiluted weld metal (e.g. TIG) is pressed (loaded) against a standard ground block and the stress in kg/mm^2 at which visual sign of material transfer (galling) occurs after one revolution of the pin is noted.

Appendix 6

Low hydrogen electrode, downhill pipe welding

A d.c. power source is used as with cellulosic rods (p. 73) and is usually engine driven in the field, the electrode being connected to the – ve pole. Weld metal deposition is faster than with cellulosic or uphill low hydrogen methods and a short arc is used with no 'pumping' of the electrode. Since shrinkage is important, if internal clamps are used there should be more spacers. The preparation of a joint using different diameter pipes is show in Fig. A6.1 and the tack welds should be tapered at each end.

For the root run the electrode should lightly touch the joint and the weld should continue through 6 o'clock about 2 mm towards 7 o'clock to facilitate link up with the run to be deposited on the other side. There is no weave and keeping a short arc and high travel rate the slag is kept above the

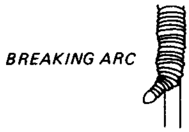
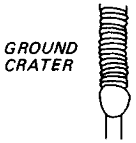
Fig. A6.2



BREAKING ARC

Fig. A6.3



GROUND
CRATER

arc at a distance of about the coating diameter. The arc is broken by turning into the bevels and the metal is tailed off as shown in Fig. A6.2.

The finishing crater should be ground to a pear-shaped taper (Fig. A6.3) and the next electrode is started about 10 mm above the top end of the tapered crater. Slag is removed from each run with power brush and chipping hammer and grinding is used to remove any excess metal generally from 4 to 6 o'clock. The penetration bead may be slightly concave but has a smooth tie-in with the pipe metal and is acceptable. Too much heat gives increasingly convex penetration and is due to too slow travel or too high a current.

Avoid burn through between 12 and 1 o'clock when using a leading arc by keeping the arc as short as possible and directing it alternately to each side of the joint. Fig A6.4 shows angles of electrode, electrode diameters and currents.

For the filling and capping runs the arc is kept short with a weave not exceeding 3 to 4 times the core wire diameter and the slag–electrode distance

during use and the joint should be completely free of all moisture. The weld metal has high resistance to cracking and is of composition C 0.06–0.09%, Mn 1.00–1.40%, Si 0.03–0.07% and classification AWS A5.5 E8018-G BS 639 E5154B 120 90(H).

Appendix 7

The manufacture of extruded MMA electrodes

As previously stated, almost all electrodes are produced by the extrusion process. The present day electrode consists of a core wire, centrally placed in a coating, usually silicate bonded (Vol. 1, p. 60). Double coated electrodes are also produced.

A semi-automatic production line may consist of the following:

(1) *Wire drawing.* Non-slip hydraulic machines draw the wire through dies to the correct size, after which the wire is stored on reels.

(2) *Wire cutting.* The wire is then straightened and cut to electrode length, giving burr-free wire rods of any required length which are stacked in bins.

(3) *The coating.* The raw materials of the coatings are kept in raw material silos and from these the materials are sieved and dosed. It is the type and composition of these materials that determines the characteristic of the particular electrode. The dosing installations consist of a number of silos each fitted with a discharge system, dosing control and weighing facilities.

(4) *Silicate storing* consists of tanks that are temperature controlled and from which the silicate is pumped to the mixer.

(5) *Dry blending and wet mixing.* The batch is first thoroughly mixed in the dry state and then a measured quantity of silicate is added from a dosing unit. The wetted batch is then roughly mixed, emptied and removed to the slug press, where it is pressed into slugs ready for extrusion.

(6) *Extrusion.* The slugs are placed into the charging trough and when this is full the load of slugs is thrust into the extrusion cylinder. The breech of the hydraulic extrusion cylinder is then locked by a simple lever movement. The cut and deburred wires are stored adjacent to the wire feed from which, by opening a slide in the bin

side, the wire rods drop into the feed magazine. The extruder piston is then operated and when the flux flow pressure is reached the wire feed commences. Accelerator and drive rolls take the rods dropping from the magazine and push them axially through the press to the extrusion head where they receive their coating.

(7) *Concentricity check and brushing.* It is important that the core wire should be centrally placed in the covering (pp. 5–6). This is checked electronically and adjustments made if required. A transfer belt then takes the electrodes to a brushing station where the ends for the electrode holder and the striking tip are formed, after which the number or type of electrode is printed on the coating by a printing machine.

(8) *Drying and baking.* The electrodes are air dried to prevent cracking of the coating and are then loaded into baking ovens, after which they are ready for packing.

Where high capacity is required, two extruders are placed in parallel. When one is being charged the other is working, so that the same brushing and drying ovens are used and delay in production is minimised. In many cases the high speed wire drawing and cutting machines are fully automatic and the drying ovens are of the bucket type with conveyor chains up to 1000 m long and temperatures up to 450 °C.

Appendix 8

Notes on fire extinguishing (BS 5306, Part 3: Code of practice for selection, installation and maintenance of portable fire extinguishers)

For a fire to occur we need *oxygen, fuel* and *heat.*

Oxygen is present in the atmosphere and in the compressed form contained in cylinders used for oxy-acetylene or oxy-propane cutting.

Fuel may be any combustible substance such as petrol, diesel oil, paper, cleaning materials, rubber or litter etc. – anything that will burn.

Heat may be supplied by discarded cigarette ends, match sticks and, in the welding shop, by sparks from the arc or bad connections such as those at the earth or return terminal to the set. The arc is an intense source of heat and, together with the sparking, will rapidly cause ignition of any combustible solids or liquids in the immediate vicinity.

If any one of these above causes is removed, the fire will be contained. For example the oxygen supply from the atmosphere may be contained by smothering the fire with a blanket or dry sand or by turning off the oxygen supply if it is from a cylinder. The heat can be controlled by ceasing to use the arc and switching off all power supplies to prevent further arcing at poor contacts.

Classes of fire with suitable extinguishing media

(*A*) Solid materials (carbonaceous fires forming glowing embers). Use water type extinguisher (cooling method) except on electrical apparatus.

(*B*) Liquids or liquifiable solids (petrol, paraffin, wax, etc.). Use foam, dry powder, CO_2, vaporizing liquid, fire blanket, dry sand. (smothering method).

(*C*) Flammable gases, liquid petroleum gas including propane and butane, acetylene. Turn off the supply (starvation method).

(*D*) Metals (magnesium, metallic powders). Special powders containing sodium or potassium chloride are required. Such fires should be dealt with by the fire brigade.

Types of extinguishers

(1) *Carbon dioxide CO_2.* This contains liquid CO_2 under pressure, which is released as a gas when the trigger or plunger on the extinguisher is operated.
(2) *Extinguishing powder (gas cartridge).* The powder is expelled by the pressure from a gas cartridge.
(3) *Extinguishing powder (stored pressure).* The powder is expelled by pressure stored within the body of the extinguisher.
(4) *Foam (chemical).* Chemicals stored in the body of the extinguisher are allowed to mix and react, producing foam, which is expelled from the extinguisher.
(5) *Foam (gas cartridge).* Foam is expelled from the extinguisher by the pressure from a gas cartridge.
(6) *Foam (mechanical stored pressure).* Pressure stored in the body of the extinguisher expels the foam.
(7) *Halon (stored pressure).* The body of the extinguisher contains a halon which is expelled by pressure stored within the body.
(8) *Water (gas cartridge).* Water is expelled from the extinguisher by the pressure from a gas cartridge.
(9) *Water (stored pressure).* Water is expelled by pressure stored within the extinguisher body.
(10) *Water (soda-acid).* An acid–alkaline reaction within the body produces the pressure to expel the water.

Extinguishers containing dry powder, CO_2 and vaporizing liquids

These extinguishers are suitable for fires involving flammable liquids and live electrical apparatus (as are met with under welding conditions). For fires in liquids (containers or spillage) the jet or horn should be directed at the near side of the fire, which should be driven away from the operator to the far side with a side-to-side motion of the jet. If falling liquid is alight begin at the bottom and move upwards. On electrical apparatus direct the jet directly at the fire after first switching off the mains supply. If the latter is not possible, contain the fire and summon the fire brigade.

If there is no shut-off valve on the extinguisher continue discharging it over the fire area until empty. If the discharge is controlled, shut off the extinguisher discharge when the fire is extinguished and hold it ready for any further outbreak which may occur when the atmosphere has cleared.

Do not use vaporizing liquid extinguishers in confined spaces where there is poor ventilation and a danger of fumes being inhaled.

Foam extinguishers give semi-permanent protection against contained fires and will partially extinguish a fire, which will not gain its full intensity until the foam covering is destroyed. They may be used on liquids, in tanks to protect them from ignition or from giving off flammable vapours. Dry powder and foam should not be used together unless a specially compatible powder/foam are used.

BCF extinguishers

When this type is used the bromochlorodifluoromethane, which is a stable compound, appears as a heavy mist that blankets the fire and excludes the atmospheric oxygen. It is more efficient than chlorobromomethane (CB), methyl bromide (MB) or carbon tetrachloride (CTC). It does not damage normal materials and leaves no deposit. It decomposes slightly in the heat of a flame but the amount of harmful gas produced (which has a pungent smell) has no effect on adjacent personnel even when excess BCF is used. It has high insulating properties and can be used on electrical equipment and is particularly suitable for the welding or fabrication shop since it can be used on Class *A* fires in addition to those of Class *B* and *C*.

Fire prevention where welding processes are involved

General precautions

(1) All areas must be free of litter and combustible waste with all combustible material stored in metal bins, with lids, well away from the welding processes.

(2) Make certain that all electrical cables are not chafing and connections are secure and will not cause arcing. This applies particularly to the earth or return connection to the welding set.

(3) All chemicals including cleaning fluids should be kept away from the welding area, in a store room.

(4) Oxygen cylinders should be kept in a room apart from fuel gases such as acetylene and propane (LPG), which should be kept in another room. All cylinders and manifolds should be turned off except when in use. Keep cylinder keys with the appropriate cylinders in case of urgent need.

(5) No smoking signs should be prominently displayed and should be strictly adhered to.

(6) Defects in plant and equipment should be reported at once and indicated. Faulty electrical equipment is always a fire hazard.

(7) Always read the instructions for operation of the extinguisher situated in your shop.

Notes on procedures to be followed when using welding apparatus

Leakage of oxygen, as for example from a cylinder used in the cutting process, may lead to the ignition of any glowing or red-hot material due to the rapid oxidizing action of the escaping oxygen. The gas must be turned off at the cylinder valve (leave the cylinder key attached to the cylinder so that it is never misplaced). Remember that should flames play on a cylinder containing oxygen, there is a danger of explosion due to the high pressure involved – although oxygen is non-combustible it is a powerful supporter of combustion and may cause re-ignition.

Fuel gas cylinders

LPG, acetylene, etc. and accompanying apparatus and appliances

(1) Gas leak on fire. If the fire is away from regulators and cylinders first turn off the gas supply at the cylinder or appliance valve. If this is not possible and the fire is spreading to nearby combustible material, extinguish the flames and then seal the leak, taking care that re-ignition is not possible.

If the gas is on fire near a regulator or cylinder valve first extinguish the flames if this is possible within two or three minutes of the beginning of the combustion and use a cloth or gloves (e.g. welders) to turn off the valve and guard against re-ignition.

If the valve cannot be shut, evacuate the area and call the fire brigade.

If the gas is on fire and the flames are impinging on the gas cylinders, first extinguish the flames if this is possible within two to three minutes of the conflagration. If this is not possible, divert the flames from the affected cylinder away from the other cylinders and combustible material, evacuate the area and call the fire brigade.

Any cylinders exposed to the heat of fire should be removed within 2–3 minutes. If this is not possible, evacuate the area and call the fire brigade.

A burning gas leak can be extinguished by a dry powder, BCF or water type fire extinguisher in this order of preference but small fires may be smothered with a wet blanket or cloth.

A water type fire extinguisher should be used on any adjacent burning material and whilst dry powder or BCF types can be used in this case they will have only a limited effect.

Do not continue to fight a fire if there is a danger of gas cylinders exploding or if the fire continues to grow in spite of your efforts to contain it. Remember that extinguishers are only intended to deal with small fires so that the quicker the extinguisher is brought into use the better as fires spread quickly. Position yourself between the fire and the exit from the shop so that your escape will not be cut off.

If there is any possibility of the conflagration getting out of control in the slightest degree, call the Fire Brigade whose personnel are trained in fire fighting. They must be met on arrival and the officer in charge advised of the presence and position of all gas cylinders.

(2) Gas leak. No fire.

(*a*) The danger is from an explosion if the fuel gas is ignited. Keep all sources of ignition away from the gas. Do not smoke, switch on electric lights, electrical apparatus or telephones, etc. and do not drive vehicles in the vicinity.

(*b*) Shut off the cylinder valve or pipeline. If this is impossible move the cylinder(s) to the open air so as to dissipate the gas.

(*c*) Do not re-occupy the shops until they are properly ventilated and pay attention to pockets of gas that may exist in ducting, sumps and pits and see that they are completely purged.

Appendix 9

Table of brazing alloys and fluxes

General purpose silver brazing alloys: cadmium bearing

Description	Nominal composition	Melting range (°C)		BS 1845	Remarks
		Solidus	Liquidus		
Easy-flo	50% Ag:Cu:Cd:Zn	620	630	AG1	Cadmium-bearing alloys generally offer the best combination of melting range, flow characteristics and mechanical properties. Thus, where the presence of cadmium is acceptable, they would normally be recommended as the most economical alloys. Easy-flo, Easy-flo No. 2 and DIN Argo-flo are the lowest melting point alloys available. All three alloys have excellent flow characteristics. The highest joint strengths are obtained with Easy-flo. Alloys with 30–40% silver are normally considered as general-purpose alloys. They still offer good flow characteristics and melting ranges and are suitable for mechanized brazing operations. The low silver alloys have good fillet-forming characteristics and are widely used in fabricating brass fittings and furniture. Owing to their wide melting ranges they are not generally used as preforms due to the danger of liquation.
Easy-flo No. 2	42% Ag:Cu:Cd:Zn	608	617	AG2	
DIN Argo-flo	40% Ag:Cu:Cd:Zn	595	630	—	
Argo-flo	38% Ag:Cu:Cd:Zn	608	655	—	
Mattibraze 34	34% Ag:Cu:Cd:Zn	612	668	AG11	
Argo-swift	30% Ag:Cu:Cd:Zn	607	685	AG12	
Metalflo	25% Ag:Cu:Cd:Zn:Si	606	720	—	
Argo-bond	23% Ag:Cu:Cd:Zn	616	735	—	
Metalsil	20% Ag:Cu:Cd:Zn:Si	603	766	—	
Metalbond	17% Ag:Cu:Cd:Zn:Si	610	782	—	
Metaloy	13% Ag:Cu:Cd:Zn:Si	605	795	—	

General purpose silver brazing alloys: cadmium free

Description	Nominal composition	Melting range (°C)		BS 1845	Remarks
		Solidus	Liquidus		
Silver-flo 55	55% Ag:Cu:Zn:Sn	630	660	AG14	The range of cadmium-free alloys has been developed for applications where the presence of cadmium is not allowed due to the brazing environment or the service conditions of the assembly, i.e. food-handling equipment. Silver-flo 55 is the lowest melting-point alloy in the group and has been widely adopted as a substitute for Easy-flo No. 2. Silver-flos 30 to 45 are general-purpose alloys suitable for use on most common engineering materials. The alloys with less than 24% silver are widely used on copper and steel. They give a good colour match on brass, but require close temperature control due to their high melting temperature. Unlike the cadmium-bearing range, this group contains low silver content alloys such as Silver-flo 33, 24 and 16, with relatively high melting points, which make them ideal for step brazing.
Silver-flo 55	45%Ag:Cu:Zn:Sn	640	680	—	
Silver-flo 452	45%Ag:Cu:Zn:Sn	640	680	—	
Silver-flo 45	45% Ag:Cu:Zn	680	700	—	
Silver-flo 44	44%Ag:Cu:Zn	675	735	—	
Silver-flo 40	40%Ag:Cu:Zn:Sn	650	710	AG20	
Silver-flo 38	38% Ag:Cu:Zn:Sn	660	720	—	
Silver-flo 34	34%Ag:Cu:Zn:Sn	630	740	—	
Silver-flo 33	33%Ag:Cu:Zn	700	740	—	
Silver-flo 302	30%Ag:Cu:Zn:Sn	665	755	AG21	
Silver-flo 30	30%Ag:Cu:Zn	695	770	—

Silver-flo 1	1% Ag:Cu:Zn:Si	880	890	—	

General purpose silver brazing alloys: phosphorus bearing

		Melting range (°C)			
Description	Nominal composition	Solidus	Liquidus	BS 1845	Remarks
Sil-fos	15% Ag:Cu:P	644	700**	CP1	These alloys are recommended for fluxless brazing of copper. They may also be used on brass and bronze with the application of Easy-flo Flux or Tenacity 4A Flux. They should not be used on ferrous- or nickel-base materials or nickel-bearing copper alloys. The silver bearing alloys are more ductile than the Copper-flos and are recommended where joints will be subjected to significant stress levels.
Sil-fos 5	5% Ag:Cu:P	650	710**	CP4	
Silbralloy	2% Ag:Cu:P	644	740**	CP2	
Copper-flo	7% P:Cu	714	800	CP3	
Copper-flo No. 2	6% P:Sb:Cu	690	800	CP5	
Copper-flo No. 3	6% P:Cu	714	850	CP6	

** A small percentage of higher melting point material remains at this temperature.

Silver brazing alloys for tungsten carbide

		Melting range (°C)			
Description	Nominal composition	Solidus	Liquidus	BS 1845	Remarks
Easy-flo No. 3	50% Ag:Cu:Zn:Cd:Ni	634	656	AG9	General-purpose cadmium-containing alloy with excellent mechanical properties.
Argo-braze 38	38% Ag:Cu:Zn:Cd:Ni	615	655	—	An economical alternative to Easy-Flo No. 3 which has proved adequate for many applications.
Argo-braze 49H	49% Ag:Cu:Zn:Ni:Mn	680	705	—	A cadmium-free alternative to Easy-flo No. 3. The addition of manganese enhances wetting on difficult carbides.
Argo-braze 49LM	49% Ag:Cu:Zn:Ni:Mn	670	710	—	A free-flowing alloy giving good wetting. Suitable for small carbides.
Argo-braze 40	40% Ag:Cu:Zn:Ni	670	780	—	Economical alloys with good wetting characteristics. Their application is restricted by their relatively high melting points.
Argo-braze 25	25% Ag:Cu:Zn:Ni:Mn	710	810	—	
Easy-flo Tri-foil 'C'	Easy-flo bonded to both sides of a copper shim	620	630	—	For brazing large pieces of cemented carbide. The copper ensures that a thick stress-absorbing joint is achieved.
Easy-flo Tri-foil 'CN'	Easy-flo bonded to both sides of a copper-nickel shim	620	630	—	Recommended for joints subjected to high compressive stresses during service.
AB49 Tri-foil	Argo-braze 49LM bonded to both sides of a copper shim	670	710	—	A cadmium-free alternative to Easy-flo Tri-foil 'C'.

Brazing fluxes

Fluxes are normally selected on the basis of two main criteria: 1. The melting range of the brazing alloy – both solidus and liquidus should fall well within the quoted working range of the flux. 2. The parent metals to be joined – some alloys, such as aluminium bronze, require special fluxes. Copper, brass and mild steel are effectively cleaned by all fluxes.

Description	Working range °C	DIN 8511	Availability	Remarks	Residue removal
Easy-flo Flux	550–800	F-SH1	Powder/Paste	A general-purpose flux with good fluxing activity and long life at temperature. The powder has good hot-rodding characteristics.	
Easy-flo Flux Dipping Grade	550–775	F-SH1	Paste	A highly active and fluid flux which exhibits a minimum of bubbling, making it ideal for induction brazing. This paste is formulated to give a thin, stable consistency suitable for dipping.	Residues are generally soluble in hot water. Where difficulty is encountered, immersion in 10% caustic soda is suggested.
Easy-flo Flux Stainless Steel Grade	550–775	F-SH1	Powder	More active than Easy-flo Flux. Recommended for use on stainless steel with the lower melting-point brazing alloys.	
Easy-flo Flux Aluminium Bronze Grade	550–800	F-SH1	Paste	Similar for Easy-flo Flux Paste but modified for use on alloys containing up to 10% aluminium.	When finished components are heavily oxidized, cleaning and flux removal may be accomplished by the use of 10% sulphuric acid
Tenacity Flux No. 6	550–800	F-SH1	Powder/Paste	An opaque flux due to the addition of elemental boron. Recommended for tungsten carbide, refractory metals and stainless steel.*	
Tenacity Flux No. 14	550–750	F-SH1	Powder	An extremely fluid flux principally developed to prevent red staining on brass.	
Tenacity Flux No. 4A	600–850	F-SH1/2	Powder	A general-purpose flux with good resistance to overheating, used with higher melting temperature.	
Tenacity Flux No. 5	600–900	F-SH1/2	Powder	Recommended for stainless steel and heavy assemblies, where flux exhaustion is likely to occur due to prolonged heating	Residues are virtually insoluble in water.
Tenacity Flux No. 125	750–1200	F-SH2/3	Powder/Paste	A general-purpose high temperature flux for use with the bronze alloys.	Immersion in 10% caustic soda or mechanical removal is recommended.
Tenacity Flux No. 12	800–1300	F-SH3	Powder	A fluoride-free, high temperature flux for use with 'B' Bronze and 'G' Bronze.	
Silver-flo	550–775	F-SH1	Paste	A general purpose flux paste which combines exceptional activity with low fluxing temperature and melt viscosity.	
Mattiflux 100	550–800	F-SH1	Paste	Combines a relatively low melt viscosity with a good resistance to overheating and is particularly well suited to brazing mild steel assemblies.	

* This flux is unsuitable for use on stainless steel where crevice corrosion is likely to be a hazard in service.

Specialised silver brazing alloys

Description	Nominal composition	Melting range (°C)		BS 1845	Remarks
		Solidus	Liquidus		
Silver-flo 60	60% Ag:Cu:Zn	695	730	AG13	Principally used for brazing assemblies which will be exposed to sea water. Easy-flo No. 3 and Silver-flo 55 are also suitable for marine service.
Silver-flo 43	43% Ag:Cu:Zn	690	775	AG5	
Argo-braze 56	56% Ag:Cu:In:Ni	600	711	—	Specifically developed to prevent crevice corrosion, which may result in rapid failure of joints in stainless steel when exposed to water.
Argo-braze 35	35% Ag:Cu:Sn:Ni	685	887	—	An economical alloy suitable for fluxless brazing. Principally used on stainless steel and nickel silver.
Silver-copper eutectic	72% Ag:Cu	778	778	AG7 and AG7V	Ideal for fluxless brazing of copper, nickel and metallized ceramics. Available in two grades: Grade 1 (AG7V), a high purity material for brazing assemblies which will operate in vacuum. Grade 3 (AG7) for general engineering.
RTSN	60% Ag:Cu:Sn	602	718	—	Suitable for fluxless furnace brazing. Relatively fast heating rates necessary to avoid liquation.
15% Manganese-silver	85% Ag:Mn	951	960	AG19	A copper-free alloy for brazing assemblies which will be in contact with ammonia.

Flux coated rods

Alloy	Nominal composition	Melting range (°C)	BS 1845	Remarks
Cadmium bearing				
Easy-flo No. 2	42% Ag:Cu:Zn:Cd	608–617	AG2	A very fluid alloy, ideal for small components.
DIN Argo-flo	40% Ag:Cu:Zn:Cd	595–630	—	A general-purpose alloy with good flow characteristics.
Mattibraze 34	34% Ag:Cu:Zn:Cd	612–668	AG11	Fillet-forming alloys with limited flow characteristics.
Argo-swift	30% Ag:Cu:Zn:Cd	607–685	AG12	
Cadmium free				
Silver-flo 55	55% Ag:Cu:Zn:Sn	630–660	AG14	A free-flowing alloy generally suitable for all applications where a neat appearance is required.
Silver-flo 40	40% Ag:Cu:Zn:Sn	650–710	AG20	
Silver-flo 33	33% Ag:Cu:Zn	700–740	—	A range of cadmium-free alloys with fillet-forming properties.
Silver-flo 30	30% Ag:Cu:Zn	695–770	—	
Silver-flo 20	20% Ag:Cu:Zn:Si	776–815	—	An economical alloy suitable for brazing mild steel and copper.

Copper base brazing alloys

Description	Nominal composition	Melting range (°C)		BS 1845	Remarks
		Solidus	Liquidus		
'B' Bronze	97% Cu:Ni:B	1081	1101	CU7	Ideal substitute for pure copper in furnace brazing where joint gaps range from interference to 0.5 mm.
'C' Bronze	86% Cu:Mn:Ni	965	995	—	Suitable for furnace brazing. Requires a dewpoint of better than − 40°C, or a small addition of flux.
'D' Bronze	86% Cu:Mn:Co	980	1030	—	Recommended for brazing cemented carbide into rock drills and similar percussively loaded joints.
'F' Bronze	58% Cu:Zn:Mn:Co	890	930	—	
'G' Bronze	97% Cu:Ni:Si	1090	1100	—	The group offers a range of brazing characteristics to match different material and heat-treatment requirements.
Argentel	49% Cu:Zn:Ni:Si	913	930	CZ8	Low cost alloys ideal for use on tubular steel furniture and display racks. The high strength of Argentel makes it particularly suitable for butt joints while Argentel B offers improved flow characteristics and a lower working temperature.
Argentel B	57% Cu: Zn: Ni: Mn: Si	890	910	—	

Silver-bearing soft solders

Description	Nominal composition	Melting range (°C)		Remarks
		Solidus	Liquidus	
Plumbsol	2.5% Ag:Sn	221	225	Lead-free alloys ideal for use in plumbing and the fabrication of assemblies where toxicity is a problem.
P35	3.5% Ag:Sn	221	221	Good colour match on stainless steel.
P5	5% Ag:Sn	221	235	P35 and P5 are stronger than tin-lead alloys at elevated temperatures.
Ceramic No. 1	9% Ag:Sn:Pb	183	250	For soldering of silver-metallized components in the electronics industry.
Comsol	1.5% Ag:Sn:Pb	296	296	Good creep resistance at elevated temperatures. Suitable for soldering armature windings and radiators.
A25	2.5% Ag:Pb	304	304	For use in 'hard chlorinated waters where tin-bearing alloys
A5	5% Ag:Pb	304	370	suffer corrosion.
LM10A	10% Ag:Sn:Cu	214	275	A free-flowing alloy with above average tensile strength and creep resistance.
LM15	5% Ag:Cd:Zn	280	320	The strongest alloy in the soft solder range. Used where temperature limitations do not permit silver brazing.
LM5	5% Ag:Cd	338	390	Can be considered for applications where good strength at moderate temperatures is necessary.

Soft solder fluxes

Description	Flux residue removal	Working range (°C)	Remarks
Soft Solder Flux No. 1	Corrosive – can be removed with cold water	150–400	A general-purpose acid flux suitable for copper, brass, mild steel and stainless steel.
Soft Solder Flux No. 2	Non-corrosive – can be removed with cold water	150–400	Recommended where flux residues cannot be removed. Suitable for copper, brass and most plated surfaces.

Refraction and reflection

If a ray of light is incident obliquely at a point O on a glass slab and the normal N is drawn at the point O, the light ray is refracted or bent in towards the normal. If i is the angle of incidence and r the angle of refraction to the normal it can be seen that if a ray passes from a rare (air) to a denser medium (glass or water) it is refracted towards the normal (Fig. A11.1*a*). We then have $\sin i/\sin r = \eta$ (refractive index) The value of η is constant for a given pair of media (Snell's law).

Upon emerging from the denser to the rarer medium the ray is refracted away from the normal by the same amount but is displaced by an amount which depends upon the distance travelled through the denser medium (Fig. A11.1*b*).

A stick partly immersed obliquely in water appears to be bent due to the refraction of the light from the immersed end of the stick.

Fig. A11.1 (*a*)

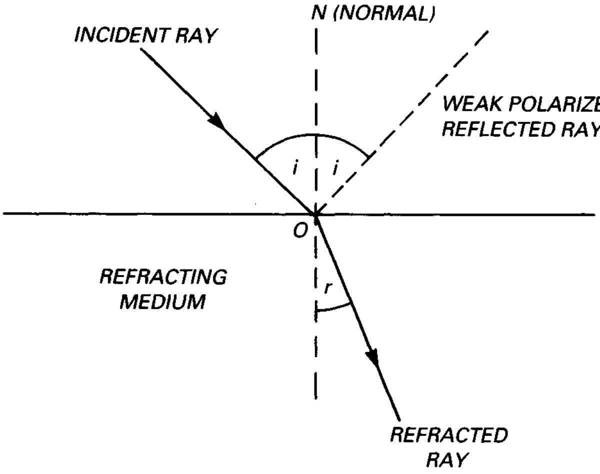

Fig. A11.1 (*b*)

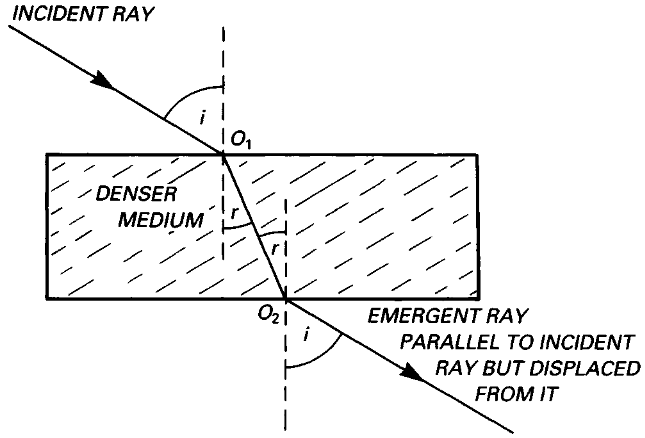


Polarization

We have seen that a ray of light is an electromagnetic radiation having two component fields, one electric and the other magnetic, vibrating or oscillating at random, at right angles to each other and at right angles to the direction of travel of the ray.

If the ray is passed through certain substances that allow the electric forces in one plane only to pass through the substance, the emergent light is said to be plane polarized with the electric forces vibrating in the plane of polarization.

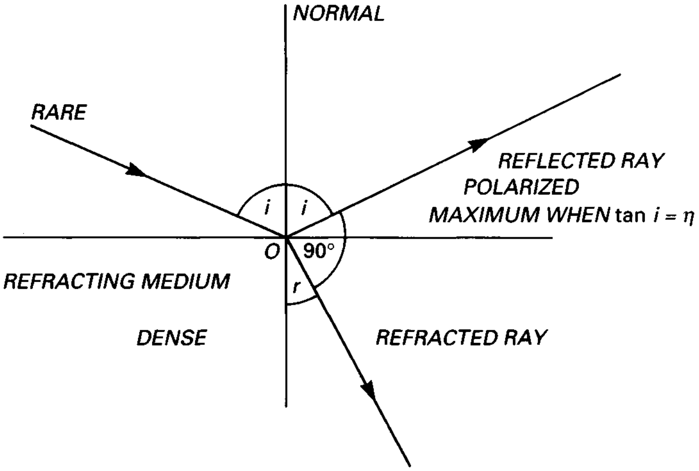
Polaroid is the trade name given to a substance of paper-like consistency impregnated with chemicals, which gives an emergent polarized ray when a light ray is passed through it. It is cheaper than the Nicol prism (calcite or Iceland spar) and is supplied in sheets of various sizes. The emergent polarized ray has the electric forces vibrating in the plane of polarization of the sheet.

If a second sheet is placed at a little distance from, and parallel to, the first sheet, with its plane of polarization in the same direction, the ray of polarized light emergent from the second sheet suffers virtually no loss. Now rotate the second sheet about the axis of the ray and it will be seen that the polarized ray emergent from the second sheet becomes darker and darker until darkness occurs when the planes of polarization of the two sheets are at right angles to each other. There is now no emergent ray, the polarized ray from the first sheet being completely quenched by the second sheet. The first sheet is termed the polarizer and the second sheet the analyser.

If a solution of a salt is placed in a tube between the sheets, the analyser has now to be rotated through an angle greater than a right angle to the first sheet to obtain darkness. The solution has rotated the plane of polarization of the ray by an amount depending upon its strength, so that by comparing the increased rotation per unit length of various solutions their strengths may be compared.

The eye cannot differentiate between unpolarized and polarized light. When an unpolarized ray of light is incident at an oblique angle on a surface such as glass or water, part is reflected at the surface and the remainder is refracted into the medium (Fig. A11.2). The reflected component is part plane polarized and this is a maximum when the angle between the reflected polarized ray and the refracted ray is a right angle. This leads to Brewster's law, which states that the angle of polarization at the surface of a medium is the angle whose tangent is equal to the refractive index of the medium.

Fig. A11.2



Appendix 12

*Notes on the welding of Duplex and Super Duplex stainless steels**

Duplex and Super Duplex stainless steels are particularly useful in the petrochemical industry because of their pitting and corrosion resistance. Duplex stainless steels are so called because they have two phases in their microstructure, ferrite and austenite, so they are ferritic–austenitic steels. One of the most common of the Duplex steels has 22 % Cr, 5 % Ni, 3 % Mo and 1 % N_2, remainder ferrite. The ferrite gives the high tensile strength and the austenite gives the toughness. The latest of these steels is called Super Duplex stainless steel and has a greater resistance to corrosion and a high pitting resistance. A typical example of a Super Duplex steel has 25 % Cr, 7 % Ni, 4 % Mo and 0.15 % N_2, remainder ferrite. Duplex steels are not sensitive to corrosion cracking but must not be worked above 300 °C, as above this embrittlement occurs. The ferritic–austenitic balance is important as a high ferrite content will cause brittleness and a low one will cause a lowering of resistance to stress corrosion. Contents of 30–70 FN (ferrite number) are normal. The balance between ferrite and austenite depends upon the heat treatment and the composition of the filler metal, the heat input when welding and the interpass temperature. A filler wire should always be used and the result will be a strong and sound weld and HAZ. Welding without any filler rod and excessive dilution of the weld and parent metal produce an excess of ferrite causing the weld metal to be brittle. The interpass temperature must *not* exceed 150 °C (Super Duplex steels are particularly sensitive to high heat input and the temperature of the interpass runs).

To summarize: high heat input and high interpass temperature give a low cooling rate resulting in brittle phases forming during cooling, whereas low heat input and low interpass temperature during welding give a high cooling rate, resulting in more ferrite and lower toughness resistance. The gases used for the various processes are: argon or argon–helium mixtures for TIG; argon–oxygen, argon–carbon dioxide or argon–helium–oxygen mixtures for MIG; and argon–carbon dioxide or pure carbon dioxide for flux cored arc welding (FCAW).

---

* Details of the article and table of consumables by permission of ESAB (UK) Ltd.

When welding Duplex steels it is essential to use root gas shielding and this should be argon, or argon with a small amount of hydrogen or nitrogen, and the mixture should be checked to ensure its efficiency. The addition of nitrogen to the backing or shielding gas improves the corrosion resistance while chromium, molybdenum and nitrogen determine the resistance to pitting. The pitting resistance equivalent $(\text{PRE}) = \%\text{Cr} + 3.3\,\%\ \text{Mo} + 16\,\%\ \text{N}_2$. A PRE of 40 is often used as a definition of a Super Duplex stainless steel. For the estimation of the critical pitting temperature (CPT) ferric chloride is used with a minimum CPT of 40 °C for Super Duplex, and this may be as high as 60 °C for weld metal that has to stand immersion in sea water (Super Duplex OK 68.53 is a good example). Welds made in Super Duplex steels containing small percentages of copper and tungsten often give CPTs of 45–50 °C in this test. This is a good test for sea water corrosion and pitting. The amount of ferrite in the final weld can be estimated by constructing a constitutional diagram using the chromium equivalent along the horizontal axis and the nickel equivalent along the vertical axis. The varying dilutions are indicated by lines on the diagram representing all the compositions of the weld metal that can occur. The chosen dilution is made and other lines drawn to indicate the possible ferrite content of the weld (see, for example, p. 69).

When welding Duplex steels the parts should be thoroughly cleaned and brushed with a hand-held brush with stainless steel wires. Use dry electrodes and if necessary warm them before use. Do *not* preheat. The heat input of the run will vary with the plate thickness but must not be too high or too low. Do not strike the arc anywhere outside the joint as this may lead to the initiation of corrosion and cracking. Avoid excessive weaving as this may over-heat the weld. See that the backing gas of pure argon with small amounts of nitrogen or hydrogen is functioning. After welding, clean off all slag and any other foreign matter with a hand-held stainless steel brush. Do not use rotary brushes as they make almost invisible scratches which can lead to corrosion. No post-heating is required, but the part may be solution-treated (see Vol. 1, p. 130, for description of solution treatment). Do not attempt any stress relief. In other words, the part or welded structure should *not* have any heat treatment.

The arc energy can be calculated in the following way:

$$\text{arc energy (kJ/mm)} = \frac{\text{arc voltage} \times \text{welding current}}{\text{welding speed (mm/s)} \times 1000} \quad \text{(see p. 80).}$$

Consumables for welding Duplex and Super Duplex stainless steel

Composition of base metal (%)	FN	MMA	MIG	TIG	FCAW	SAW
23 Cr, 4 Ni, 0.1 N	30–45	67 50 Rutile 67 53 Rutile	Autrod 16 86	Tigrod 16 86	Tubrod 14 37	Flux 10 93 Autrod 16 86

25 Cr, 6.5 Ni, 3 Mo, 0.18 N	30–50	68 53 Basic 68 55 Basic		Tigrod 16 88		Flux 10 94 Autrod 16 88
25 Cr, 6 Ni, 3 Mo, 2 Cu, 0.20 N	30–50	68 53 Basic 68 55 Basic		Tigrod 16 88		Flux 10 94 Autrod 16 88
25 Cr, 6 Ni, 3 Mo, 0.7 Cu, 0.7 W, 0.25 N	30–50	68 53 Basic 68 55 Basic		Tigrod 16 88		Flux 10 94 Autrod 16 88
25 Cr, 6 Ni, 3 Mo, 0.7 Cu, 0.7 W, 0.25 N	30–50	68 53 Basic		Tigrod 16 88		Flux 10 94 Autrod 16 88

Note: All electrodes, wires and fluxes are prefixed with the letters OK (e.g. OK 67 50); FN is the ferrite number.

As an example, suppose that for Duplex steels the arc energy is within the range 0.5–2.5 kJ/mm, and for Super Duplex stainless steels the arc energy is within the range 0.2–1.5 kJ/mm. Suppose also that a Super Duplex steel has an arc voltage drop of 20, a welding current of 80 A and a welding speed of 1.5 mm/s. Then from the above formula:

$$\text{arc energy} = \frac{20 \times 80}{1.5 \times 1000} \approx 1.1 \text{ kJ/mm}.$$

This setting would be suitable for both steels as an arc energy of 1.1 kJ/mm falls within the above limits for both steels.

Suppose, now, that for a Duplex steel the arc voltage drop is 20, with a welding current 100 A and a welding speed of 1.0 mm/s, then

$$\text{arc energy} = \frac{20 \times 100}{1.0 \times 1000} \approx 2.0\ \text{kJ/mm}.$$

This setting of current and weld speed is suitable for Duplex steels only, as the arc energy falls outside the figure given for Super Duplex stainless steels.

Overalloying

Note that in all consumables used for welding Duplex and Super Duplex stainless steels there is more nickel than normal. This 'overalloying' is to help the formation of austenite so that there is not too much ferrite in the final weld metal. The use of a filler material and only a small weave, in addition to the excess nickel, prevents excessive dilution, which would increase the ferrite content and hence the brittleness of the weld.

Appendix 13

Welding fumes: health and safety

The electric arc, used in MMA, MIG–MAG, TIG, and other welding processes, causes visible and invisible fumes to be given off by the melting flux when the arc is burning. These fumes can be harmful if inhaled through the nose and mouth of the welder. The content of the fumes may be either asphyxiating or toxic.

Asphyxiating fumes

Asphyxiating fumes are largely due to the shielding gases used around the arc. They are invisible and produce their effect by displacement of the surrounding air and thus, of its oxygen. (The air which we breathe consists mainly of nitrogen and oxygen, roughly in the ratio of four parts nitrogen to one part oxygen.) Asphyxiation begins when the oxygen content of the air falls below about 18 %.

The gases usually used in welding are argon, carbon dioxide, helium and their mixtures. Argon and carbon dioxide are heavier than air (the mixtures are known under trade names). A mixture is selected to give the best welding conditions for a particular process. A simple mixture is the rutile coating for mild steel electrodes in the MMA welding of mild steel. The rutile gives a smooth arc, which is easily managed, but it gives off some hydrogen, which is absorbed by the molten metal and leads to hydrogen cracking under certain conditions of stress. To prevent this the covering is of calcium carbonate ($CaCO_3$), mixed with a little rutile in order to give a smooth and easily managed arc. This mixture now gives off only a little hydrogen (a low hydrogen electrode), which can be used where higher stresses are encountered. The proportion of asphyxiating gas present is generally given in parts per million (p.p.m.) (this can be converted into milligrams per cubic metre of the atmosphere (mg/m^3)).

The mixtures with argon are, like the argon, generally heavier than air

Asphyxiating gases

Asphyxiant	Notes
Argon (Ar)	Non-toxic. Used as a shielding gas, alone or mixed with other gases. Heavier than air and can accumulate at the base of any closed vessel being welded and can form layers at the bottom of the welding operation in a badly ventilated welding shop. Essential to have extraction and circulation of the atmosphere around the welding point.
Helium (He)	Non-toxic. Used generally mixed with other gases (e.g. 50% helium 50% argon). Helium is not produced in this country but is imported from the United States and is therefore much more expensive than argon.
Oxygen (O_2)	Non-toxic but it promotes rapid oxidation especially in the pure state. Atmosphere roughly 4 parts nitrogen to 1 part oxygen (the proportions required by the human body to enable it to function). Used in small quantities (1% to 2%) mixed with argon for stainless steel welding.
Nitrogen (N_2)	Although nitrogen is used for displacing the atmosphere in tanks and pipelines it is not a neutral gas like argon because it forms compounds with other substances. Two of these are produced in welding, namely nitric oxide (NO) and nitrogen dioxide (NO_2), both of which are toxic (q.v.) as nitrogen itself is an asphyxiant. Nitrogen is produced in large quantities as a by-product in oxygen-making plants.

and invisible. They tend to sink to the floor, making an asphyxiating layer which becomes deeper as welding continues. Evaporation and vaporization of the metal from the molten pool rise with the other fumes but are invisible.

*Toxic fumes**

Toxic fumes are made up of very many tiny particles of the flux covering of the electrode, the central core of the flux (if used), and the vapours from the metallic evaporation of the molten metal of the arc; the fumes rise to give the familiar welding fumes. Note that the size of the particles is extremely small. The student should read publications EH40, EH54 and EH55†, together with the COSHH regulations to get a complete

---

* *Note.* Spatter, which appears as sparks (which are globules of molten metal ejected from the arc), is not classified as fumes.

† All booklets mentioned are published by HMSO and can be obtained from any branch office, or by post from HMSO Books, PO Box 276, London SW8 5DT. They are written by the Health and Safety Executive (HSE) and are available in most libraries, colleges and universities. The full titles are:

HSE Guidance Notes EH40: Occupational Exposure Limits
Guidance Notes EH54: Assessment of Exposure to Fume from Welding and Allied Processes
Guidance Notes EH55: Control, Exposure, Fumes, Welding, Brazing and Similar Processes

picture of this important subject. Booklet EH40 xx (xx indicates the year of printing) gives, in detail, an explanation of the exposure limits. Because the limits are updated each year the values have been omitted from the following table. The student is advised to fill them in using pencil and to keep them up to date. Note that the total fumes inhaled should not exceed 5 mg/m^3.

The following terms are used in EH40:

OES	Occupational exposure standard (given in mg/m^3 or p.p.m. over a given time period).
MEL	Maximum exposure limit (given in mg/m^3 or p.p.m.).
TWA	Time-weighted average. Allowance is made for the periods when the arc is not burning.
ID	Inhalable dust (total dust inhaled).
RD	Respirable dust (quantity of dust that enters the respiratory tract and lungs).
STEL	Short-term exposure limit.

The removal of asphyxiating and toxic welding fumes

If welding is performed outside, there is a constantly changing atmosphere around the welding area, so that the extraction of fumes may not be necessary, but careful assessment should be made to confirm this. If a wind is blowing, however, screens should be set up to prevent the gas shield around the arc being disturbed. If necessary the electrode wire should be flux cored to lessen the effect.

The welding shop should be as large, airy and high as possible. Sometimes there may be long narrow ducts at ground level through which clean air is blown, and similar ducts at ceiling height to enable the polluted air to be exhausted. Even with heated clean air being blown in through the bottom ducts the shop will be very cold in winter time and the heating of the air will add to the cost of welding.

A popular method of eliminating fumes, in use today, consists of a suction unit fitted with a filter, from the suction side of which a large-diameter, fixed, rigid tube is fitted. This tube passes down the shop (well above head height) and over every welding position or bench. Flexible tubes of a similar large diameter are fitted, which reach down to the welding position or bench. At the lower end of the flexible tube a collecting head is fitted (see Figs. A13.1 and A13.2). The tube is sufficiently rigid to remain in any position in which it is placed and the collecting head may be fitted with a magnet to help positioning of the collector. For long

Table of substances in fluxes which produce toxic fumes

Substance	Notes	OES mg/m^3	TWA 8 h STEL	MEL mg/m^3	TWA 8 h STEL
Aluminium and its alloys, aluminium oxides Al_2O_3, $Al(OH)_3$, Al(OOH))	Fumes are produced when welding aluminium and its alloys. Inhaling the fumes over long periods may affect the respiratory tract.				
Cadmium and its compounds, cadmium oxide fume	These are highly toxic and are generally formed when welding articles that have been cadmium plated. Clean off in the areas to be welded.				
Calcium, calcium oxide, calcium hydroxide, calcium carbonate, calcium silicate	Though non-toxic, fumes may irritate the respiratory tract when in large concentrations.				
Carbon dioxide	Present mixed with many types of shielding gases. It is mildly toxic and, being slightly heavier than air, sinks to the base of closed containers when welding. With the other gases it acts as an asphyxiant.				
Carbon monoxide	Very toxic. Small amounts are formed when CO_2 is present as a shielding gas.				
Chromium and its compounds, chromium II, chromium III (trivalent), chromium VI (hexavalent)	Fumes are produced when welding stainless steel and other alloys with a high chromium content. These are all toxic and those of chromium III and VI may be carcinogenic.				
Copper and its compounds, fumes, dust and mists	Toxic fumes are produced when welding copper. Most welding wires for welding steel by the MIG process are copper coated to prevent rusting, but produce very few copper fumes.				
Iron and its compounds, iron oxide fumes Fe_2O_3, iron salts	Only slightly toxic and found when welding steels. Welding may cause deposits upon the lungs.				

Table continued

Substance	Notes	OES mg/m^3	TWA 8 h STEL	MEL mg/m^3	TWA 8 h STEL
Lead and its compounds, lead in the atmosphere (lead in the air is taken as standard)	Very toxic. Large amounts of fumes are produced when welding heavily lead-painted articles (clean off paint where required). Fumes are given off when lead is welded. These are very toxic.				
Magnesium, magnesium oxide (MgO)	Formed when welding high magnesium content aluminium alloys, which work-harden.				
Manganese and its compounds	Fumes are toxic. Manganese is used as an alloying element in steel making, 12–14% manganese steel work-hardens and is work resistant. Fumes affect the nervous system and respiratory tract.				
Barium (soluble) and its compounds	Highly toxic and found in some flux cored wires.				
Nickel and its compounds, soluble compounds	Present as an alloy in many steels and in stainless steel as a major alloying element. Fumes are very toxic. Affects the respiratory tract and produces metal fume fever. May be carcinogenic.				
Silicon, silica (SiO_2)	Non-toxic. Contained in some fluxes in core or covering. Little effect on welding fumes as only small amounts are formed.				
Zinc and its compounds, zinc oxide (ZnO), zinc chloride (ZnCl)	Toxic. Fumes of zinc oxide are given off copiously when welding galvanized articles, the coating of which is zinc. Grind off the coating from areas to be welded.

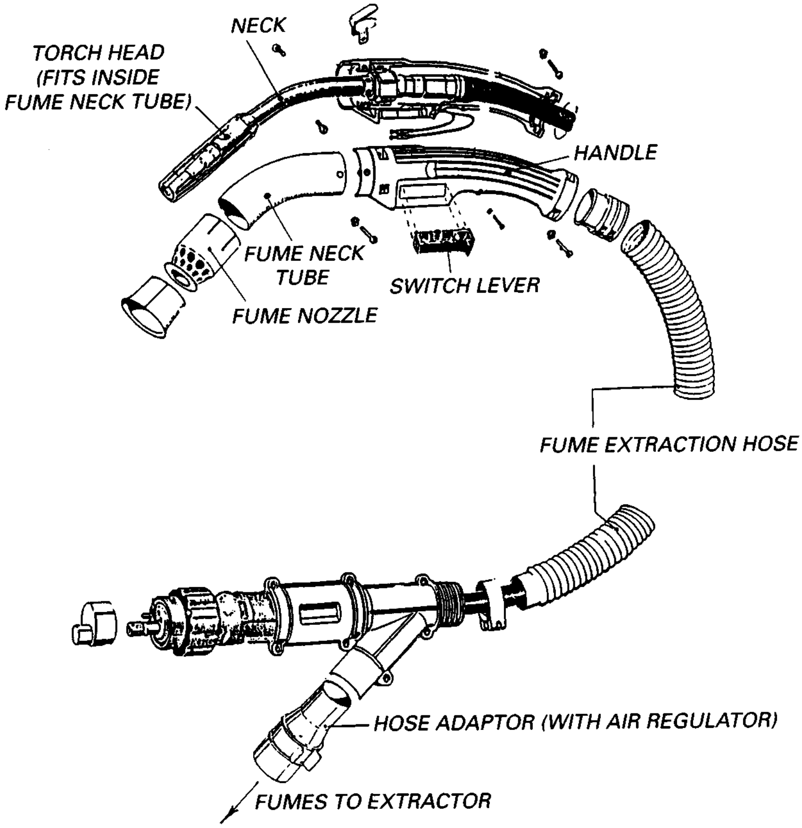
extensions from the overhead tube, the flexible tube may be fitted with several jointed or articulated arms passing inside the tube. These arms are a great help in positioning the collector in cases on the shop floor when the cantilever effect is maximum. The collecting head may be fitted with a shutter, hand-operated from outside the head, so that an operator can switch off the suction without affecting other welders on the same circuit. In addition, there may be a protected electric light to assist the operator in positioning the work. For larger articles and fabrications a portable unit can be used.

The filter, starting unit and electric motor are all mounted on wheels and can easily be moved around. A large-bore flexible tube is fitted to the suction side of the unit and the collector is positioned by the welder, the collector being above weld level and as close as possible to the weld without impairing the work of the welder. The extracted air is filtered to remove the fumes, and the air is then returned to the atmosphere.

For this kind of work the suction rail method is useful. This consists of a fixed large-diameter tube fitted with rails. A collector on the rails and running on wheels is pulled to cover any desired point in the fabrication, and the tube on the collector delivers the air and fumes directly into the suction tube. The clean air exhausts to the atmosphere no matter where the trolley is placed.

In some cases, when MIG welding, the gun may incorporate fume-collecting ducts. In the body of such a gun, towards the lower end, are some holes or ducts (see Fig. A.13.3). The fumes are sucked in through the holes,

Fig. A13.3. MIG gun with built-in fume collector (Murex).



NECK

FUMES TO EXTRACTOR

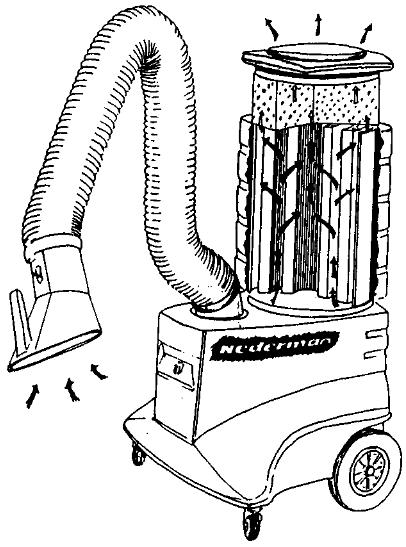
up the bore of the gun and are quite separate from the shielding gas and water-cooling (if any) supply. Higher up the gun is an angled unit attached to the suction tube of the fume-cleaning unit. The fumes are collected as they are made, and collection does not interfere with the shielding gas supply. The fumes pass up the gun and are filtered and exhausted as described earlier. Note that these guns are available only for MIG welding.

Electrostatic precipitation can be utilized where it is inconvenient to install a fixed collector. Upon entering the precipitator, fume particles are charged electrostatically and then pass through an insulated sleeved tube to plates of opposite polarity to that of the particles. They are deposited on the plates, which are part of the filtering elements, and the air issuing from the unit is fumeless and is returned to the atmosphere. Fig. A13.4 shows a Sectional view of a filter.

Efficient extraction of fumes is essential to the long-term health of the welder, as it may be many years until the effects of fumes inhaled over a long period are apparent. Almost all the toxic substances in the table above have a long-term effect on the respiratory tract and lungs, and in time seriously affect the health of the operator. Therefore, take all precautions possible:

> Never weld with head and helmet directly in the path of rising fumes.

Fig. A13.4. Mobile unit with filter. Arrows show passage of fumes through the replaceable paper filter. In the electronic model an additional motor cleans the filter elements and indicates when the main container needs emptying.



Never use a flat shield.
Use a head shield that protects the face, head-sides and neck.
Use a filter glass of the deepest shade compatible with the weld being performed.
Wear gloves to protect hands and wrists from the harmful effects of UV rays.
Never weld with the sleeves rolled up.
Protect the body skin by covering it.

However carefully employers safeguard the health of their welding operators in the welding shop or fabricating area within the COSHH regulations and the HSE recommendations, it is finally up to the welder to safeguard his or her health, by following these regulations regarding toxic fumes and asphyxiating gases. Figs. A13.1–A13.4 should make some of the apparatus for toxic fume removal quite clear.

Free information booklets on the hazards to health from welding fumes are provided by the makers of the electrodes and gas suppliers, for example:

Appendix 14*

Lasers and laser welding

Notes on the laser

The cost of the CO_2 lasers has mitigated against their general acceptance by industry, except for heavier work. They can perform welding, cutting, drilling, spot welding and marking operations quickly and efficiently, with very little distortion, due to the narrow HAZ, but it is still only the larger firms that use them where there is much repetition work. We will discuss the following types of laser here: solid state, such as the Nd–YAG, and gas, such as the CO_2 axial flow and the CO_2 transverse or cross flow.

The Nd–YAG laser

The Nd–YAG laser is of neodymium and yttrium–aluminium garnet (the last word indicating that its crystals are cubic). This laser is relatively light and portable, and its use is greatly increased by the fact that the laser beam can be conducted along a fibre-optic cable to a gun head, and can thus reach awkward places. It is used for marking hardened parts and no matter how thin, these are clearly marked using a low-power laser (Fig. A14.1). The drilling of thin sheet and stainless steel is performed with a very small focussed beam; the width of the beam determines the hole diameter.

The power output of a laser depends upon its length and its capacity to keep cool. The laser is contained within a unit called a resonator and the whole is water-cooled. The Nd–YAG laser passes the electric field, the beam and photons with ease and is used in the power range 50 W to 3 kW, the low input giving a very narrow HAZ. Above this power range the heat produced renders its operation greatly restricted. It is fast in the welding

---

operation and is particularly useful in welding thin sections of steel and stainless steel of about 2 mm or less. Fit up is extremely important since any gaps between the sections being welded allow the beam to traverse in this area without welding. For this reason butt welds in shafts and those in tubes of stainless steel or steel must be perfectly butted. The spot welding of thin sheets can also be carried out without distortion. No filler rod is used and the weld is performed as a keyhole weld (described on p. 194 and illustrated in Fig. A14.2). Any gases used are described on pp. 36 and 106 of Vol. 1, and focussing the spot on p. 241.

The CO_2 laser

For welding thicker materials, the CO_2 laser is usually used, and is available in sizes 0.4–30 kW. Many lasers in the USA have been produced with very much greater outputs than this but information on them is difficult to obtain. These high-powered lasers have uses other than for welding and cutting. The solid state Nd–YAG laser is used for materials (steel) down to 0.2 mm and less. Others of this type are being developed, but the YAG rod gets very hot at these higher powers and so the CO_2 laser is used. There are two types: axial flow, in which the gas flow

is in line with the optical axis, and cross or transverse flow, in which the gas flow is at right angles to the optical axis.

The axial laser consists of a resonator tube or chamber containing CO_2 and traces of He (helium) and N_2 (nitrogen) to give easy starting and good beam characteristics at a pressure of about 60 millibars. Air is pumped out of this resonator before the CO_2, He and N_2 are introduced. The gases are circulated by a fan or compressor and this keeps the pressure in the tube constant. During operation there is some degrading of these gases and this is slowly bled off and replaced by fresh CO_2, He and N_2, as required, keeping the pressure constant. Heat exchangers keep the unit cool. The electrical stimulation may be a.c. or d.c. and the power of the unit (electrical) is many times that of the laser beam, whose wavelength is approximately 1.06 μm. A simplified version of the axial flow laser is shown in Fig. A14.3, and the cross flow laser in Fig. A14.4.

The cross or transverse flow laser has the gases as before but the electrical stimulation is now at right angles to the optical axis and this type is usually of higher output than the axial flow type (Fig. A14.5).

In both cases the resonator tube usually consists of smaller tubes (lengthwise) fitted with reflective mirrors set at an angle of 45° to the axis

LASER LIGHT GENERATION ZONE
FULLY REFLECTING MIRROR
FOCUSSING MIRRORS: GLASS FOR LOW POWER COPPER FOR HIGH POWER
BEAM OUTPUT WINDOW
TO MAKE LASER LONGER AND THUS INCREASE ITS POWER THE BEAM IS FOLDED BACK AND FORTH AS SHOWN

of the beam (Fig. A14.6). These mirrors are generally of polished copper to stand the extra strength of the beam. The beam energy is evenly distributed over the width of the emergent beam in the case of the axial flow laser, while in the cross flow laser any parts of the beam that would miss the outgoing mirror are collected by a scraper at 45° to the emergent beam and the resultant beam is strengthened. The advantage of the folding-beam laser is that the power is increased without increasing the length of the unit.

Fig. A14.7(*a*), (*b*) shows sections through a laser weld. The parts to be welded have their ends machined so that there is an excellent fit up between them. If there is any poor fit up between the parts the beam passes this point and does not weld it. Note that the HAZ is extremely narrow, being widest where the weld commences. Because of this narrow zone there is little heat input to the parts and hence very little distortion. Sheet and plate are welded in the same manner or by spot welding in both steel and stainless steel. The method of welding is called 'keyhole' welding (Fig. A14.2, see also p. 194). No filler material is required. Since the width of the weld bead varies considerably for different size lasers it can be seen that the focussing of the beam to a small spot, say 0.15 to 2.2 mm diameter, exactly where the weld is to commence is essential. Focussing is done by an optical arrangement in the path of the emergent beam.

The laser is extremely useful in cutting both steel and stainless steel down to 0.5 mm. It is often preferable to use nitrogen as a shielding gas rather than add oxygen, since the edge of the cut is not oxidized in any way and, of course, there is little distortion.

The depth of penetration is an important feature of the laser beam. It has been found, in use, that a spot which was focussed correctly when work commenced may alter due to slight irregularities in the plates. For this reason some units are fitted with a self-adjusting mechanism (like a zoom lens) and this keeps the spot always correctly in focus and can save much time.

Fig. 14.7. (*a*) Weld in stainless steel pipe showing narrow HAZ.

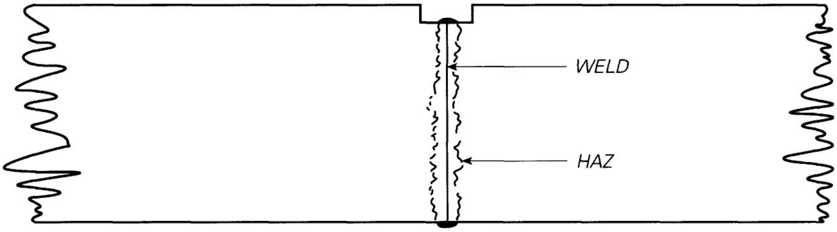

Fig. 14.7. (*b*) Section through a weld in stainless steel showing the narrow HAZ.

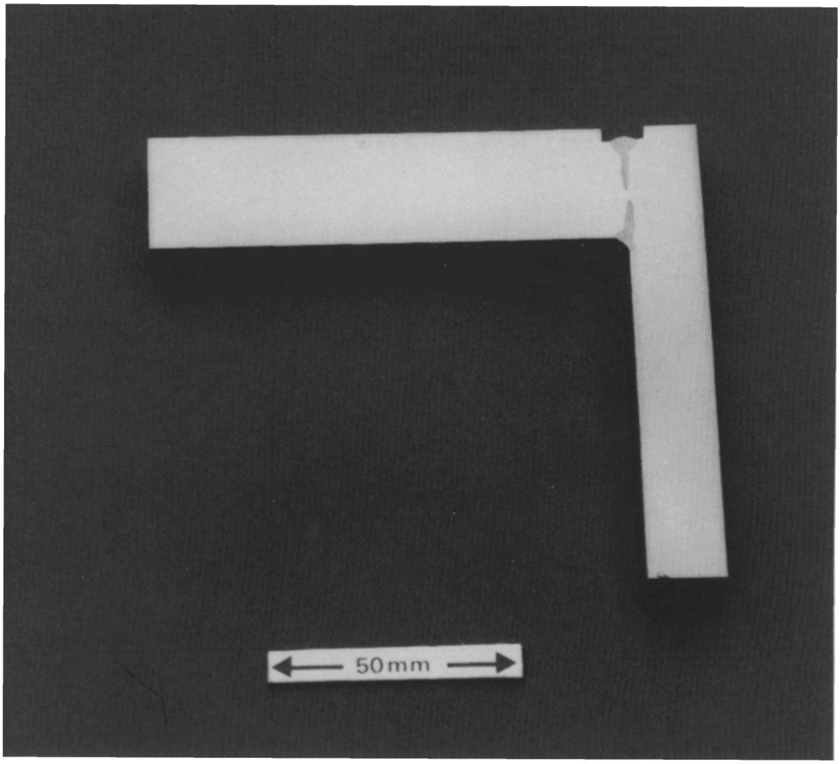


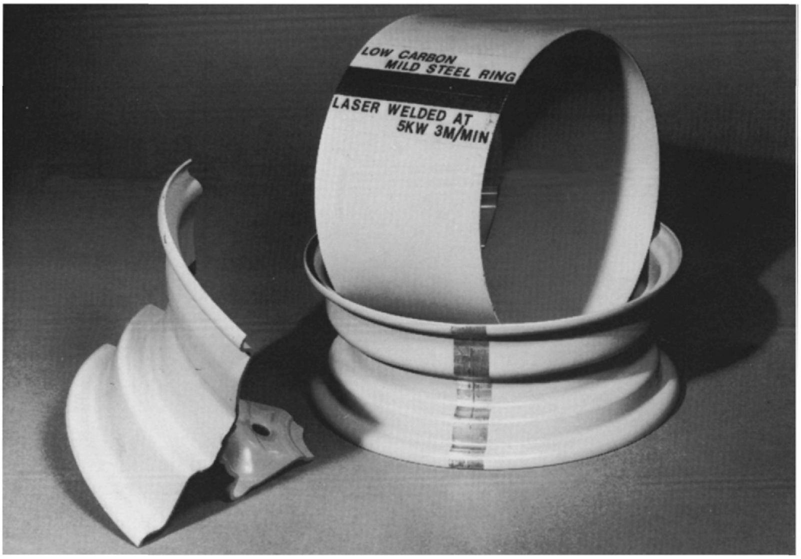
Laser welding of other metals

The laser welding of steel to steel (and stainless steel to stainless steel) can be performed quite easily since in both cases the parts to be welded have the same melting temperatures. Similarly stainless steel to ordinary steel welding is very satisfactory. When welding dissimilar metals together the melting temperatures and the ability of the metals to form a solid solution at the point of welding are very important (for example, steel to aluminium forms no solid solution). The table gives a list of dissimilar metals welded together, with notes on the weld.

Laser welding of steel, stainless steel, titanium, other alloys and cast iron

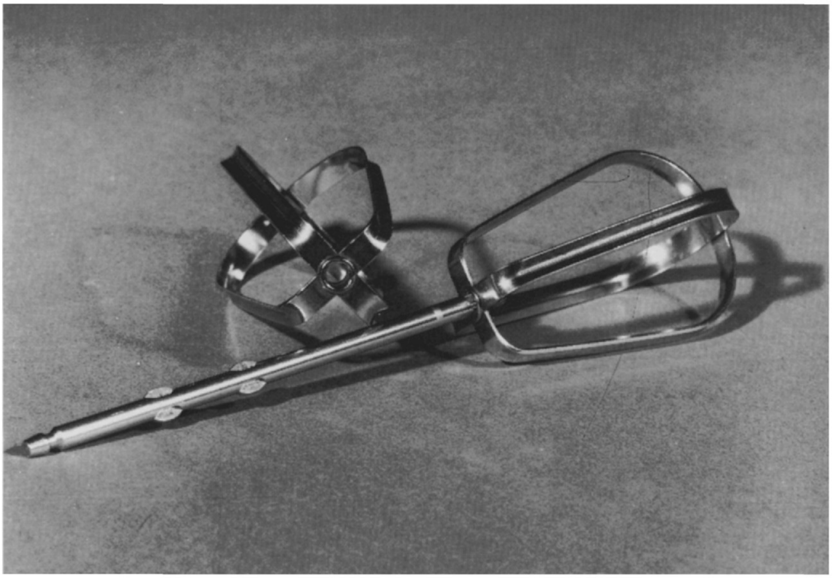
Material	Notes
Aluminium and its alloys	Not particularly satisfactory
Nickel and high nickel alloys such as MONEL®, INCONEL®, NIMONIC®, KOVAR®, HASTELOY®	Some of these weld well. Consult manufacturers
Cast iron	Any cast iron containing nickel can be welded if a nickel filler rod is used
Steel	Weldable. If high carbon content, care is required, special precautions must be taken
Low-carbon and high-strength low-alloy steels	These are very weldable if the sulphur and phosphorus content is low
Alloy steel	Weldable. Care must be taken to ensure that there is no hardening due to a fast welding rate
Stainless steels	
Austenitic	Most grades of steel give good welds except the free cutting steels with a high percentage of sulphur
Martensitic	Owing to hardening, steels with a high carbon and chromium content are satisfactorily welded. Otherwise welding is very difficult
Ferritic	Steels having low carbon and chromium (below 0.4%) give good welding properties. After welding, grain growth will affect the toughness
Titanium and its alloys	Good welds are obtainable with fine grain if the material is clean before welding. Note that high quality of shielding gas is required over the weld pool

Fig. 14.8. M/S plate. The sides of the rim are ring-pressed to shape, and laser welded outside onto the M/S ring.



LOW CARBON
MILD STEEL RING
LASER WELDED AT
5KW 3M/MIN

Fig. 14.8. Laser-welded food mixer.



Because the beam from an Nd–YAG laser can be transmitted down a 1 mm optic fibre cable it can be used to cut holes of this size in thin steel sheet such as used in car bodies. A 25 W Nd–YAG laser can cut steel down to 1 mm thickness.

Nitrogen or argon is used for the welding of motor vehicle gears in an inert atmosphere. Glove boxes are designed so that the welds can be carried out in an inert atmosphere. This is very useful when welding any reactive metals such as titanium.

An Nd–YAG laser of 35 W capacity can be used for very small work such as engraving.

Figs. A14.8 and A14.9 show further examples of laser welding.

Advantages and disadvantages of laser welding and cutting

Advantages

(1) Very narrow HAZ, so little or no distortion (e.g. finished gears welded together).
(2) Depth of penetration limited only by power of laser.
(3) Welding speeds are increased.
(4) Useful if the point of access is poor.
(5) Useful for welding, cutting, heat treatment and marking.
(6) Very thin sections can be welded or cut with little distortion.
(7) Surface treatment is easily carried out.

Disadvantages

(1) Surface to be welded must fit up accurately.
(2) Joint alignment and focussing of beam must be accurately set.
(3) Cost of equipment and its layout is very high.
(4) Beam energy must be accurately controlled.
(5) Equipment is not easily transportable.
(6) The beam is highly dangerous and must never be allowed to fall on human skin.

Sizes of laser are roughly:

Welding – Pulsed Nd–YAG laser welding of sizes 3–4 kW, distortion-free, deep weld penetration.

Cutting – $CO_2 + He + N_2$, 0.75–25 kW and continuous wave. Cooled lasers of 2 kW and upwards output.

Marking – Lasers 25–150 W in metals, ceramics and plastics.

Manual metal arc

1 State *four* precautions which should be taken to protect the eyes and skin of the welder and other workers exposed to radiation from arc welding operations.

2 Sketch and label *three* defects that may occur in a double-vee butt welded joint which would affect fatigue strength.

3 Give *three* reasons why hydrogen-controlled electrodes are often used in preference to general purpose electrodes for welding low-alloy steels.

4 (*a*) Explain why the degree of penetration is greater using a cellulose-covered electrode compared to a rutile-covered electrode using the same heat input.
  (*b*) An electrode used for manual metal-arc welding has over 100 per cent metal recovery. State
    (1) the addition which must have been made to the covering,
    (2) *two* advantages of using this type of electrode.

5 The figure shows two views of a fractured grey cast-iron bracket which is to be repaired by the manual metal-arc process.

(*a*) Make a pictorial sketch of the bracket.

(*b*) List *eight* items of information that should be included on a welding procedure sheet for the repair of the bracket.

(*c*) State *four* additional difficulties that would occur if the bracket has been made from 3% silicon alluminium alloy.

6 Give *three* reasons why hot cracking may be a problem when manual metal-arc welding austenitic stainless steel.

7 List *four* factors that should be considered when determining the pre-heating temperature to be used for welding a steel fabrication.

MATERIAL: CAST IRON

8 (*a*) A 30 mm thick alloy of the composition shown has to be manual metal-arc welded using rutile-coated electrodes.

Composition: 0.2% carbon; 2% chromium; 0.5% molybdenum; 0.8% manganese; 0.4% silicon; 0.35% sulphur; 0.035% phosphorus; remainder iron.

$$\text{Carbon Equivalent} = \%\text{C} + \frac{\%\text{Mn}}{20} + \frac{\%\text{Ni}}{15} + \frac{\%\text{Cr} + \%\text{Mo} + \%\text{V}}{10}$$

(1) Using the formula given calculate the carbon equivalent of the alloy.

(2) From the information given in the table below construct a graph and from it determine the pre-heating temperature of the alloy.

Carbon equivalent %	0.3	0.35	0.4	0.45	0.5	0.55	0.6
Pre-heat temp. (°C)	100	150	200	250	300	350	400

(3) If a hydrogen-controlled electrode is used to weld the material explain why the pre-heating temperature may be lowered by 100°C.

(*b*) Two of the hazards which may arise in welding are explosions and fumes. For any *one* of these state *four* possible causes and the precautions that should be taken to avoid them.

9 Brittle fracture may occur in welded structures in low-alloy steels.

(1) List *four* possible causes.

(2) State *four* precautions that should be taken in order to reduce its occurrence.

(3) Describe one test procedure which may be used to give information on the parent plate's susceptibility to this type of failure.

10 (*a*) Explain what is meant by percentage metal recovery in manual metal-arc welding.

(*b*) Electrode manufacturers claim that over 100% metal recovery is possible when using certain of their electrodes.

(1) State the addition which must be made to the coatings of these electrodes.

(2) State *two* advantages.

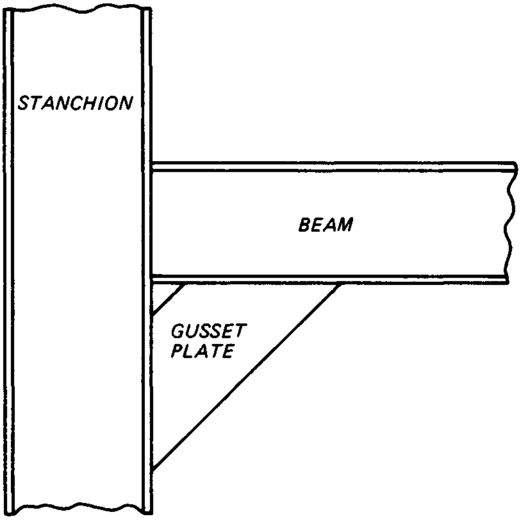
11 (*a*) State *two* factors that should be considered before selecting a filler electrode for a hard surfacing application.
(*b*) State *three* precautions which may be taken by the welder to control the level of dilution when surfacing using an arc welding process.

12 Steel components are to be hardfaced by the manual metal-arc process.
(*a*) Give *two* reasons why cracking may occur.
(*b*) State *three* precautions that can be taken in order to reduce the possibility of cracking.
(*c*) Name *one* other problem that may arise when hardfacing.

13 (*a*) With the aid of sketches, show *two* examples of distortion caused by manual metal-arc welding.
(*b*) For *each* example shown, suggest a suitable method of controlling the distortion.

14 The figure shows a typical beam-to-stanchion connection used in structural steelwork. Copy the drawing as shown and insert the appropriate welding symbols to indicate the following:
(*a*) the gusset to be fillet welded on each side to the stanchion in the shop;
(*b*) the beam to be added on site, and fillet welded all round to the stanchion;
(*c*) the gusset to be fillet welded each side to the beam.

Question 14



15 (*a*) Name two functions of the filter glasses used when metal-arc welding.
  (*b*) Why should the cable used for the welding lead connexion of an arc welding circuit be flexible?
  (*c*) Name two types of arc welding processes in which non-consumable electrodes are used.
  (*d*) Give one example of a semi-automatic arc welding process.

16 Name *four* different types of metal-arc welding plant which fulfil the electric power supply requirements for welding. Describe, with aid of a sketch, one of the plants named.

17 What would be the practical effect of each of the following during metal arc welding:
  (*a*) loose circuit connexions;
  (*b*) variations in the mains supply voltage?

18 Describe in detail, with the aid of sectional sketches, three defects which may be produced during the metal-arc welding in the horizontal–vertical position of close-square-tee joints in mild steel plate. In *each* case state the cause and explain how the defects should be avoided.

19 Explain briefly the effect of any two of the following upon the production of an efficient joint in a partially chamfered butt weld:
  (*a*) depth of root face,
  (*b*) the angle of the vee,
  (*c*) the gap setting.

20 Describe, with the aid of a sketch, one manual metal-arc welding technique used for making butt welds in mild steel pipelines.

21 Explain, by means of sketches, what is meant by *each* of the following:
  (*a*) The *slope and tilt* of the filler rod and blowpipe *when making* a butt weld in low-carbon steel, 2 mm thick, in the vertical position by the oxy-acetylene process.
  (*b*) The *slope and tilt* of the cutting electrode *when making* a straight cut in 8 mm low-carbon steel plate in the flat position by the oxygen-arc process.

22 (*a*) State *three* factors which may influence slag control during manual metal-arc welding.
  (*b*) Give *one* example of when each of the following are used in manual metal-arc welding:
    (1) tong test ammeter,
    (2) voltmeter.

23 (*a*) What is meant by (1) open circuit voltage, and (2) arc voltage in manual metal arc welding?

(*b*) State the likely effect on root penetration and weld deposit when manual metal-arc welding low-carbon steel 6 mm thick with too long an arc.

24 State *two* safety precautions which should be observed with *each* of the following for manual metal-arc welding:

(*a*) treating components prior to welding by the use of trichloroethylene degreasing plant,

(*b*) welding in confined spaces,

(*c*) welding in close proximity to glossy finished surfaces,

(*d*) preparing vessels which have contained liquids with flammable vapours for repair by welding.

25 (*a*) Sketch the joint set-up and state the diameter of electrodes and current values to be used when making butt welds in the flat position in *each* of the following thicknesses of low-carbon steel:

(1) 3 mm,
(2) 6 mm,
(3) 10 mm.
(4) 14 mm,

(*b*) Discuss the effect of *each* of the following factors on depth of root penetration when making butt welded joints in the flat position:

(1) current,
(2) arc length,
(3) speed of travel,
(4) angle of electrode (slope and tilt).

26 State why pre-heating is to be recommended when welded joints are to be made in *each* of the following:

(*a*) low-alloy, high-tensile steel in cold weather,

(*b*) 50 mm thick low-carbon steel,

(*c*) 6 mm thick copper plate.

27 The figure shows two views of a cast iron support bracket which has fractured in service.

(*a*) If the casting is to be replaced by a low-carbon steel welded fabrication:

(1) make a sketch showing the complete bracket assembled ready for welding. By the use of weld symbols (BS499) indicate the type and location of the weld joints;

(2) detail freehand the steel parts that you would require.

(*b*) If the casting is to be repaired by manual metal arc welding state:

(1) all preparations necessary to be made before welding;

(2) the weld procedure, including details of electrode and current values;

(3) any precautions to be carried out after welding.

28 Explain briefly why nickel is liable to crack when metal-arc welded. State briefly how this defect may be avoided.

29 With the aid of sketches, give two examples of distortion of welded work that may result from the application of metal-arc welding.

30 (*a*) Explain what is meant by the term 'arc eye'.

(*b*) What precautions should be taken to avoid 'arc eye'?

(*c*) What action should be taken in the case of severe 'arc eye'?

31 When each of the following materials is welded by the manual metal-arc process state, in each case, two difficulties which may arise:

(1) copper, (2) grey cast iron.

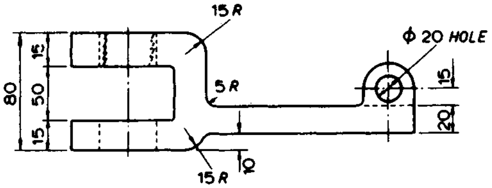
(*a*) State two difficulties which may be encountered when manual-metal arc welding dissimilar metals.

(*b*) Explain how these difficulties can be overcome.

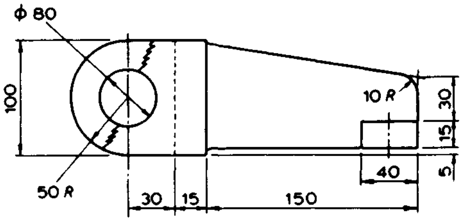
32 Give *three* precautions which should be taken to produce acceptable joints when manual metal-arc welding austenitic stainless steel. Butt welds are to be made in the construction of a pipe line.

(*a*) Give *two* reasons why excessive penetration should be avoided.

Question 27



ELEVATION



PLAN

(*b*) Describe briefly *two* methods of controlling root penetration.

33 Describe, with the aid of sketches, any *four* of the following. In *each* case state *one* typical application, *one* advantage and *one* limitation:

(*a*) stove pipe technique,
(*b*) tongue bend test,
(*c*) manipulators,
(*d*) arc on gas techniques,
(*e*) 'studding' when welding cast iron.

34 Describe, with the aid of sketches, each of the following:

(*a*) back-step welding,
(*b*) backing strips,
(*c*) backing bars.

35 The figure shows details of a pipe assembly. Answer the following:

(*a*) Recommend a suitable method in each case for producing to correct shape and size (1) the flanges, (2) the main pipe and the branch pipe.

(*b*) Describe, with the aid of sketches, a suitable edge preparation that may be used to ensure satisfactory penetration at the following joints: (1) a flange to the main pipe, (2) branch pipe to the main pipe.

(*c*) Show, with the aid of sketches, the procedure for welding both of these joints, stating the sequence of runs, the current value and diameter of electrode used in each case.

(*d*) Describe briefly how the finished welds may be tested for surface defects.

36 The figure shows details of a pipe assembly. Answer the following:

(*a*) Show, by means of a sketch, how the main pipe and the flanges may have distorted as a result of welding.

(*b*) Sketch a simple fixture that would be suitable for locating the branch to the main pipe and assist in controlling distortion.

(*c*) Describe briefly a suitable method for pressure testing the completed assembly.

(*d*) Calculate the total weight of the three flanges; 1 m^3 of low-carbon steel weighs 7750 kg.

37 Briefly explain the function of *each* of the following in manual metal-arc welding:

(*a*) a low-voltage safety device,
(*b*) a rectifier.

38 (*a*) What are the *three* basic types of wear to which hard-faced components are subjected?

(*b*) Select *one* of these types and suggest a suitable type of electrode to be used for surfacing to meet requirements.

(*c*) State *two* precautions which should be taken to minimize cracking.

39 An aluminium alloy casting is to be repaired by the manual metal-arc welding process. Give *each* of the following:

(*a*) a workshop method of indicating the pre-heating temperature,

(*b*) the type of current to be used.

(*c*) *three* factors which make this material more difficult to weld than low-carbon steel.

40 Select a suitable electrode for welding *each* of the following low-carbon steel joints:

(*a*) a severely stressed single-vee butt joint welded in the flat position,

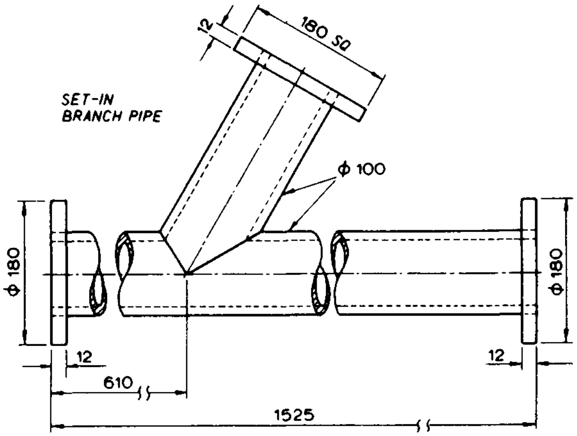
(*b*) a lightly stressed fillet welded joint in the vertical position,

(*c*) fillet welds in the flat position where a high metal recovery rate is required.

41 State one important safety precaution that must be observed for each of the following:

(*a*) before commencing welding repair work on a two-compartment tractor fuel tank, having one compartment used for petrol and the other for fuel oil;

Question 35 and 36



(*b*) when flame gouging in the vertical position a defective vertical joint out of a heavy fabrication in preparation for rewelding.

42 State *two* advantages which may be obtained by the use of a U preparation instead of a V preparation for welded butt joints in thicker materials.

43 Sketch the joint preparation and set-up, and state the size of the electrodes, number of runs and current values to be used for making
- (1) butt welds, without backing bar in the flat position,
- (2) tee fillet welds in the horizontal–vertical position, in each of the following thicknesses of mild steel: 6.4 mm and 12.7 mm.

44 State the plate thickness limitations of the upward–vertical and the downward–vertical metal arc welding techniques.

45 (*a*) Describe, with the aid of sketches, what effect each of the following would have on the depth of root penetration and the quality of the deposited metal:
- (1) the use of too high current value,
- (2) incorrect angle of electrode slope,
- (3) too fast a speed of travel,
- (4) incorrect arc length.

(*b*) Explain how measuring equipment could be used to check current and voltage values available in a metal arc welding circuit during welding.

46 State one safety precaution that must be carried out:
- (*a*) before commencing welding repair work on a tank which has contained acids,
- (*b*) when metal arc welding from a multi-operator set is carried out during the construction of multiple-storey steel framed structures.

47 State what is meant by:
- (*a*) deep-penetration coated electrode,
- (*b*) non-consumable electrode.

48 What is the purpose of a choke reactance used in manual metal arc welding?

49 (*a*) What is meant by arc blow in manual metal arc welding?

(*b*) Arc blow may arise when manual metal arc welding with either direct current or alternating current supply. Give *two* possible causes.

50 (*a*) State what is meant by:
- (1) rutile-coated electrode,
- (2) hydrogen-controlled coated electrode.

(*b*) Give *one* defect which may arise when manual metal arc welding low-carbon steel, using an eccentrically coated electrode.

51 Describe with the aid of sketches the *technique* required when cutting low-carbon steel plate in the flat position by the use of *each* of the following arc cutting processes:
(1) air-arc,
(2) oxygen-arc.

52 Sketch and label *two* different types of edge preparation for butt joints other than close-square butt, suitable for manual metal arc welding.

53 Give *one* possible cause of *each* of the following defects when manual metal arc welding close-square-tee fillet joints in low-carbon steel in the vertical position by the upwards technique:
(*a*) incomplete root penetration,
(*b*) undercut,
(*c*) unequal leg-length.

54 (*a*) Explain what is meant by 'percentage metal recovery' in metal arc welding.
(*b*) If over 100% is claimed, what additions could have been made to the electrode coating?

55 Manufacturers of metal arc welding electrodes take care to specify a minimum and maximum current for each size and type of mild steel electrode. Discuss in detail the important consequences of using
(*a*) insufficient current,
(*b*) excessive current.

56 (*a*) State *three* reasons for using welding fixtures in welding fabrication.
(*b*) State *three* basic factors that must be considered for the effective operation of a welding fixture.
(*c*) Describe briefly, with the aid of a sketch, the principle of operation of any welding fixture with which you are acquainted.

57 A number of butt welded joints have to be made between the ends of 100 mm diameter low-carbon steel pipe. Sketch a simple jig for holding them in position for tack welding.

58 Give *four* important functions of a slag.
(*a*) Briefly describe one test, other than visual inspection, used to reveal surface defect in welded joints.
(*b*) Give one limitation of such a test.
(*c*) Name four constituents used in electrode coatings.

(*d*) State the most important function of any one of these constituents.

59 Give *four* differences in the behaviour of the metal that a welder will find between the metal arc welding of (*a*) aluminium and (*b*) low-carbon steel.

60 (*a*) Describe in detail the metal arc welding process commonly used for manually welding mild steel.

(*b*) Give *two* examples showing how the process in (*a*), using standard electrodes, may be partially automated so as to reduce costs.

61 State *three* factors that may influence metal transfer phenomena when using a metal arc welding process.

62 Give *three* reasons why stray-arcing is undesirable.

63 Give *three* reasons why damp flux-coated electrodes should not be used for welding mild steel.

64 With the aid of a sketch, show the principle of the buttering technique.

65 (*a*) Construct a table showing the ranges of welding currents typically used with 2.5 mm, 3.2 mm, 5.0 mm and 6.0 mm general-purpose, mild steel electrodes.

(*b*) Plot a graph from the figures in the table in part (*a*).

(*c*) From the graph in part (*b*) determine the probable current range to be used with a 4.0 mm electrode.

66 State *three* safety precautions to be observed when using engine-driven metal arc welding equipment.

67 Give any *two* advantages of using multi-operator a.c. metal arc welding equipment.

68 The figure shows two views of a bracket which has to be fabricated by manual metal arc welding.

(*a*) Make a pictorial sketch of the bracket and indicate, by the use of weld symbols, according to BS499, the location and the type of weld joints required.

(*b*) List *ten* items of information that could be included on a Welding Procedure Sheet for the bracket shown.

69 The figure shows two views of a cast iron bracket which has fractured in service.

(*a*) If the casting is to be repaired by manual metal arc welding,

(1) state *all* preparations necessary to be made before welding,

(2) describe a suitable procedure, including details of the type of electrodes and the current values,

(3) state *two* precautions carried out after welding.

(*b*) Make a sketch to show the complete bracket assembled ready for welding, if the casting is to be replaced by a low-carbon steel welded fabrication. By the use of weld symbols (BS499), indicate the type and location of the weld joints to be used.

70 Give *one* reason why, in particular situations, it might be difficult to control the arc when arc welding mild steel.

71 Give what you consider to be *three* important factors likely to affect the cost of the welded fabrication of a very large one-off component.

72 (*a*) By means of a labelled sketch show what is meant by buttering.

(*b*) Name *one* material on which buttering could helpfully be used to make an effective arc fusion welded joint.

73 Explain how the difficulties which may arise from the presence of hydrogen may be overcome during the welding of low-alloy steels.

74 What is an alloy? Give *two* reasons why an alloying addition might be necessary in the composition of a metal intended for use as weld metal for joints to be made by gas-shielded arc welding.

Gas shielded metal arc MIG *and* TIG

1 (*a*) List *four* welding problems to be overcome when gas-shielded metal-arc welding austenitic heat-resisting steels to be used for high-temperature service.

(*b*) State *three* features which should be present in a manipulator intended for extensive gas-shielded metal-arc welding of joints in a large assembly.

(*c*) Outline *three* functions of jigs designed to be used for the metal-arc gas-shielded welding of joints in components during flow production.

2 (*a*) State *five* factors which influence the cost of metal-arc gas-shielded welding in the batch production of welded fabrications in non-ferrous metals.

(*b*) A butt welded joint in a flat, low-carbon steel bar L mm wide and t mm thick is to be made by the metal-arc gas-shielded process. When in service a static tensile load of P newtons will be carried by the butt welded joint. Show by means of a simple formula how the tensile stress in the butt weld may be calculated.

(*c*) Describe, with the aid of sketches, a technique which may be used for making a fillet welded part-lapped close outside corner joint in the flat position in 6 mm thick aluminium plate by the metal-arc gas-shielded process.

3 (*a*) With the aid of a labelled block diagram to show the arrangement, describe the equipment necessary to fulfil the electrical gas-shielding and ancillary requirements when one operator is required to carry out effective tungsten-arc gas-shielded welding with
  (1) alternating current,
  (2) direct current as required for different types of material.
(*b*) State the purpose of *each* item of equipment in the system and give details of current control together with a labelled sketch to show the power source characteristic.

4 (*a*) State *four* different-types of material suitable for tungsten-arc gas-shielded welding.
(*b*) In the case of *two* of these materials state
  (1) *two* difficulties that may arise during the welding of the material,
  (2) the methods used to overcome the difficulties encountered.

5 (*a*) List *four* gases *or* gas mixtures used in tungsten-arc welding and give *one* typical application of *each.*
(*b*) Describe with the aid of sketches, a technique used for making a close-square butt joint in the vertical position by the upward method in 2.5 mm thick austenitic stainless steel by the tungsten-arc process.
(*c*) State *four* possible causes of incomplete penetration when making butt welds by the tungsten-arc process in the flat position.

6 (*a*) Outline *two* essential functions of the gas shield required for effective gas-shielded metal-arc welding.
(*b*) List *four* gases *or* gas mixtures, other than carbon dioxide, used in metal-arc gas-shielded welding and give *one* typical application of *each.*
(*c*) State *two* possible causes of *each* of the following defects when encountered in welds made by the metal-arc gas-shielded process in low alloy steel:
  (1) porosity,
  (2) cracking.
(*d*) Explain why care should be taken to avoid leakage at joints in the shielding gas supply lines when gas-shielded metal-arc welding aluminium alloys.

7 (*a*) Show, by means of a labelled diagram, the voltage waveform obtained when using *either* a high-frequency unit *or* a surge injector for gas-shielded tungsten-arc welding with alternating current supply.

(*b*) State the function of each of the regularly alternating high and low current levels used in controlled spray (pulse) mode of metal transfer in gas-shielded metal-arc welding.

8 (*a*) Outline *one* method of arc length control which may be used in metal-arc gas-shielded welding.

(*b*) Show, by means of labelled sketches, the stages in spray mode of metal transfer when metal-arc gas-shielded welding.

9 (*a*) Explain, with the aid of a sketch, how the level of dilution of a butt-welded joint may be determined.

(*b*) Show by means of a labelled sketch *one* type of edge preparation used to control pick-up effects when making a butt-welded joint in clad steel.

10 The following gas shielding mixtures are used in gas-shielded arc welding:

(*a*) argon,
(*b*) argon and hydrogen,
(*c*) argon and oxygen,
(*d*) argon and nitrogen,
(*e*) argon and helium.

State, in *each case*, a material and the welding process for which these mixtures are best suited.

11 (*a*) Name the type of current and electrode required for gas-shielded tungsten-arc welding *each* of the following materials:

(1) low-carbon steel,
(2) aluminium alloy,
(3) copper alloy.
(4) austenitic stainless steel.

(*b*) State *two* factors, other than thickness of material, which should be considered when selecting the filler wire diameter to be used for tungsten-arc welding.

12 (*a*) Outline the procedure for rectifying a fault which has been indicated in a metal-arc gas-shielded welding circuit by failure to strike an arc and a falling voltage reading at the power source.

(*b*) Show, by means of a sectional sketch, the contact tube setting and electrode extension required for dip transfer welding of low-carbon steel.

13 (*a*) Sketch a tungsten-arc welding torch fitted with a gas lens and increased electrode extension, indicating the pattern of gas flow which would be obtained from the torch.

(*b*) State *two* reasons why rectification must be controlled when alternating current is used for the gas-shielded tungsten-arc welding of aluminium.

14 (*a*) State *two* safety precautions, other than ventilation, which are necessary when using gas-shielded arc welding processes.

(*b*) State how
   (1) ozone,
   (2) carbon monoxide
may be formed during gas-shielded arc welding.

15 (*a*) State the purpose of a choke reactance when used for gas-shielded metal-arc welding.

(*b*) State the function of
   (1) a surge injector,
   (2) a high frequency unit,
when tungsten arc welding with alternating current.

16 Show by means of a labelled diagram of output curves the essential differences between the characteristics of the power source suitable for

(*a*) manual tungsten-arc gas-shielded welding,
(*b*) semi-automatic metal-arc gas-shielded welding with a self-adjusting arc.

17 (*a*) State what current values are being shown by the ammeter when welding with controlled spray (pulse) mode of metal transfer.

(*b*) Show, by means of labelled sketches, the stages in metal transfer when metal-arc gas-shielded welding by means of dip mode of metal transfer.

18 State, in *each* case, *two* precautions which must be taken in the storage of

(*a*) electrode wires for metal-arc gas-shielded welding,
(*b*) filler wires for tungsten-arc gas-shielded welding,

to ensure effective welding when required.

19 (*a*) During gas-shielded tungsten-arc welding, porosity has appeared in the weld face and metal deposition has become difficult. State *two* possible causes that may produce this condition.

(*b*) Give *one* suitable material in *each* case which may be used for a backing bar insert when tungsten-arc gas-shielded welding
 (1) ferrous metals,
 (2) non-ferrous metals.

20 (*a*) Give *two* undesirable effects which may occur when using excessive wire feed speed during gas-shielded metal-arc welding.

(*b*) State the shielding gas or gas mixture which is best suited to obtain the required modes of metal transfer for the efficient metal-arc gas-shielded welding of *each* of the following metals:
 (1) low-carbon steel and low-alloy steel by spray transfer in the flat position,
 (2) austenitic stainless steel and aluminium by controlled spray (pulse) transfer in the vertical position.

21 (*a*) State how gas flow rate is controlled and measured to enable the production of efficient welded joints in tungsten-arc gas-shielded welding.

(*b*) Name *four* factors upon which the selection of the correct current value will depend in tungsten-arc welding.

22 (*a*) Give *two* advantages which may be obtained by the use of the metal-arc gas-shielded spot welding process instead of the electric resistance spot welding process.

(*b*) State *one* typical application in each case for the following welding process:
 (1) electron beam,
 (2) friction.

23 (*a*) Outline the procedure for rectifying a fault which has been indicated in a metal-arc gas-shielded welding circuit by failure to strike an arc and a falling voltage reading at the power source.

(*b*) Show, by means of a sectional sketch, the contact tube setting and electrode extension required for dip transfer welding of low-carbon steel.

24 (*a*) Sketch a tungsten-arc welding torch fitted with a gas lens and increased electrode extension, indicating the pattern of gas flow which would be obtained from the torch.

(*b*) State *two* reasons why rectification must be controlled when alternating current is used for the gas-shielded tungsten-arc welding of aluminium.

25 Explain why the presence of moisture should be avoided when gas-shielded arc welding low-alloy steels.

26 (*a*) State in *each* case *one* probable cause of the following weld defects in joints made by tungsten-arc welding:
(1) lack of root penetration,
(2) porosity.

(*b*) State *two* reasons why abrupt changes of section should be avoided in the contours of a welded joint.

27 (*a*) Outline *two* essential functions of the gas shield required for tungsten-arc welding.

(*b*) State *two* factors which influence the selection of the flow rate of argon gas necessary to obtain efficient welded joints.

(*c*) State in *each* case *two* difficulties that may arise during the tungsten-arc welding of
(1) stainless steel,
(2) aluminium,
(3) magnesium alloy.

28 (*a*) Describe, with the aid of a sketch, the distortion effects which are likely to be produced when an unrestrained 450 mm long single-vee butt joint between 6 mm thick austenitic stainless steel plates 225 mm wide is made by the tungsten-arc process in two runs from one side.

(*b*) Give *two* methods used to control distortion.

(*c*) Outline, with the aid of sketches, *two* methods of providing gas backing for the butt welding of pipe joints.

29 (*a*) Outline the shut-down procedure to be followed at the end of work with tungsten-arc welding plant in order to ensure safety and continued efficiency of equipment.

(*b*) Show, by means of a labelled sketch, the gas paths and the function of *each* of the main components of a water-cooled tungsten-arc welding torch.

(*c*) Describe, with the aid of sketches, a tungsten-arc technique used for making a close-square butt-welded joint in the vertical position by the upward method in 1.5 mm thick austenitic stainless steel.

30 (*a*) Describe, with the aid of a labelled block arrangement diagram, the purpose of each part of the equipment essential for argon-shielded metal-arc welding aluminium alloys.

(*b*) State *one* precaution which must be taken with the temporary backing bars used in welding aluminium alloys in order to ensure the production of efficient joints.

(*c*) State the shielding gas or gas mixture which is most suited to obtain controlled spray (pulse) mode of metal transfer for welding
  (1) low alloy steel,
  (2) aluminium.

31 (*a*) List *four* welding problems to be overcome when welding steel containing 9% nickel, which is to be used for low-temperature service.

(*b*) State *three* features which should be present in a jig designed for use in the welding of joints made in components during batch production.

(*c*) Describe, with the aid of sketches, a gas-shielded metal-arc technique which may be used for making a lap-fillet welded joint in the vertical position by the downward method in 3 mm thick low-carbon steel plate.

32 (*a*) List *three* advantages and *three* disadvantages in *each* case which may be obtained by the use of
  (1) carbon dioxide,
  (2) argon,
for metal-arc gas-shielded welding.

(*b*) Outline *two* effects of the chromium content on the weldability of low-alloy high-tensile steel.

(*c*) State *two* essential factors which must be considered before making welded joints between dissimilar metals by the metal-arc gas-shielded welding process.

33 (*a*) Give *two* reasons why it is necessary to be particularly careful with the insulation of components in the welding circuit when using high-frequency current in tungsten-arc gas-shielded welding operations.

(*b*) Give *two* safety precautions which should be taken when preparing to use the metal-arc gas-shielded welding process for making welds on site in an exposed position which is 12 metres above ground level.

34 (*a*) State the purpose of a drooping voltage transformer-rectifier when used for tungsten-arc gas-shielded welding.

(*b*) Outline *two* methods used to control the current surges at the short-circuitings which take place when metal-arc gas-shielded welding with dip mode of metal transfer.

35 (*a*) Explain what is meant by *each* of the following in fusion welding:
  (1) dilution,
  (2) pick-up.

(*b*) Show by means of a labelled sketch *one* type of joint preparation used to control pick-up effects when making a butt-welded joint in clad steel.

36 (*a*) State *two* reasons why the d.c. component must be suppressed when alternating current is used for gas-shielded tungsten-arc welding.

(*b*) Outline, with the aid of a sketch, *one* method of providing back purging for the butt welding of a joint in flat plate by the tungsten-arc process.

37 (*a*) State *one* undesirable effect in *each* case which is likely to be produced when metal-arc gas-shielded welding with wire feed drive roll pressure adjustment which is

(1) insufficient,
(2) excessive.

(*b*) Give *four* routine checks which should be made on the electrode wire before fitting a new spool into a gas-shielded metal-arc welding plant.

38 Distortion may result from gas-shielded arc welding operations. State *two* possible causes and give *two* methods of control.

39 (*a*) Give *one* reason in *each* case for the use of

(1) a remote control switch,
(2) a welding contactor,

in tungsten-arc welding.

(*b*) State the likely effect of allowing cables in the welding circuit to coil when using high-frequency currents in gas-shielded tungsten-arc welding.

40 (*a*) Explain the technique to be followed to avoid contamination of the electrode when tungsten-arc welding butt joints in thicker section material in the flat position.

(*b*) Give *two* advantages which may be obtained by the use of the two-operator upward-vertical technique for tungsten-arc welding.

41 (*a*) Give *two* reasons why flux-cored electrode wire is used with carbon dioxide shielding for the metal-arc gas-shielded welding of steel.

(*b*) When using a gas-shielded arc welding process, on an exposed site, which *two* problems are most likely to be encountered as a result of weather conditions?

42 (*a*) What advantageous feature is provided by a constant potential power source when the arc is initiated to start the weld in metal-arc gas-shielded welding?

(*b*) Outline the procedure for rectification when a fault condition has been indicated in a metal-arc gas-shielded welding circuit, by falling voltage reading at the power source, when the end of the electrode wire is touched on to the work with the torch control trigger actuated.

43 Name *four* factors which may affect the cost of metal-arc gas-shielded welding a fabrication in a non-ferrous alloy.

44 With the aid of a sketch, explain briefly the principles of the tungsten-arc spot welding process.

45 (*a*) Describe, with the aid of a sketch, the distortion effects which are likely to be produced when an unrestrained 300 mm long single-vee butt joint between 5 mm thick austenitic stainless steel plates, 150 mm wide, is made in two runs from one side by the tungsten arc process.

(*b*) Outline *two* methods used to control distortion in tungsten-arc welding operations.

46 List *four* of the main welding problems encountered when tungsten-arc gas-shielded welding magnesium alloys in thicknesses ranging from 2 mm to 10 mm, indicating how *each* of these problems is overcome, and mentioning the effects of surface preparation.

47 Twenty 2 metre pipe lengths are to be fabricated from existing stock of 1 metre lengths of 150 mm internal diameter low-carbon steel pipe of 10 mm wall thickness by metal-arc gas-shielded welding. Describe, with the aid of sketches, *each* of the following for the welding of one joint:

(*a*) a suitable joint preparation and set-up,
(*b*) the assembly and tack welding procedure,
(*c*) the mode of metal transfer, shielding gas and electrode wire size to be used,
(*d*) an effective welding procedure.

48 (*a*) Compare the use of carbon dioxide with the use of argon for metal-arc gas-shielded welding by listing *two* relative advantages and *two* relative disadvantages which may be obtained by the use of *each* gas.

(*b*) State *two* advantages which may be obtained by the use of a manipulator as an aid to fabrication by metal-arc gas-shielded welding.

49 State the sequence which could be used to complete the joints numbered 1, 2, 3, and 4 in the figure of a welded fabrication made from five parts as shown. Give reasons for your answer.

50 For joint 1 in the figure give details of (*a*) the type of preparation and (*b*) the welding procedure to be used.

51 For joint 2 in the figure give details of (*a*) the type of preparation and (*b*) the welding procedure to be used.

52 Describe briefly four problems which may be encountered in the welding of the fabrication shown in the figure.

53 State why a self-adjusting arc is 'not likely to operate effectively in CO_2 shielded metal-arc welding'.

54 By means of a labelled block diagram show clearly the equipment required to give effective control of gas flow to the torch or welding head during gas-shielded arc welding. Assume that a suitable gas is being used.

55 By means of a labelled sketch indicate any *three* types of weld defect likely to occur in gas-shielded arc welded joints.

56 What is the purpose of a suppressor unit in a gas-shielded arc welding circuit?

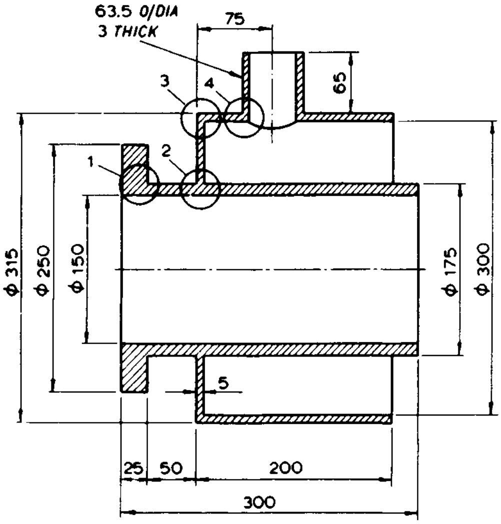
57 State *three* different types of material suitable for tungsten arc gas-shielded welding. In *each* case state

(*a*) two difficulties that may arise during the welding of the material,

(*b*) the methods used to overcome the difficulties encountered.

58 With the aid of a simple labelled block diagram show the name, location and purpose of each part of the equipment essential for the effective tungsten-arc gas welding of aluminium.

Questions 49–52. Section through a heater shield. Material: 18% Cr, 8% Ni austenitic steel, Ti stabilized. Process: gas-shielded tungsten arc welding.



59 (*a*) Sketch a tungsten-arc welding torch fitted with gas lens, indicating the pattern of gas flow which would be obtained from the torch.

(*b*) State *two* advantages which may be obtained by the use of a gas lens in tungsten-arc welding.

60 (*a*) Describe briefly the recommended procedure to follow for clearing a 'burn back' in gas-shielded metal-arc welding.

(*b*) State *four* causes, other than joint preparation, of lack of root penetration in butt-welded joints made by gas-shielded metal-arc welding.

61 (*a*) Outline the typical main functions of a jig or fixture suitable for use in tungsten-arc gas-shielded welding.

(*b*) Give *two* situations in which the use of a jig or fixture would be considered essential, in the manufacture of a component by tungsten arc gas-shielded welding.

62 Explain what is meant by gas-backing in tungsten-arc welding and show *two* ways in which it may be applied.

63 List *two* advantages and *two* limitations of gas-shielded metal-arc welding as a process for general-purpose welding repair work.

64 With the aid of a simple labelled block diagram show the name, location and purpose of each part of the equipment essential for the effective CO_2 shielded metal-arc welding of low-carbon steels.

65 State *four* features which should be present in a manipulator intended for extensive gas-shielded metal-arc welding of joints in a large component.

66 (*a*) State the type of filter which should be used to provide eye and skin protection against radiation effects when gas-shielded arc welding with:

(1) the tungsten arc process,
(2) the metal arc process.

(*b*) Give *one* reason, in *each* case, for the type of filter used.

67 (*a*) What is the purpose of a choke reactance when used for gas-shielded metal-arc welding?

(*b*) State *two* effects which may be produced by using excessive electrode wire extension during welding.

68 (*a*) Give *two* advantages of tungsten-alloyed electrodes over plain tungsten electrodes when used for tungsten-arc welding.

(*b*) Show by means of simple labelled sketches what is meant by the electrode tip (vertex) angle when tungsten-arc welding with:

(1) alternating current,
(2) direct current.

69 Show by means of a single labelled sketch the essential differences between welding power source characteristics suitable for:
(*a*) manual tungsten-arc welding,
(*b*) welding with a self-adjusting arc.

70 (*a*) State *two* factors which influence the amount of dilution of the weld deposit in gas-shielded arc welding.
(*b*) With the aid of an outline sketch, show how the level of dilution of the welded joint may be determined.

71 (*a*) State *two* modes of metal transfer, other than spray, used for gas-shielded metal-arc welding.
(*b*) Give *one* application of *each* mode of transfer named.

72 (*a*) Give *two* important physical properties of ceramic gas nozzles.
(*b*) State *two* of the factors which govern the gas-shielding necessary to obtain efficient welded joints by tungsten-arc welding.

73 (*a*) State the type of current and tungsten alloyed electrode recommended to be used for tungsten-arc welding *each* of the following materials:
(1) low-carbon steel up to 2 mm thick,
(2) austenitic stainless steel up to 5 mm thick,
(3) aluminium over 3 mm thick,
(4) magnesium alloy up to 5 mm thick.
(*b*) List *three* gases or gas mixtures in tungsten-arc welding and give one typical use of each.

74 (*a*) State *four* factors that have to be taken into account when costing for tungsten-arc gas-shielded welding.
(*b*) Explain what is meant by:
(1) arcing time,
(2) floor to floor time.

75 (*a*) List the main welding problems when tungsten-arc gas-shielded welding copper plates in thicknesses ranging from 3 to 10 mm.
(*b*) Outline with the aid of sketches how each of these problems may be counteracted.

76 (*a*) Show by means of a labelled sketch *one* method of providing gas backing for the tungsten-arc welding of butt joints in plate in the flat position.
(*b*) Why should syphon-type cylinders be used to supply carbon dioxide for shielding gas in welding?

77 With the aid of simple sketches show how you would prepare the joints for welding the top central part of the beam shown in the

figure, where the central boss and the top flange join with each other and where the vertical web joins with the top plate.

78 State the welding sequence which should be used for welding the beam shown in the figure. Give reasons for each step.

79 Describe four of the problems which are likely to arise in welding the ends of the beam shown in the figure.

80 On a sketch of the figure give all the information needed to show the type and location of each welded joint, using the system given in BS 499 (Part 2).

81 Give *three* reasons why a suitable shade of filter glass should be used for viewing the arc during gas-shielded arc welding.

82 The following gas-shielding mixtures are used in gas-shielded arc welding:

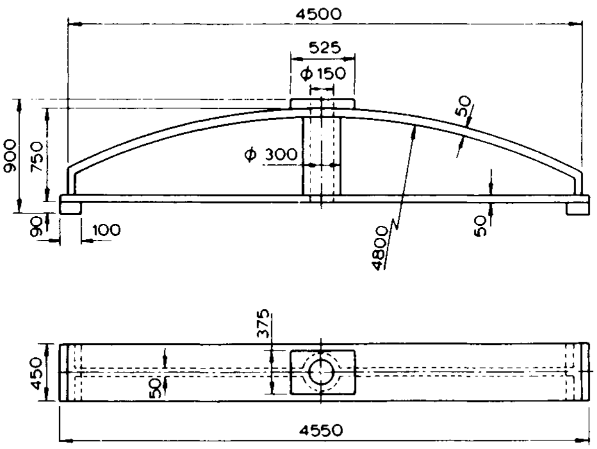
(*a*) argon + carbon dioxide + oxygen,
(*b*) argon + oxygen,
(*c*) argon + hydrogen,
(*d*) helium + argon,
(*e*) helium + argon + carbon dioxide.

State in *each* case:

(1) the material for which the mixture is best suited,
(2) the approximate percentages of gases in the mixture.

83 State *five* desirable features in jigs intended for gas-shielded metal-arc welding of joints in components to be mass produced.

Questions 77–80. Support beam. Material: high yield stress structural steel (BS 4360 Grade 50) welded by CO_2 shielded metal arc process.



84 (*a*) With the aid of a labelled block diagram to show the arrangement, describe the purpose of *each* part of the equipment necessary for the effective argon-shielded metal-arc welding of aluminium alloys.

(*b*) State *one* precaution which must be taken in *each* case, with:

(1) the shielding gas supply lines,
(2) temporary backing bars,

in order to assist in the production of efficient joints.

85 (*a*) Give *one* safety precaution to be taken before tungsten-arc gas-shielded welding when the gas cylinder is located near the welding area.

(*b*) Give *two* hazards present when metal arc gas-shielded welding equipment is inadequately earthed.

86 (*a*) State the purpose of a combined transformer-rectifier when used for tungsten-arc welding.

(*b*) Give *two* important reasons for the use of a welding contactor in tungsten-arc welding.

87 (*a*) State the type of current and tungsten alloyed electrode recommended to be used for tungsten-arc welding *each* of the following materials:

(1) low-carbon steel up to 2 mm thick,
(2) austenitic stainless steel up to 5 mm thick,
(3) aluminium over 3 mm thick,
(4) magnesium alloy up to 5 mm thick.

(*b*) List *three* gases or gas mixtures in tungsten-arc welding and give one typical use of each.

88 (*a*) State the purpose of a surge injector unit as used in arc welding.

(*b*) State the purpose of a suppressor unit as used in arc welding.

89 A cylindrical vessel 620 mm diameter by 2.5 metres long with low-carbon steel flanged ends 25 mm thick is to have two austenitic stainless steel pipes coming out at right angles to the vessel axis and to each other midway along the vessel axis. The pipes are 100 mm inside diameter with a wall thickness of 9.5 mm and the vessel is made of 12.5 mm thick low-carbon steel, clad inside with austenitic steel to a further 1.6 mm thickness. The pipes and flanges are to be joined to the vessel by gas-shielded tungsten-arc welding.

(*a*) Give particulars of (1) the type of joint, (2) the joint preparation and (3) the welding procedure that you recommend for the welding of flanges to the vessel.

(*b*) Give particulars of (1) the type of joint, (2) the joint preparation and (3) the welding procedure that you recommend for welding the pipes into the vessel.

90 A special I-section girder 6 metres long has the following sectional dimensions: flanges 450 mm wide by 50 mm thick, web 19 mm thick, and overall depth 1 metre. Stiffening ribs 150 mm wide by 12.5 mm thick, running from flange to flange, are located opposite each other against the web at right angles to the rider axis at 1.2 m intervals. The girder is to be fabricated from high-tensile constructional steel of welding quality by gas-shielded metal-arc welding.

(*a*) Give particulars of (1) the type of joint, (2) the joint preparation, and (3) the welding procedure that you would use for joining the web to the flanges.

(*b*) Give particulars of (1) the type of joint, (2) the joint preparation, and (3) the welding procedure that you would use for attaching the stiffening ribs.

91 There are particular economic and metallurgical problems associated with the effective use of gas-shielded metal-arc welding in production applications. Outline these problems and explain how they may be overcome.

92 Austenitic heat-resisting steels containing higher nickel and chromium contents are used for fabricating structures for high-temperature service.

(*a*) State *five* main welding problems that are likely to arise in the metal-arc gas-shielded welding of this type of material.

(*b*) Explain how *each* of these problems may be effectively overcome to ensure efficient welded joints for service at high temperatures.

93 (*a*) When a d.c. arc is operating, what proportion of the heat may be generated at each side of the arc?

(*b*) Would the heating situation be the same when tungsten-arc gas-shielded welding aluminium with the electrode positive?

94 A gas pressure regulator and a flowmeter are each essential for the successful operation of a gas-shielded arc welding process.

(*a*) With the aid of an outline diagram show the usual location of each in a conventional gas-shielded tungsten-arc welding arrangement.

(*b*) Why is it necessary to have a gas pressure regulator?

95 In gas-shielded tungsten-arc welding each of the following plays an important part: (1) length of electrode projecting beyond the nozzle, (2) length of arc, (3) angle of electrode relative to the workpiece.

Give *two* important reasons why small diameter filler wire is used for gas-shielded metal-arc welding.

96 (*a*) State one difficulty with the dip-transfer mode of metal deposition as it is used in CO_2 shielded metal-arc welding.

(*b*) State briefly how this difficulty is overcome.

97 On a simple labelled block diagram show the name and purpose of each essential part of the plant and equipment needed for making tungsten-arc gas-shielded welds in a variety of metals and a range of thicknesses.

98 Give two checks you should make on the electrode wire before fitting a new spool into a gas-shielded metal-arc welding machine.

99 Why is a double-bevel or a double J butt-welded tee joint preferable to a double fillet welded close-square-tee joint for welding two highly stressed members?

100 (*a*) Explain why, in spite of the overall efficiency of argon as a shielding gas, so much effort is spent in developing the use of gases such as carbon dioxide.

(*b*) Name two difficulties likely to be encountered in using carbon dioxide as a shielding gas in arc welding.

(*c*) For each of the difficulties given in your answer to (*b*) name one method used for overcoming the problem.

101 State the main difficulty you would expect to have to overcome in joining each of the following types of material by gas-shielded tungsten-arc welding:

(*a*) malleable cast iron,

(*b*) solution-treatable aluminium alloy.

102 (*a*) Name any *two* limitations of the gas-shielded tungsten-arc welding process.

(*b*) Name any *two* limitations of the gas-shielded metal-arc welding process.

(*c*) Why is a gas shield needed in the two types of arc processes in which it is used?

103 (*a*) In tungsten-arc welding how should the welding arc be initiated without contact between electrode and parent metal?

(*b*) With the aid of a simple line diagram show all the essential equipment for the conditions that you outline in (*a*) and clearly label each part.

104 (*a*) With the aid of sketches show how a single-vee butt joint preparation for tungsten-arc welding should differ from that of gas-shielded metal-arc welding in the same thicknesses of similar materials.

(*b*) Give the main reason why they should differ.

105 The support column shown in the figure is to be made up from 25 mm thick plates of high-strength low-alloy structural steel mounted on a square mild steel base plate. The sizes are given on the diagram.

(*a*) Outline the main material problems to be overcome in welding this construction.

(*b*) Indicate where you would locate the four transverse joints required to make up the vertical member from the two plates.

106 For the support column shown in the figure and the materials quoted in question, give

(*a*) the details of the appropriate longitudinal joint preparation used to complete the hollow section,

(*b*) the number and sequence of deposition of the runs required to complete the section,

(*c*) any precautions necessary to ensure sound welds.

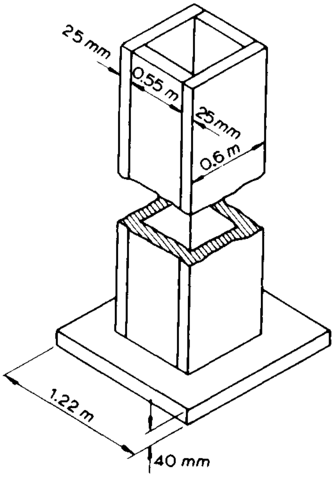
107 For the support column shown in the figure and the materials quoted in question, give

(*a*) the details of the appropriate joint preparations used to attach the vertical member to the base,

(*b*) the number and sequence of deposition of runs used to complete this joint,

(*c*) any precautions necessary to ensure sound welds.

Questions 105–108. Overall height 5.6 m. Material available for main stem: plate 3.5 m × 1.2 m × 25 mm, plate 2.0 m × 1.2 m × 25 mm.
Note. Gas shielded metal arc welding to be used for all except tack welds.



108 Discuss the main factors affecting the desirability of making up a special welding fixture for use when making the longitudinal welds in the vertical member of the support column shown in the figure.

109 (*a*) Give *two* reasons why it is necessary to be particularly careful of plant insulation when using HF current.
   (*b*) Why may it be dangerous to weld with an exposed arc near to a tank filled with non-flammable degreasing liquid?

110 (*a*) Give the principle reason why carbon dioxide gas is used for the gas-shielded metal-arc welding of mild steel.
   (*b*) Give *one* specific difficulty to be overcome when using carbon dioxide as a shielding gas for arc welding mild steel.

111 With the aid of an outline sectional sketch show the relative positions and proportions of (*a*) the electrode, (*b*) the collet, (*c*) the gas entry and (*d*) the nozzle, in a typical gas-shielded tungsten-arc welding torch head.

112 On a simple outline sketch locate and name the function of any *three* parts essential to the operation of the welding head of a fully automatic gas-shielded metal-arc welding plant.

113 Give any *three* possible differences between the respective preparation and deposition techniques for making a flat single V butt weld in 12 mm thick material by (*a*) gas-shielded tungsten-arc welding and (*b*) gas-shielded metal-arc welding.

Other welding processes

1 (*a*) Explain *four* principles involved in the production of a weld.
   (*b*) State *four* variables which influence the production of friction welds.

2 The electroslag process is used for a wide range of welded work.
   (*a*) Outline the principles of this process.
   (*b*) Sketch a sectional view of the weld area during welding showing all the essential parts.
   (*c*) Explain how the joint may be set up to retain its shape and minimize transverse shrinkage.
   (*d*) State *three* reasons why run-on and run-off plates are required.
   (*e*) Describe a suitable method of testing the weld metal to assess its toughness.
   (*f*) Describe a heat treatment process that can be used to improve the toughness of the completed welded joint.

3 (*a*) Explain how heat is produced in the resistance spot welding process.

(*b*) The figure shows a time, pressure, current diagram which illustrates the sequence of operations for the formation of a resistance spot weld.

(1) Calculate the percentage of the total time during which the current flows to form the weld.

(2) Calculate the total heat energy generated in joules using the formula $J = I^2Rt$, where

I = current in amperes,
R = 0.001 ohm resistance,
t = time in seconds,
J = heat energy.

4 (*a*) Explain *four* principles involved in the production of a friction weld.

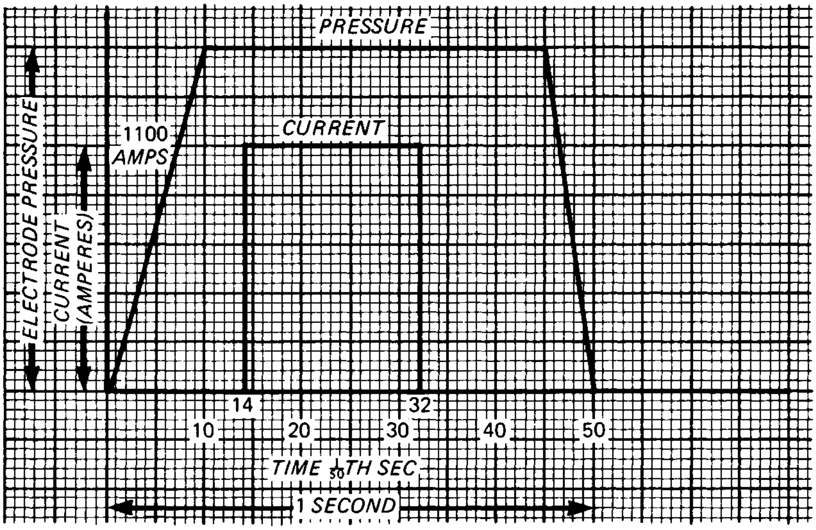
(*b*) State *four* variables which influence the production of friction welds.

5 For each of three of the following give a description of (1) the principles of operation, (2) a typical application:

(*a*) submerged arc welding.
(*b*) electric resistance spot welding,
(*c*) electroslag welding,
(*d*) arc stud welding.

6 With the aid of sketches show how resistance projection welding differs from resistance spot welding.

Question 3



7 Describe briefly the principles of operation, and give *one* suitable industrial application, for *three* of the following welding processes:
  (*a*) electroslag,
  (*b*) electric resistance flash butt,
  (*c*) electron beam,
  (*d*) friction.

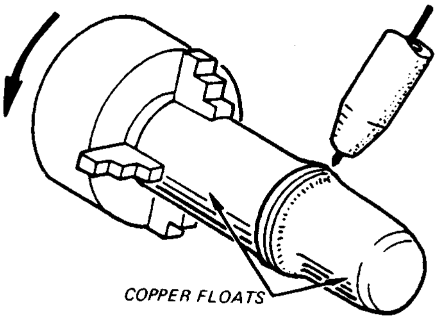
8 The figure shows a fixture arrangement for the automatic arc welding of copper floats using the gas-shielded tungsten-arc process.
  (*a*) State the influence the thermal conductivity of the metal would have on weld penetration.
  (*b*) State *three* factors other than thermal conductivity which would influence weld profile.

9 (*a*) List the following welding processes in their order of usefulness for welding steel components 50 mm thick, in the vertical position:
    (1) arc welding with coated electrodes,
    (2) electron beam welding,
    (3) electroslag welding,
    (4) laser beam welding.
  (*b*) Give a brief outline of friction welding.

10 (*a*) Explain why a flux is not required for resistance spot welding.
  (*b*) Give *three* possible causes of defective resistance spot welds.

11 The submerged arc welding process is used for a wide range of welded work.
  (*a*) Outline the principles of this process.
  (*b*) Explain why run-on and run-off plates are used.
  (*c*) State the purpose of vacuum recovery.

Question 8



(*d*) State *four* precautions to be taken in order to avoid porosity of the welded joint.

(*e*) State *four* advantages this process has over the manual metal-arc process.

Cutting processes

1 (*a*) State *two* methods used for gas cutting bevels on plate edges in preparation for welding.

(*b*) Describe, with the aid of a sectional sketch indicating the gas paths, the operation of an oxy-fuel gas cutting blowpipe.

2 (*a*) Make labelled sketches to show the essential difference between the nozzle assemblies used with

(1) acetylene,
(2) propane,

for the oxy-fuel gas cutting of low-carbon steel.

(*b*) After manual oxy-fuel gas cutting 50 mm thick low-carbon steel, it is required to cut 6 mm thick low-carbon steel plate. State the adjustment which will need to be made for this operation to be efficiently carried out.

3 Explain the action which produces the severance of the metal when oxy-fuel gas cutting low-carbon steel and state the difference between the basic principles of gas cutting and flame gouging.

4 (*a*) Give three operations which are essential during the assembly of a high-pressure oxy-acetylene cutting plant to ensure safe and effective service.

(*b*) Show by means of labelled sketches the angles of slope and tilt of the electrode when making a straight cut in 8 mm thick low-carbon steel plate in the flat position by the air-arc process.

5 (*a*) What is meant by 'oxygen lance cutting'? Give *two* examples of its use.

(*b*) Describe with the aid of sketches the technique required when cutting low-carbon steel-plate in the flat position by the use of each of the following arc cutting processes:

(1) air-arc,
(2) oxygen arc.

6 Unsuitable variations during oxy-fuel gas cutting of steel may lead to faults along the cut face. Show, by means of labelled sketches of the cut face, the faults which would be caused by either:

(1) the speed of travel being too fast, or

(2) the nozzle being too high above the work surface.

7 (*a*) Explain how the correct size of cutting nozzle to be used in the oxy-fuel gas cutting process should be determined.

(*b*) Discuss the influence on the oxy-fuel gas cutting operation of any two alloying elements which may be present in the steel.

(*c*) Describe how cast iron can be cut by the oxy-fuel gas cutting process.

8 (*a*) Explain the action which causes the severance of the metal when using the oxy-fuel gas cutting process for the cutting of austenitic stainless steel.

(*b*) What is meant by stack cutting? List *two* advantages of the use of stack cutting.

9 (*a*) Give *two* advantages in *each* case which may be obtained when oxy-fuel gas cutting:

(1) manually,
(2) by machine.

(*b*) Describe, with the aid of a sketch, a suitable arc cutting process for the cutting of ferrous and non-ferrous metals.

10 (*a*) What is arc plasma?
By means of a simple labelled outline diagram, show one method of using arc plasma for cutting purposes.

(*b*) Explain the differences between

(1) a single port nozzle,
(2) a multi-port nozzle as used with plasma arc cutting.

(*c*) Show, by means of diagrams, the finished cut that is produced by each of these nozzles after cutting 4.5 mm thick austenitic stainless steel.

11 The following thermal cutting equipment is available for use:
oxy-acetylene manual cutting equipment,
arc plasma profile cutting machine,
oxy-acetylene cutting equipment complete with lance,
oxy-acetylene cutting equipment complete with dispenser unit.
From the cutting equipment available select, with reasons, which cutting process should be used for cutting each of the following materials to the shape or form specified. Do not use the same process for cutting both materials.

(1) 200 mm diameter discs to be cut from 20 mm thick austenitic stainless steel plate.
(2) The removal of excess material from a newly cast grey iron casting.

(3) Outline the principles of the thermal cutting process used.
(4) State *two* aspects of safety that are particularly appropriate to each process used.

12 State why the arc plasma process would be used in preference to oxygen and fuel gas cutting of austenitic stainless steel.

13 (*a*) Why is it necessary to pre-heat medium- and high-carbon steels before cutting by the oxy-fuel gas cutting process?
(*b*) State the factors that prevent the use of natural gas as an oxy-fuel cutting gas.

14 (*a*) Discuss the health hazards that can be encountered when cutting galvanized steel sheet.
(*b*) State the safety precautions that should be adopted to ensure that workshop personnel can be protected against these hazards.

15 (*a*) Describe two suitable thermal cutting processes which could be used to cut 1 metre diameter blanks from 12 mm thick austenitic steel plate.
(*b*) Compare the *two* methods selected in (*a*) with regard to:
(1) cost,
(2) speed of cutting,
(3) distortion,
(4) treatment after cutting.

16 (*a*) List the following cutting process in sequence with regard to best quality of cut face for the thermal cutting of austenitic stainless steel 38 mm thick in the flat position:
(1) oxygen-arc,
(2) air-arc,
(3) oxy-fuel-gas powder,
(4) arc-plasma.
(*b*) Explain, with the aid of a sketch, how the heat is produced for cutting by the plasma cutting process.

17 (*a*) Explain briefly the principles of *laser cutting*.
(*b*) List the advantages of laser cutting over conventional methods of cutting such as oxy-fuel gas and oxy-arc cutting.

Oxy-acetylene

1 (*a*) State *four* problems associated with the welding of copper.
(*b*) State what type of flame setting should be used and how it is attained.
(*c*) Describe in detail the welding procedure.

2 (*a*) Unsuitable variations during oxy-fuel gas cutting of steel may lead to faults along the cut face. Show, by means of labelled sketches of the cut face, the faults which would be caused by *either*
  (1) the speed of travel being too fast, *or*
  (2) the nozzle being too high above the work surface.
(*b*) State *two* methods which may be used for back gouging the root, ready for a sealing run, on the reverse side of welded butt joints in low-carbon steel.

3 Describe briefly the fundamental differences between the following: (*a*) the technique for the bronze welding of cast iron, and (*b*) the technique for the fusion of welding of cast iron.

4 (*a*) Describe, with the aid of sketches, the all-position rightward technique to be used when making a butt joint in low-carbon steel pipe 100 mm diameter by 5 mm wall thickness, the pipe axis to be in the fixed vertical position throughout.
(*b*) Compare the respective advantages and limitations of the leftward and the rightward techniques when used for the butt welding of low-carbon steel plate, 5 mm thick, in the flat position.

5 (*a*) Describe briefly, with the aid of a sectional sketch and indicating the gas paths, the mode of operation of *either*
  (1) a non-injector type welding blowpipe, *or*
  (2) a single-stage gas pressure regulator.
(*b*) What precautions are necessary during the assembly of a high-pressure oxy-acetylene cutting plant in order to ensure safe and effective operation?
(*c*) Explain why the specified discharge rate of a dissolved acetylene cylinder must not be exceeded when in use.

6 (*a*) Describe in detail, with the aid of sectional sketches, *four* defects which may occur during the oxy-acetylene welding of low-carbon steel, stating in *each* case its cause and explaining how it may be avoided.

7 Describe the technique necessary to form a tee-fillet joint in 1.6 mm commercially pure aluminium sheet by the flame brazing process.

State the type of filler wire and flame setting needed. You may use a sketch to illustrate your answer.

8 (*a*) Name three impurities found in acetylene gas immediately after generation.
(*b*) Explain how acetylene gas may be tested for purity.

9 (*a*) Summarize the problems encountered in the oxy-acetylene repair welding of each of the following cast materials: (1) zinc base die cast alloy, (2) magnesium alloy.
(*b*) Describe the preparation, welding technique and post-weld treatment necessary for each.

10 (*a*) When would a carburizing flame be used for joining metals?
(*b*) What purpose is served by the use of such a flame adjustment?

11 Describe, with the aid of a simple outline sketch, one example of a repair welding operation where *studding* could be employed with advantage.
(*a*) Name two advantages of using a high silicon content in cast iron, or in cast iron filler rods for welding purposes.
(*b*) Give the approximate percentage of silicon contained in a 'super-silicon' cast iron filler rod.

12 (*a*) What is meant by the term 'hard-facing'?
(*b*) Name two types of filler rod that may be used for hard-facing operations.

13 (*a*) Name the fuel gas generally used for underwater flame cutting operations.
(*b*) State one good reason why this gas is used.

14 (*a*) Explain, in detail, four safety measures that should be taken before carrying out welding repairs on a 150 litre (30 gallon) low-carbon steel petrol tank.
(*b*) Describe the hazards encountered when welding galvanized metals. State the precautions to be taken in the interests of health and safety.

15 A 6 mm thick magnesium alloy casting is cracked for a length of 150 mm and is to be repaired by oxy-acetylene welding.
(*a*) Outline the preparation which may be required before welding.
(*b*) Give *two* methods of indicating the correct pre-heat temperature.
(*c*) Describe a suitable method of stress relieving after welding.
(*d*) Explain how the flux residue should be removed.

16 A cobalt-based, hard-facing alloy is required to be deposited on to a low-carbon steel component.
(*a*) State how the component could be prepared.
(*b*) Name the type of flame setting required for a single layer deposit and give *two* reasons for your choice.

(*c*) State *two* precautions to be taken to avoid defects.

17 What is the included angle of preparation necessary for single-vee butt welded joints to be made by the oxy-acetylene process using (1) the leftward technique, and (2) the rightward technique?

18 (*a*) What is meant by 'all-position rightward welding'?
(*b*) Give two important advantages which may be obtained by the use of this technique for the welding of pipe joints.

19 (*a*) Explain briefly how (1) carburizing and (2) oxidizing oxy-acetylene flame settings are obtained.
(*b*) Give one important application of each flame setting.

20 What is the purpose of (*a*) portable cylinder couplers in oxy-acetylene welding, (*b*) a brushless d.c. generator for metal-arc welding?

21 (*a*) Make a labelled section-sketch to show the arrangement of the nozzle assembly used for progressive flame gouging.
(*b*) State two methods used for gas-cutting bevels on plate edges in preparation for welding.

22 Name one possible cause of each of the following, when oxy-acetylene welding butt joints in mild steel: (*a*) excessive penetration, (*b*) incomplete penetration, (*c*) adhesion.

23 (*a*) What is the difference between a backfire and a flashback?
(*b*) Name five possible causes of backfiring when using a gas welding blow-pipe. In each case explain how backfiring could have been avoided.
(*c*) State two difficulties which may be experienced in the efficient operation of a gas pressure regulator.
(*d*) State the purpose of each part of the high-pressure oxy-acetylene welding system.

24 Sketch the joint preparation and set-up, and state the nozzle size (in cubic feet or litres per hour) and filler rod size to be used, for making: (1) butt welds in the vertical position in each of the following thickness of mild steel: 3.2 mm ($\frac{1}{8}$ in.) and 5 mm ($\frac{3}{16}$ in.); (2) a tee fillet-weld in the horizontal–vertical position in 5 mm ($\frac{3}{16}$ in.) thick mild steel plate.
Describe in detail, with the aid of sketches, the fusion welding of a butt joint in cast iron 10 mm ($\frac{3}{8}$ in.) thick.

25 Explain what is meant by gas velocity and outline how this is controlled in welding practice.

26 Describe, with the aid of a sectional sketch indicating the gas paths, the operation of an oxy-fuel gas cutting blowpipe.

27 (*a*) Sketch the joint preparation and set-up and state the nozzle and filler rod sizes to be used for making:
   (1) a butt weld in the vertical position in 3 mm thick low-carbon steel,
   (2) a close-square tee fillet weld in the horizontal–vertical position in 5 mm thick low-carbon steel,
   (3) a fusion welded butt joint in the flat position in 10 mm thick cast iron.
(*b*) Describe in detail, with the aid of sketches, the procedure and the technique required for making any *one* of the joints in part (*a*) above.

28 Outline one method which may be used during the oxy-acetylene welding of vertical butt joints, in 4 mm thick low-carbon steel, to ensure freedom from weld defects when
(*a*) starting the weld at the beginning of the joint,
(*b*) restarting the weld at a stop-point along the joint.

29 State *two* safety precautions which should be taken for *each* of the following:
(*a*) storage or use of dissolved acetylene cylinders,
(*b*) using gas pressure regulators,
(*c*) oxy-acetylene cutting operations in a confined space,
(*d*) using non-injector type gas welding blowpipes.

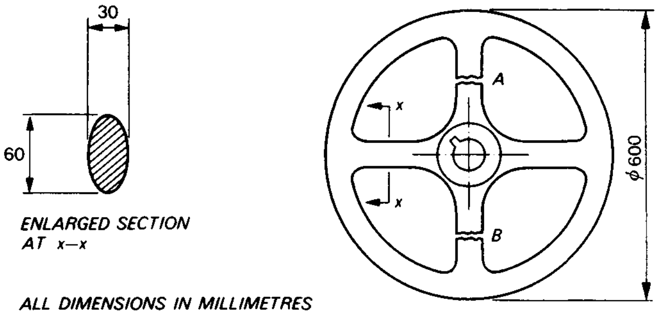
30 (*a*) Explain the action which produces the severance of the metal when oxy-fuel gas cutting low-carbon steel and state the difference between the basic principles of gas cutting and flame gouging.
(*b*) Describe, with the aid of a sectional sketch indicating the gas paths, the operation of an oxy-fuel gas cutting blowpipe.

31 Explain what is meant by capillary attraction and describe how this affects the making of certain brazed joints.

32 The figure shows a cast iron wheel with two broken spokes. With the aid of a sketch, indicate how partial pre-heating may be used to minimize the risk of cracking.

33 (*a*) Describe with the aid of sketches the technique for making a lap fillet weld in the horizontal–vertical position by the oxy-acetylene process.
(*b*) Compare the respective advantages and limitations of the leftward and the Lindewelding techniques when butt welding mild steel pipes.

Question 33



Multiple choice

Note: The following are examples of the multiple choice type of question but may not be representative of the entire scope of the examination either in content or difficulty.

1 Because of the possibility of explosions, acetylene line fittings should *not* be made from
(*a*) steel
(*b*) copper
(*c*) aluminium
(*d*) cast iron.

2 One reason why low-carbon steel may be successfully welded by oxy-acetylene without the use of a flux, is that the oxide
(*a*) is under the surface
(*b*) has a higher melting point than the parent metal
(*c*) has a lower melting point than the parent metal
(*d*) melts at the same temperature as the parent metal.

3 An undesirable property of an aluminium flux residue is that it
  (*a*) is corrosive
  (*b*) obstructs the vision of the molten pool
  (*c*) decreases fluidity
  (*d*) requires great heat to melt it.

4 When a low-alloy steel has a hard and brittle structure it may be rendered soft and malleable by
  (*a*) recrystallization
  (*b*) cold working
  (*c*) lowering its temperature
  (*d*) hot quenching.

5 What happens to the mechanical properties of steel if the carbon content is increased to 0.5%?
  (*a*) The material becomes softer.
  (*b*) Malleability is increased.
  (*c*) The tensile strength is increased.
  (*d*) Ductility is increased.

6 The main reason for pre-heating medium- and high-carbon steels before cutting by the oxy-fuel gas technique is to
  (*a*) improve the quality of cut
  (*b*) increase the cutting speed
  (*c*) refine the grain structure
  (*d*) prevent hardening and cracking.

7 Which one of the following factors restricts the use of town gas as an oxy-fuel cutting gas?
  (*a*) Its low calorific value.
  (*b*) Its tendency to cause rapid melting.
  (*c*) Its unsuitability for cutting plates less than 12 mm thick.
  (*d*) Its relatively high cost.

8 A suitable filler wire for brazing pure aluminium would consist of:
  (*a*) aluminium bronze
  (*b*) aluminium alloy containing 10/13% silicon
  (*c*) aluminium alloy containing 5% magnesium
  (*d*) pure aluminium.

9 Columnar growth takes place when a metal is
  (*a*) cold
  (*b*) losing heat
  (*c*) being heated
  (*d*) being rolled.

10 Difficulty may be encountered when welding aluminium because
  (*a*) the weld metal expands during solidification

(*b*) its coefficient of expansion is low compared to steel
(*c*) no colour change takes place to indicate its melting points
(*d*) its thermal conductivity is low compared to steel.

11 One purpose of a microscopic examination of a weld is to establish the
(*a*) strength of the weld
(*b*) number of alloying elements
(*c*) grain size
(*d*) number of runs used.

12 Which one of the following components is employed to control amperage in an a.c. arc-welding circuit?
(*a*) rheostat
(*b*) choke
(*c*) voltmeter
(*d*) resistor.

13 When carrying out welds in low-carbon steel, using the carbon dioxide welding process, one purpose of the inductance control is to reduce
(*a*) porosity
(*b*) penetration
(*c*) undercut
(*d*) spatter.

14 One purpose of a reactor (choke) when manual metal arc welding is to
(*a*) change alternating current to direct current
(*b*) allow the correct amperage to be selected
(*c*) allow the desired arc voltage to be selected
(*d*) enable the correct polarity to be chosen.

15 Which shielding gas is generally recommended when butt-welding 6 mm nickel alloy sheet by the metal-arc gas-shielded process?
(*a*) Argon
(*b*) CO_2
(*c*) Hydrogen
(*d*) Nitrogen.

16 When TIG welding using a.c. output, which one of the following is essential in the circuit to stabilize the arc?
(*a*) A surge injector
(*b*) An open circuit voltage of 100 volts
(*c*) A flow meter
(*d*) An amperage regulator.

17 In manual metal-arc welding the flux coating to give deep penetration characteristics would contain

(*a*) iron oxide
(*b*) manganese
(*c*) cellulose
(*d*) calcium carbonate.

18 Which element is used as a deoxidant in copper filler rods?

(*a*) Aluminium
(*b*) Tin
(*c*) Sulphur
(*d*) Phosphorus.

19 An oxygen cylinder regulator being used in a flame-cutting supply may freeze up if the

(*a*) gas withdrawal rate is exceeded
(*b*) cylinder content is too low
(*c*) cylinder is on its side
(*d*) needle valve on the regulator is not fully open.

20 To test a component part for a vibrational loading, a suitable mechanical test would be

(*a*) impact
(*b*) tensile
(*c*) compressive
(*d*) fatigue.

21 The principal advantage of arc-on-gas welding is that it

(*a*) allows controlled penetration of initial bead
(*b*) requires less operator skill
(*c*) entirely eliminates distortion
(*d*) improves surface finish.

22 One reason why a grey cast iron casting should be slowly cooled after welding is to keep it

(*a*) soft
(*b*) spheroidal
(*c*) hard
(*d*) brittle.

23 An iron casting has a crack in it. Before oxy-acetylene fusion welding it may be necessary to drill the ends of the crack. One reason for this is to

(*a*) balance out any shrinkage stresses
(*b*) stop the crack from spreading
(*c*) prevent the ends of the crack from being carburized
(*d*) prevent grain growth.

24 Which one of the following metals may require the studding

techniques to be used when being repaired by manual metal arc welding?

(*a*) Low-carbon steel
(*b*) Aluminium
(*c*) Nickel
(*d*) Cast iron.

25 During the deposition of a manual metal-arc electrode, a certain percentage of the core wire is lost. This is due to

(*a*) voltage drop across the arc
(*b*) short arc length
(*c*) spatter
(*d*) excessive build-up.

26 Which one of the following can be welded by d.c. using the tungsten arc gas-shielded process?

(*a*) Copper
(*b*) Commercial pure aluminium
(*c*) Silicon–aluminium
(*d*) Magnesium alloys.

27 Backing bars for manual metal-arc welding of low-carbon steel should be made from

(*a*) copper
(*b*) low-carbon steel
(*c*) tool steel
(*d*) cast iron.

28 Peening may be carried out when manual metal-arc welding cast iron in order to

(*a*) reduce the effects of contraction
(*b*) make the bond more firmly adhering
(*c*) refine the grain structure
(*d*) speed up the welding.

29 The fillet welds on the support brackets in the figure should have 5 mm leg length with 50 mm intermittent welds as shown. The symbol at *A* to communicate this information should be

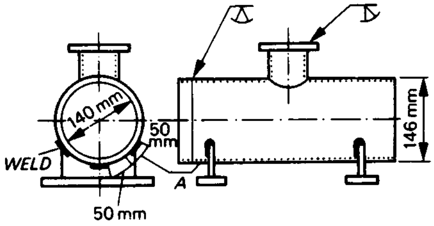
(a)

(b)

(c)

(d)

30 What is the volume of deposited metal in a fillet weld indicated by the symbol in the figure neglecting reinforcement?
(*a*) 14000 mm^3
(*b*) 14900 mm^3
(*c*) 15000 mm^3
(*d*) 15 100 mm^3.



Question 29. The figure shows a component fabricated from stabilized austenitic stainless steel sheet 3 mm thick.

Welding engineering craft studies

All dimensions are in millimetres

1 Spot welds are to be made by the tungsten arc gas-shielded welding process.
(*a*) Make a sectional sketch through one of these spot welds.

(*b*) State *one* advantage that this process has over the resistance spot welding process for making this type of weld.

(*c*) Name the additional equipment that would be necessary for making the spot welds using standard tungsten arc gas-shielded welding equipment.

2 (*a*) How is the size of a fillet weld with normal penetration determined in accordance to BS 499 in
  (1) a convex fillet weld,
  (2) a concave fillet weld?

(*b*) Make a sectional sketch of a mitre fillet weld.

3 State *five* factors that would influence the pre-heating temperature to be used for a welded steel fabrication.

4 (*a*) Give *two* reasons why hydrogen-controlled electrodes are preferred for manual metal-arc welding restrained joints in low-alloy steel.

(*b*) Explain the influence of the cellulose in the coating of an electrode on
  (1) voltage,
  (2) penetration.

5 A circular low-carbon steel plate of 750 mm in diameter and 10 mm thick has to be fitted and welded into a deck plate.

(*a*) State why hot cracking is likely to occur in this particular type of assembly.

(*b*) Outline *either* a suitable weld sequence *or* a change in the form of the plate insert that could be used to avoid the occurrence of hot cracking.

6 A worn press die has to be built up using the oxy-acetylene flame powder spraying process.

(*a*) From the table select the powder to be used for this repair.

(*b*) List *three* advantages that powder spraying has over arc welding for this type of repair.

(*c*) Name the type of flame setting to be used.

Powder no.	Resistance to:		
	Abrasion	Impact	Machinability
1	Fair	Excellent	Very good
2	Very good	Excellent	Very good
3	Excellent	Poor	Grind only

7 From the information given below, list in the correct order the welding sequence that should be carried out when friction welding two 20 mm diameter low-carbon steel bars.
- (*a*) Place parts lightly in contact.
- (*b*) Load machine.
- (*c*) Apply axial force.
- (*d*) Apply upset force.
- (*e*) Rotate chuck and close gap.
- (*f*) Release upset force.
- (*g*) Arrest chuck movement.
- (*h*) Remove specimen.

8 Steel cylindrical tanks 5 m long and rolled to 2 m internal diameter from 50 mm thick low-carbon steel plate are to be welded, using the electroslag welding process for the longitudinal seams.
- (*a*) With the aid of a sketch outline how the weld area is protected from atmospheric contamination.
- (*b*) (1) State *three* advantages that the electroslag welding process has over arc welding processes for welding process for the longitudinal seams.
  - (2) Give *two* limitations of the electroslag welding process.
- (*c*) (1) What is the purpose of run-on and run-off plates when electroslag welding?
  - (2) After electroslag welding has commenced small additions of flux must continue to be added to the weld pool. Why is this?
- (*d*) If it was considered that the cylinder would be working under conditions that may cause stress corrosion cracking:
  - (1) State what is meant by the term stress corrosion cracking,
  - (2) State *two* precautions that could be taken to reduce the occurrence of failure from this form of attack.

9 The figure shows a low-carbon steel nut to be resistance projection welded to 2 mm thick low-carbon steel sheet.
- (*a*) Explain the principles involved in making this welded connection using the resistance welding process.
- (*b*) Make a sectional sketch through *A–A* of the welded assembly shown in the figure.
- (*c*) State *two* advantages of resistance welding over manual metal-arc welding for making this welded connection.
- (*d*) List *three* defects that may be found when resistance *spot*

welding, and in each case state the probable cause of the defect.

10 As part of a welding sequence, stiffeners require to be welded to the aluminium alloy plate shown in the figure.

(*a*) Select a suitable process for welding the stiffeners.

(*b*) Sketch and label the essential components of the welding circuit for the process selected.

(*c*) Using a graph to illustrate your answer, give a brief outline of the output characteristics of the power source needed for the process used.

(*d*) What information is indicated by the weld symbol shown in the drawing?

11 Alloy steel of the following % composition has to be manual metal-arc welded.

Carbon (C)	Chromium (Cr)	Molybdenum (Mo)	Manganese (Mn)	Silicon (Si)	Nickel (Ni)	Vanadium (V)
0.16	1.5	0.5	0.8	0.4	0.0	0.0

Remainder: iron with acceptable limits of impurities.

(*a*) State *three* advantages of using alloying elements in steel.

(*b*) (1) Using the carbon equivalent formula given below determine the carbon equivalent of the alloy steel outlined above.

Carbon equivalent (%) =

$$C\% + \frac{Mn\%}{20} + \frac{Ni\%}{15} + \frac{Cr\% + Mo\% + V\%}{10}$$

(2) Indicate how the information produced may be used to determine the welding procedure used.

(*c*) Explain why pre-heating this alloy may reduce the occurrence of underbead cracking.

(*d*) Welds made on low-alloy steels are generally heat treated by normalizing.

(1) What is meant by normalizing?

(2) State *three* advantages produced by normalizing welded fabrications.

12 State *five* factors that will influence dilution during fusion welding.

13 (*a*) Give *three* reasons for pre-heating air-hardenable steels before or during oxy-fuel gas cutting.

(*b*) Give the main constituents in an air-hardenable steel.

14 Briefly explain how a friction weld is produced.

15 (*a*) State *three* advantages of using fully automatic welding processes in preference to manual welding processes.

(*b*) Under what circumstances may manual welding be preferred to fully automatic welding?

16 (*a*) Explain how heat is produced during cutting when using the oxygen lance.

(*b*) State *two* safety precautions that should be taken when using the oxygen lance for cutting.

17 List *five* problems which may be encountered when fusion welding aluminium.

18 Explain briefly why single-pass welds made by the arc plasma process may have the form shown in the macrograph in the figure.

19 One thousand circular containers as shown in the figure have been fabricated from low-carbon steel by using the metal-arc gas-shielded welding process with carbon dioxide as shielding gas.

   (*a*) Name the main type of stress, in *each* case, that weld *A* and *B* would be subjected to during hydraulic testing.

   (*b*) During testing some welds were found to contain porosity. State *three* probable causes of this defect.

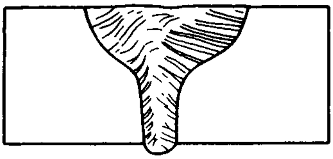
20 (*a*) The figure shows a time and current graph making an electric resistance spot weld. The following two parts of this question refer to this diagram.

   (1) Calculate the weld time as a percentage of the welding cycle.

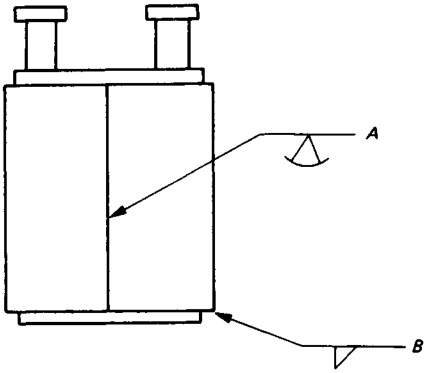
   (2) Explain why it is generally necessary for the forging time to be longer than the squeeze time.

   (*b*) A resistance spot welding machine was set up for welding low-carbon steel. If austenitic stainless steel of the same

Question 18



Question 19



thickness is to be welded, what alterations would require to be made to

(1) the welding current,

(2) the welding time?

Explain why these alterations are necessary.

(*c*) Spot welding of sheet metal may also be carried out by fusion welding.

(1) Select a fusion welding process and describe how a spot weld is made using this process.

(2) What additional equipment would be necessary for making spot welds using standard equipment?

21 The figure shows a low-alloy steel rotary shear blade, used for trimming steel plate. The cutting edge has become worn due to severe abrasion during service and is to be repaired by using the manual metal-arc welding process.

(*a*) The general composition of three electrodes is shown below. Select the most suitable electrode for use in the building up of the cutting edge, and give a reason for your selection.

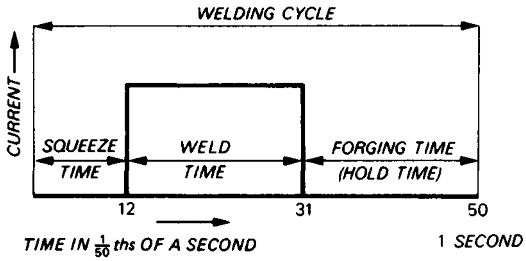
(1) Austenitic stainless steel.

(2) Medium-carbon low-alloy steel.

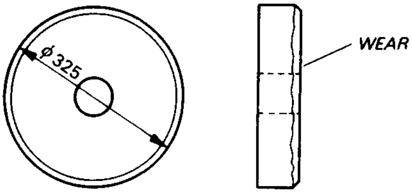
(3) Pure nickel.

(*b*) Outline the welding procedure that should be used to carry out this repair.

Question 20



Question 21



(*c*) Explain the influence that the dilution of the weld metal by the parent metal would have on the weld's mechanical properties.

(*d*) Under what circumstances would the oxy-acetylene welding process be preferred to arc-welding processes for hard surfacing?

22 The figure shows a low-carbon steel shaft to be fabricated by welding using the submerged arc welding process.

(*a*) With the aid of a sketch, explain how the weld area is protected from atmospheric contamination.

(*b*) State *three* advantages of using a backing strip for this joint.

(*c*) Sketch in detail the weld preparation that would be used for the butt weld shown at *A*.

(*d*) Why is the filler used in submerged arc welding copper coated?

(*e*) When submerged arc welding, explain why it is an advantage to use a multipower source which has one electrode using alternating current and the other direct current.

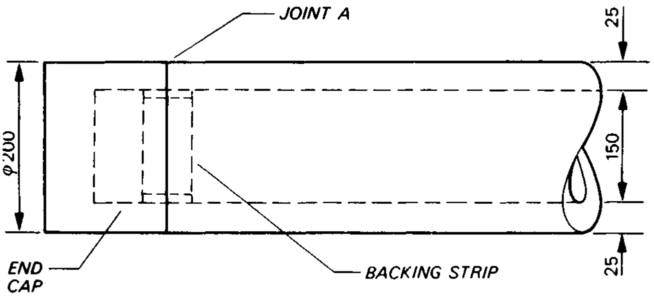
23 50,000 shear connectors are to be welded to the low-carbon steel box girder shown in the figure, using the drawn arc stud welding process.

(*a*) In what respect does the purpose-built power source used for this type of equipment differ from the power source used for metal-arc welding?

(*b*) Sketch in section, and label the main parts of, a ceramic ferrule used for stud welding.

(*c*) If the shear connectors are to be positioned at 100 mm centres, explain how this could be best achieved.

Question 22



ALL DIMENSIONS IN mm

(*d*) (1) Describe a method of testing the stud welds.
(2) Welds having the section shown in *d*(2) below failed during testing due to the defects shown. State *four* possible causes of these defects.

24 Power souces used for electron beam welding may be rated as 30 kV.
(*a*) Explain the term 30 kV.
(*b*) Give *two* reasons why electron beam welding is generally carried out in a vacuum.

25 (*a*) State *four* of the variables involved in the production of friction welds.
(*b*) State the range or temperature necessary for the production of friction welds in low-carbon steel.

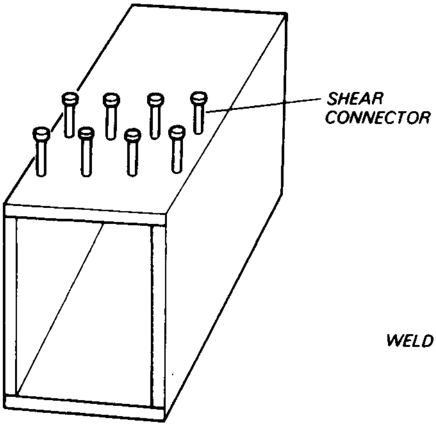
26 Sketch in section, and label the parts of, the head of an arc plasma torch for welding.

27 (*a*) State *three* advantages of introducing iron powder into the flame when oxy-acetylene powder cutting.
(*b*) State *two* hazards that the operator should guard against when oxy-acetylene powder cutting.

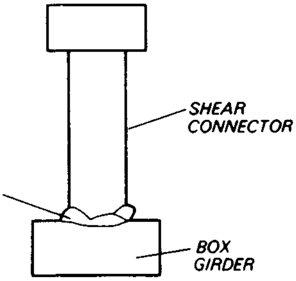
28 Low-carbon steel plate 25 mm thick has to be surfaced by the submerged arc welding process using stabilized austenitic stainless steel filler. List *five* variables that would influence the degree of dilution found in the weld.

29 Explain why it is recommended that materials containing sulphur should be removed from the weld area before welding nickel and nickel alloys.

Question 23



Question 23. (*d*) (2)



30 State *five* factors that would need to be considered before deciding the pre-heating temperature to be used on low-alloy steel plate.

31 (*a*) With the aid of a graph, explain why a constant potential power source is often preferred for automatic arc welding processes.

(*b*) List *four* variables, under the control of the welder, that can influence weld quality when using the submerged arc welding process.

(*c*) Explain why the quality of submerged arc welds made in low-alloy steels is particularly high compared with the quality of welds made by other arc welding processes.

(*d*) Inspection authorities may specify that welds made by the submerged arc welding process should be heat treated. Outline a suitable heat treatment.

32 The grey cast iron angle plate shown in the figure has to be repaired by manual metal-arc welding and then machined flush. Rutile-covered low-carbon steel and nickel alloy electrodes are available for making the weld.

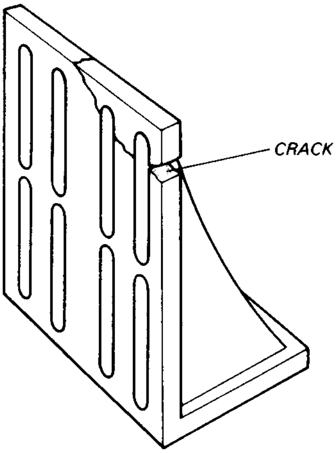
(*a*) Select the most suitable electrode to carry out this repair.

(*b*) State *two* advantages and *one* disadvantage of the electrode selected.

33 The aluminium–magnesium alloy components shown in the figure are to be welded using the metal-arc gas-shielded welding process.

(*a*) Explain why an argon/carbon dioxide gas mixture would be unsuitable as the gas shield to be used for welding the components.

Question 32



(*b*) State *three* factors that would influence the weld profile.

(*c*) Explain why the oxy-acetylene fusion welding process would be unsuitable for welding the components.

(*d*) Outline the influence that welding would have on the metal's mechanical properties and grain structure.

(*e*) If 1000 components are to be fabricated, calculate the total length of welding carried out to complete the contract. Each joint is to be made by means of a single-run weld deposit.

34 (*a*) Calculate the volume of metal deposited in the welded joint shown in the figure if the length of the joint is 10 m, and the total weld reinforcement is taken as one quarter of the total volume of the joint gap.

(*b*) Outline the influence of *each* of the following factors on the cost of welded fabrication:

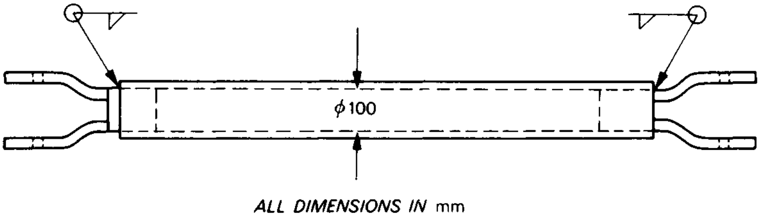
(1) current density,

(2) joint set-up.

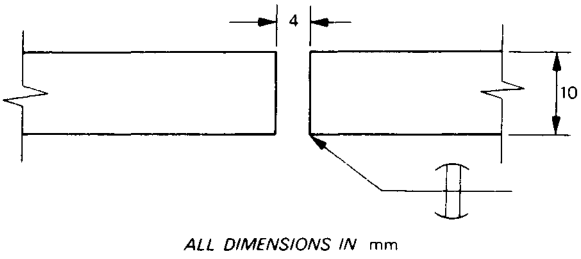
(*c*) Outline how *four* factors in the welding procedure can influence welding costs.

(*d*) Sketch an example of a non-load bearing fillet weld, indicating by an arrow the direction of the applied load on the component when in service.

Question 33



Question 34



35 A fabricated tank is to be manufactured from stabilized austenitic stainless steel. The weld preparation and holes are to be thermally cut using the arc plasma process.

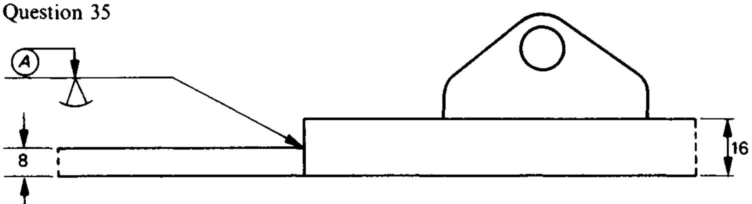
- (*a*) Explain why the arc plasma process would be used in preference to oxygen and fuel gas for cutting this material.
- (*b*) Sketch in detail the design of the welded butt joint shown at *A* in the figure.
- (*c*) State *two* problems which may be encountered during the arc welding of this joint.
- (*d*) Explain why the depth of penetration would be greater in welds made in austenitic stainless steel, compared with similar welds made in low-carbon steel, assuming the energy input to be the same.
- (*e*) Explain, with the use of a graph, why a drooping characteristic power source should be used when manual metal-arc welding, rather than a constant potential power source.

36 Component parts for an oil rig, having the form shown in the figure, are to be fabricated and joined by welding.

- (*a*) Calculate the carbon equivalent of the steel given the following:

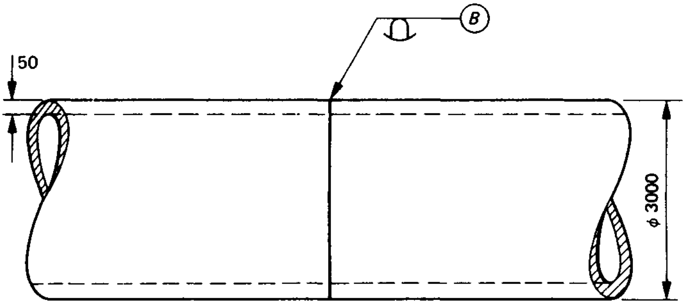
  Material composition: Carbon, 0.22%; Silicon, 0.5%;

Question 35



ALL DIMENSIONS IN mm

Question 36



ALL DIMENSIONS IN mm

Manganese, 1.5%; Niobium, 0.1%; Vanadium, 0.1%; Sulphur, 0.05%; Phosphorus, 0.05%; remainder iron.

Carbon equivalent =

$$C\% + \frac{Mn\%}{6} + \frac{Cr\% + Mo\% + V\%}{5} + \frac{Ni\% + Cu\%}{15}$$

(*b*) Sketch in detail the butt joint preparation shown at *B*.

(*c*) Outline a welding procedure that could be used to make the joint.

(*d*) Since this component will be subjected to fatigue conditions during service, state *three* precautions which should be taken when welding has been completed.

37 (*a*) The figure shows a cruciform welded joint. Using the formula $l = 1.4\, t$ calculate the throat size (t) of a fillet weld if the leg length (l) is 21 mm.

(*b*) Show by means of a labelled sectional sketch a fillet weld leg length of 21 mm.

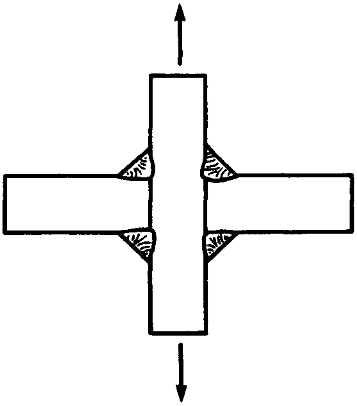
(*c*) A load is applied in the direction of the arrows indicated in the figure. State whether the welds are load bearing or non-load bearing.

(*d*) The material shown in the figure has a relatively high carbon equivalent and pre-heating temperatures have not been maintained during welding so that underbead cracking has resulted. Explain how the underbead cracking would take place.

(*e*) What is meant by the term 'fatigue fracture'?

(*f*) State *four* factors under the control of the welder which may adversely affect the fatigue life of a single-vee butt-welded joint.

Question 37



(*g*) State *three* precautions that could be taken to reduce the occurrence of a brittle fracture failure in a welded joint.

38 The figure shows an austenitic stainless steel hopper which has to be fabricated from 5 mm thick sheet.

(*a*) State *four* methods which may be used to ensure a low heat input procedure for arc welding the hopper.

(*b*) (1) State the value of the included angle *X* for the joint shown at *B*.

(2) State *two* reasons why the included angle *X* should be increased if welding has to be carried out.

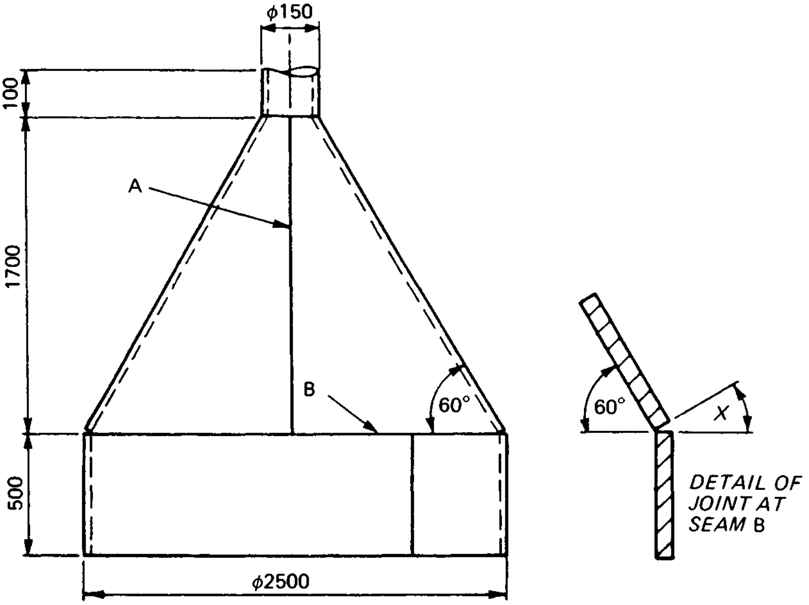
(*c*) Four different welding procedures could be used for making the butt-welded joints shown at *A* and *B*. State *one* advantage and *one* disadvantage for *each* of the following welding procedures.

(1) Completely weld the joints using the tungsten arc gas-shielded process.

(2) Completely weld the joints using the gas-shielded metal-arc process.

(3) Weld the first run using the tungsten arc gas-shielded process and complete the weld using the manual metal-arc process.

Question 38



(4) Completely weld the joints using the manual metal-arc process.

(*d*) (1) Explain why distortion is likely to be a problem when welding this material.

(2) Describe a method that could be used to control the distortion when welding joint *A*.

39 The figure shows a fabrication which is to be made from 25 mm thick low-carbon steel using the gas-shielded metal-arc welding process with flux cored electrode wire.

(*a*) Give *three* reasons why flux cored electrode wire may be preferred for welding this fabrication in preference to solid wire.

(*b*) State *two* advantages of using a gas shield in addition to the flux cored electrode wire when using this process.

(*c*) A root crack was observed when welding the single bevel butt weld joint shown in (*b*). State *three* possible causes for its formation.

(*d*) State *three* factors which may cause porosity during welding, assuming the joint surfaces were clean before welding was carried out.

(*e*) Calculate the area of the side plate shown as *A* on (*a*).

40 (*a*) State *one* reason why

(1) some welding specifications permit a small amount of slag inclusion in a welded joint,

(2) it would not be realistic for a specification to state that a welded joint must be free from defects,

(3) welding specifications do not permit welded joints containing cracks to be accepted.

(*b*) Show, with the aid of a sketch, how the design size of a butt weld is measured.

41 (*a*) The figure shows butt and fillet joints which are to be joined by manual metal-arc welding. Explain why the welding specification may state that for the same heat energy input the butt-welded joint would not require to be pre-heated, although the fillet welded joint should be.

(*b*) The hardness of the gas cut edge shown in '*X*' in (*b*) was found to be unacceptably high. State *three* changes in the oxy-fuel gas cutting procedure that could have been taken to reduce the hardness value.

42 The figure shows a low-carbon steel oil storage tank which is to be fabricated from 18 mm thick low-carbon steel plate using the submerged arc welding process.

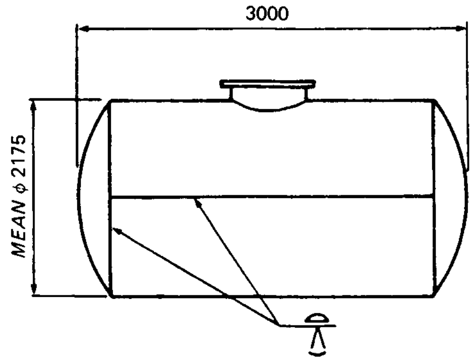
Question 42



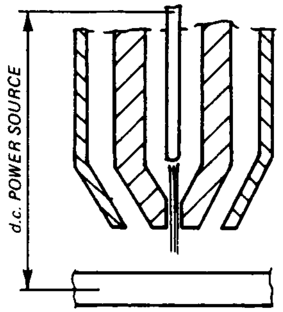
3000
MEAN ϕ 2175

(*a*) Calculate the length of plate required to be gas cut and rolled to form the cylindrical section of the tank.
(*b*) Explain why run-on and run-off plates are used when welding the longitudinal seam.
(*c*) Explain why welds made using the submerged arc welding process usually have a low level of defects.
(*d*) If the weld deposit was required to have good impact properties state whether it would be made with either a large number of runs or as few a number of runs as possible.
(*e*) State *four* variables under the control of the welder which will influence the weld profile.
(*f*) Name *two* other mechanized welding processes that could be used for welding the joints and state in *each* case *one* reason for using the process in preference to the submerged arc process.
(*g*) State in *each* case *one* advantage which may be obtained by using
  (1) alternating current for submerged arc welding,
  (2) direct current for submerged arc welding.

43 In relation to the plasma arc welding process
(*a*) reproduce the sketch shown in the figure and identify the
  (1) negative pole within the circuit,
  (2) shielding gas ports.
(*b*) State whether the parent metal forms part of the welding circuit when a non-transferred arc is used for welding.
(*c*) State a temperature within the temperature range of the arc.
(*d*) Sketch a transverse section through the weld made by means of a transferred arc on low-carbon steel 10 mm thick.

44 (*a*) List *four* variables under the control of the operator which will influence the quality of a resistance spot weld.

Question 43



(*b*) Low-carbon steel sheet has been resistance spot welded. State whether the welding current would need to be increased if this process was to be used for welding aluminium sheet of the same thickness.

(*c*) Describe the operational sequence used for making resistance butt welds in short lengths of 50 mm diameter low-carbon steel pipes of wall thickness 6 mm.

(*d*) (1) A number of steel studs having the form shown in the figure are to be welded to low-carbon steel plate. Describe, with the aid of a sketch, the operational sequence used to make a drawn arc stud welded joint.

(2) The figure shows a ceramic ferrule used in the drawn arc stud welding. Explain the purpose of the serrations.

45 Each term used in column *A* in the table is directly related to *one* of the terms used in the column *B*. Pair *each* of the terms listed in column *A* with its appropriate term in column *B*.

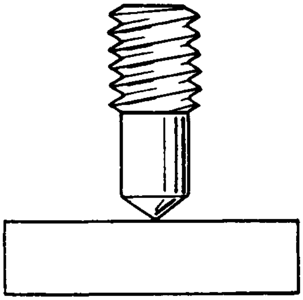
Column *A*	Column *B*
d.c. negative polarity	Force
Nugget	Oxy-fuel cutting
Kerf	Welding standard
API	Resistance spot welding
newton	Hard surfacing

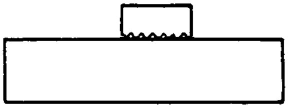
46 A box section column 750 mm square × 6500 mm long is to be fabricated from 40 mm thick low-carbon steel plate.

(*a*) Select and describe a suitable automatic welding process.

(*b*) Sketch the corner joint and show, if necessary, any edge preparation.

Question 44. (*d*) (1)





(*c*) Give *three* advantages of using automatic welding as opposed to manual metal-arc.

47 A spherical vessel, 3.6 m diameter, is fabricated from 75 mm thick low-carbon steel, the welding of the circumferential seams being carried out by the electroslag process.

(*a*) Sketch the macrostructure of the plate and weld area.

(*b*) Describe a suitable method of heat treatment to be carried out on completion of the welding.

(*c*) State *three* advantages to be obtained by the form of heat treatment chosen.

(*d*) State *two* safety precautions to be taken when pressure testing the vessel.

48 (*a*) Explain why the effect of electric shock is much less when using a flat characteristic instead of a drooping characteristic power source for welding.

(*b*) Name *two* gases which may be produced during arc welding operations which are harmful to the health of the welder.

49 (*a*) State *two* factors that should be considered before selecting a filler/electrode for a hard surfacing application.

(*b*) State *three* precautions which may be taken by the welder to control the level of dilution when surfacing using an arc welding process.

50 (*a*) The figure shows three views of a platform bracket. Using graph isometric paper, make an isometric sketch of the bracket in the direction of arrow *A*. Omit all hidden lines.

(*b*) Parts of the bracket are to be assembled and welded using the electrical resistance spot welding process.

(1) Outline the principles of electrical resistance spot welding.

(2) State why the stiffener shown at *B* could not be resistance spot welded for the design shown.

(3) Sketch a modification to the stiffener that would enable spot welding to be used.

(4) State *three* advantages of using the resistance spot welding process for welding the bracket in preference to a fusion welded process.

51 State *five* variables, other than electrode diameter, that will influence the production of an acceptable quality weld when using the mechanized flux shielded visible arc process.

52 Name *each* of the welding or thermal cutting processes illustrated in the figure. Identify your answer by stating the appropriate letter and name the process concerned.

53 (*a*) State *one* safety precaution that must be carried out.

   (1) when oxy-acetylene cutting inside a steel container,
   (2) when manual metal-arc welding galvanized steel,
   (3) when gas-shielded metal-arc welding inside a container.

(*b*) State why gas-shielded tungsten arc welding should not be carried out inside a container that has been degreased using carbon tetrachloride until all the degreasing compound and vapours have been removed.

54 The figure shows an aluminium–magnesium alloy safety rail which is to be welded by the gas-shielded metal-arc welding process using 1 mm diameter filler wire.

(*a*) State a suitable welding voltage and amperage setting for making the fillet joint shown at *A*, in the horizontal–vertical position.

55 The figure (*a*) shows a section of a joint being welded using the electroslag process.

(*a*) Name the parts identified in the sketch at points *A* and *B*.
(*b*) State why run-off plates are required to complete the weld.
(*c*) State whether or not an arc is maintained throughout electroslag welding.
(*d*) Explain why small additions of flux may require to be added during electroslag welding.
(*e*) Give *two* reasons why electroslag welds may require to be heat treated after welding.
(*f*) State *three* basic differences that exist between conventional electroslag welding and consumable guide welding.
(*g*) Sketch in section a cruciform joint made by electroslag welding.
(*h*) Figure (*b*) shows a joint in low-alloy steel set-up for fillet welding using the manual metal-arc welding process. Explain why the edge shown at *X* was oxy-acetylene flame cut, then machined before welding.

56 In relation to welded fabrications:

(*a*) state what is meant by the term brittle fracture,
(*b*) state *five* conditions in which an otherwise ductile steel may behave in a brittle manner after welding,
(*c*) name a test that may be used to assess the notch ductility of a steel,
(*d*) state *five* factors to be considered when selecting a manual metal-arc electrode to be used for a given application.

57 The figure shows a beam to be fabricated from low-alloy steel, using the gas-shielded metal-arc process with flux cored electrode wire.

(*a*) Using the carbon equivalent formula given, calculate the carbon equivalent of the steel beam when its composition is as shown in the table.
(*b*) Explain why steel components with a high carbon equivalent should be
  (1) pre-heated before welding is carried out,
  (2) immediately post-heated after welding.
(*c*) The figure shows that the flanges of the beam have been stiffened using gusset plates. Explain why the corners have been removed.
(*d*) Name the main stress acting on the underside of flange *B* if a load is applied to the beam in the direction of arrow *A*.

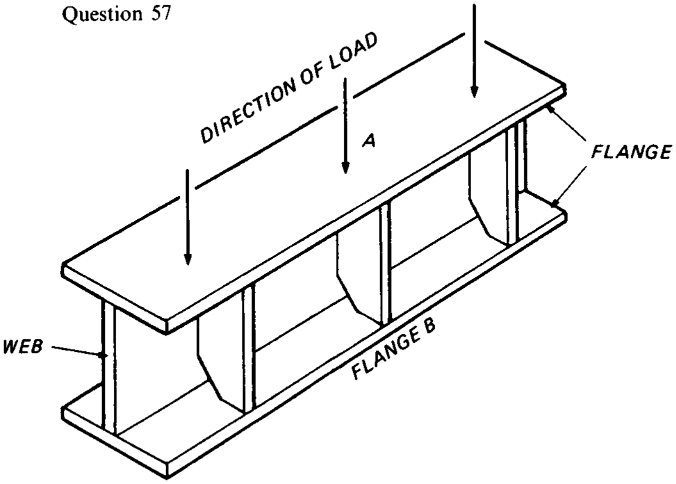
Composition	Carbon	Manganese	Silicon	Niobium	Vanadium	Remainder/ Iron
As a percentage	0.22	1.2	0.5	0.1	0.2	Sulphur and phosphorus in acceptable quantities

$$CE = C\% + \frac{Mn\%}{6} + \frac{Cr\% + Mn\% + V\%}{5} + \frac{Ni\% + Cu\%}{15}$$

(*e*) State *four* methods that may be used to reduce undercut at the toes of the welds joining the flanges to the web.

(*f*) Outline, with the aid of a sectional sketch, the effect of using too low a voltage setting for depositing a single run fillet weld by this process.

Question 57



Fabrication and welding engineering (technical grade)

1 (*a*) Give the main feature which distinguishes between cylinders for (1) combustible gas, and (2) non-combustible gas.
  (*b*) Explain the function of a 30 A fuse.
  (*c*) Why is a cylinder normally rolled to a slight overlap of the butting edges in a plate binding rolls?
  (*d*) Show, on an appropriate cross-section of rolled steel member, the correct positioning of a tapered washer.
  (*e*) State *four* factors which would ensure good quality soldering.
  (*f*) What information may be obtained by an examination of an etched cross-section of a fillet weld?
  (*g*) A large triangular plate of 30 mm thickness is lying on a workshop floor. Describe how the plate could be marked off to find its centre of area, for lifting purposes.
  (*h*) Give *five* reasons for using false wired edge on thin sheet metal.

2 (*a*) Explain the essential differences between ductility and malleability.
  (*b*) What is meant by (1) hardness and (2) toughness? Give practical examples of the use of these *two* properties in different materials.

3 Compare and contrast the following cutting processes: (1) oxy-fuel gas cutting, (2) guillotine cutting, with respect to:
  (*a*) cost,
  (*b*) limitations of cut,
  (*c*) type of material to be cut.

4 Discuss the factors which must be considered when deciding whether to form a given metal by hot or cold processes.

5 Describe, with the aid of sketches, *three* methods of stiffening and strengthening metal platework without the attachment of additional members.

6 When producing a riveted watertight butt joint, what are the important features to look for:
  (*a*) when setting up the work,
  (*b*) after riveting.

7 Explain the meaning of the following terms when used in connection with the control of distortion in welding:
  (*a*) preset,
  (*b*) restraint,

- (*c*) back-step,
- (*d*) intermittent,
- (*c*) staggered.

8 It is suggested that the following requirements are essential for safe and adequate electrical circuits in a fabrication workshop:

- (1) colour coding,
- (2) notices,
- (3) maintenance,
- (4) notification of faults,
- (5) earthing,
- (6) load protection,
- (7) insulation,
- (8) protection,
- (9) emergency switches.

Write explanatory notes on any *five* of the above.

9 With the aid of sketches of cross-section show *each* of the following weld defects:

- (*a*) undercut on a fillet weld,
- (*b*) undercut on a butt weld,
- (*c*) lack of root penetration in a fillet weld,
- (*d*) lack of penetration in an open square-edge butt joint,
- (*e*) excessive root penetration in a single bevel butt joint.

10 One hundred welded fabrications each weighing 48 kgf are at a temperature of 25 °C. They are placed in a furnace and heated to 500 °C for the purpose of stress relieving. Calculate the quantity of heat to be supplied so that the fabrications reach the required temperature. Specific heat capacity of the welded fabrication is 0.5 kJ kg °C. Furnace efficiency is 20%.

PREFACE

No truly authoritative dictionary can be the work of one person. Rather, it is the culmination of the unceasing efforts of many people. The field of electronics is constantly expanding and so its language and vocabulary must be augmented with newly originated words and phrases if effective communication of thoughts and ideas are to be established. The originators give the words their initial meanings, but the exact definitions change with technological advances and actual usage by others.

The content of this dictionary is thus an analysis of words and their meanings as determined by common usage, and as researched and written by its author and editors. Because the field of electronics is constantly expanding, its language and vocabulary must grow along with it. More than 4000 new terms and additions to existing terms have been added in this third edition. Many of the new terms are related to fields, phenomena, or processes that were little-known or even nonexistent when the first edition was published in 1962.

Every entry in the second edition was reviewed and many were revised for this new book in order to keep pace with current usage. Where more than one definition exists for a term, the different meanings are arranged numerically. This method, however, does not necessarily imply a preferred order of meanings.

The emphasis of this dictionary is on the broad subject of electronics. Within this field it contains over 16,000 definitions of current terms from radio, television, communications, radar, electronic instrumentation, industrial and medical electronics, microelectronics, computers, data processing, lasers, logic, semiconductors, and fiberoptics.

I gratefully acknowledge the permission granted once again by Mr. E. K. Gannett of the IEEE to use definitions and illustrations which originally were prepared by them. My thanks also go to the other organizations and trade sources who have so kindly supplied their material and granted permission to use it.

I should like to take this opportunity to dedicate this book to my children, Jeffrey and Debbie, while at the same time extending gratitude to my lovely wife Bettina, whose untiring efforts and truly invaluable assistance have made it possible for me to prepare this edition of the dictionary.

Samuel Johnson once said, "Dictionaries are like watches. The worst is better than none, and the best cannot expect to be quite true." With that thought in mind, the users of this volume are cordially invited to submit to the publisher comments and suggestions for additions or changes of definitions given here, so that future editions will better reflect the current usage of the language of electronics.

Rudolf F. Graf

HOW TO USE THIS DICTIONARY

This Modern Dictionary of Electronics follows the standards accepted by prominent lexicographers. All terms of more than one word are treated as one word. For example, "bridged-T network" appears between "bridged tap" and "bridge duplex system." Abbreviations are also treated alphabetically; the initials "ARRL" follow the term "arrester" rather than appearing at the beginning of the A's.

For ease in quickly locating a specific term, catchwords for the first and last entries which appear on each page are shown at the top.

Illustrations have been positioned with the terms they depict and are clearly captioned so they can be immediately associated with the proper definition.

Moderate cross-referencing has been used as an aid in locating terms which you might look for in more than one place. For example, when looking up "Esaki diode" you'll be referred to "tunnel diode." However, occasionally you may look for a term and not find it. In such instances, always think of the term in its most logical form; i.e., you will find "acoustic resonator" in the A's and not in the R's. In other words, when looking up the definition for a specific device, such as a "dipole antenna," refer to the modifier "dipole" rather than to "antenna."

A unique feature is the *Pronunciation Guide* beginning after the definitions. This Guide shows syllabic division and pronunciations, based on accepted industry usage, for over 1100 commonly mispronounced words. Because the language is in constant flux, pronunciations and spellings acceptable five years ago may be obsolete today. Witness the evolution of the word "ampere." Originally it was pronounced "AHMpair," the French pronunciation. In this country, accepted usage simplified the term to "AMpeer" (just as "Schmidt" became "Smith"). Today the accepted pronunciation is "AMper."

Since it follows the most authoritative standards of the industry, this dictionary will serve as an excellent guide on spelling, hyphenation, abbreviation, capitalization, etc.

It is hoped you will find Modern Dictionary of Electronics helpful, informative, and satisfactory in every way. Should you care to pass along any comments or suggestions which come to mind as a result of its use, we will be most happy to hear from you.

Howard W. Sams

A

A—1. Abbreviation for angstrom unit, used in expressing wavelength of light. Its length is 10^{-8} centimeter. 2. Chemical symbol for argon, an inert gas used in some electron tubes. 3. Symbol for area of a plane surface.

a—1. Abbreviation for atto (10^{-18}). 2. Abbreviation for ampere.

A− (A-minus or A-negative)—Sometimes called F−. Negative terminal of an A-battery or negative polarity of other sources of filament voltage. Denotes the terminal to which the negative side of the filament-voltage source should be connected.

A+ (A-plus or A-positive)—Sometimes called F+. Positive terminal of an A-battery or positive polarity of other sources of filament voltage. The terminal to which the positive side of the filament voltage source should be connected.

ab—The prefix attached to names of practical electric units to indicate the corresponding unit in the cgs (centimeter grams second) electromagnetic systems—e.g., abampere, abvolt, abcoulomb.

abac—*See* Alignment Chart.

abampere—Centimeter-gram-second electromagnetic unit of current. The current which, when flowing through a wire one centimeter long bent into an arc with a radius of one centimeter, produces a magnetic field intensity of one oersted. One abampere is equal to 10 amperes.

A-battery—Source of energy which heats the filaments of vacuum tubes in battery-operated equipment.

abc—Abbreviation for automatic bass compensation, a circuit used in some equipment to increase the amplitude of the bass notes to make them appear more natural at low volume settings.

abcoulomb—Centimeter-gram-second electromagnetic unit of electrical quantity. The quantity of electricity passing any point in an electrical circuit in one second when the current is one abampere. One abcoulomb is equal to 10 coulombs.

aberration—In lenses a defect that produces inexact focusing. Aberration may also occur in electron optical systems, causing a halo around the light spot.

abfarad—Centimeter-gram-second electromagnetic unit of capacitance. The capacitance of a capacitor when a charge of one abcoulomb produces a difference of potential of one abvolt between its plates. One abfarad is equal to 10^{9} farads.

abhenry—Centimeter-gram-second electromagnetic unit of inductance. The inductance in a circuit in which an electromotive force of one abvolt is induced by a current changing at the rate of one abampere per second. One abhenry is equal to 10^{9} henrys.

abmho—Centimeter-gram-second electromagnetic unit of conductance. A conductor or circuit has a conductance of one abmho when a difference of potential of one abvolt between its terminals will cause a current of one abampere to flow through the conductor. One abmho is equal to 10^{9} mho.

abnormal glow—In a glow tube, a current discharge of such magnitude that the cathode area is entirely surrounded by a glow. A further increase in current results in a rise in its density and a drop in voltage.

abnormal propagation—The phenomenon of unstable or changing atmospheric and/or inospheric conditions acting upon transmitted radio waves. Such waves are prevented from following their normal path through space, causing difficulties and disruptions of communications.

abnormal reflections—*See* Sporadic Reflections.

abohm—Centimeter-gram-second electromagnetic unit of resistance. The resistance of a conductor when, with an unvarying current of one abampere flowing through it, the potential difference between the ends of the conductor is one abvolt. One abohm is equal to 10^{-9} ohm.

abort—To cut short or break off (an action, operation, or procedure) with an aircraft, guided missile, or the like—especially because of equipment failure. An abort may occur at any point from start to countdown or takeoff to the destination. An abort can be caused by human technical or meteorological errors, miscalculation, or malfunctions.

AB power pack—Assembly in a single unit of the A- and B-batteries of a battery-operated circuit. Also, a unit that supplies the necessary A and B voltages from an a-c source of power.

abrasion machine—A laboratory device for determining the abrasive resistance of wire or cable. The two standard types of machines are the squirrel cage with square steel bars and the abrasive grit types.

abrasion resistance—A measure of the ability of a wire or wire covering to resist damage due to mechanical causes. Usually expressed as inches of abrasive tape travel.

abscissa—Horizontal, or X-, axis on a chart or graph.

absolute address—An address used to specify the location in storage of a word in a computer program, not its position in the program.

absolute altimeter—Electronic instrument which furnishes altitude data with regard to the surface of the earth or any other surface immediately below the instrument—as distinguished from an aneroid altimeter, the readings of which depend on air pressure.

absolute altitude—Altitude with respect to the earth's surface, as differentiated from the altitude with respect to sea level.

absolute code—A code using absolute addresses and absolute operation codes—i.e., a code that indicates the exact location where the reference operand is to be found or stored.

absolute coding—Computer coding using absolute addresses.

absolute delay—The time interval between the transmission of two synchronized radio, loran, or radar signals from the same or different stations.

absolute efficiency—Ratio of the actual output of a transducer to that of a corresponding ideal transducer under similar conditions.

absolute error—1. The amount of error expressed in the same units as the quantity containing the error. 2. Loosely, the absolute value of the error—i.e., the magnitude of the error without regard to its algebraic sign.

absolute gain of an antenna—The gain in a given direction when the reference antenna is an isotropic antenna isolated in space.

absolute humidity—Amount of water vapor present in a unit volume of atmosphere.

absolute maximum rating—Limiting values of operating and environmental conditions, applicable to any electron device of a specified type as defined by its published data, and not to be exceeded under the worst probable conditions. Those ratings beyond which the life and reliability of a device can be expected to decline.

absolute minimum resistance—The resistance between the wiper and the termination of a potentiometer, when the wiper is adjusted to minimize that resistance.

absolute Peltier coefficient—The product of the absolute temperature and the absolute Seebeck coefficient of a material.

absolute pressure—Pressure of a liquid or gas measured relative to a vacuum (zero pressure).

absolute pressure transducer — A pressure transducer that accepts simultaneously two independent pressure sources, and the output of which is proportional to the pressure difference between the sources.

absolute scale—*See* Kelvin Scale.

absolute Seebeck coefficient—The integral from absolute zero to the given temperature of the quotient of the Thomson coefficient of a material divided by its absolute temperature.

absolute system of units—Also called coherent system of units. A system of units in which a small number of units is chosen as fundamental—e.g., units of mass, length, time, and charge. Such units are termed absolute units. All other units are derived from them by taking a definite proportional factor in each of those laws which is chosen as the basic laws for expressing the relationships between the physical quantities. The proportional factor is generally taken as unity.

absolute temperature—Temperature measured from absolute zero, a theoretical level defined as −273.2°C or −459.7°F or 0°K.

absolute units—A system of units based on physical principles, in which a small number of units are chosen as fundamental and all other units derived from them—i.e. abohm, abcoulomb, abhenry, etc.

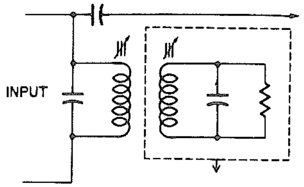
absolute value—The numerical value of a number or symbol without reference to its algebraic sign. Thus, $|3|$ is the absolute value of +3 or −3. An absolute value is signified by placing vertical lines on both sides of the number or symbol.

absolute value device—A computing element that produces an output equal to the magnitude of the input signal, but always of one polarity.

absolute zero—Lowest possible point on the scale of absolute temperature; the point at which all molecular activity ceases. Absolute zero is defined as −273.2°C, −459.7°F, or 0°K.

absorber—1. In a nuclear reactor, a substance that absorbs neutrons without reproducing them. Such a substance may be useful in control of a reactor or, if unavoidably present, may impair the neutron economy. 2. Any material or device which absorbs and dissipates radiated energy.

absorption—1. Dissipation of the energy of a radio or sound wave into other forms as a result of its interaction with matter. 2. The process by which the number of particles or photons entering a body of matter is reduced by interaction of the particle or radiation with the matter. Similarly, the reduction of the energy of a particle while traversing a body of matter. This term is sometimes erroneously used for capture. 3. Penetration of a substance into the body of another.



Absorption circuit.

absorption circuit—A tuned circuit that dissipates energy taken from another circuit.

absorption coefficient—1. Measure of sound-absorbing characteristics of a unit area of a given material, compared with the sound-absorbing characteristics of an open space (total absorption) having the same area. 2. Ratio or loss of intensity caused by absorption, to the total original intensity of radiation.

absorption control—Control of a nuclear reactor by use of a neutron absorber. Adjustment is made by varying the effective amount of absorber in or near the core. The most common arrangement is to incorporate the absorber in rods which can be moved in or out to produce the desired effect.

absorption current — The current flowing into a capacitor following its initial charge, due to a gradual penetration of the electric stress into the dielectric. Also, the current which flows out of a capacitor following its initial discharge.

absorption dynamometer—An instrument for measuring power, in which the energy of a revolving wheel or shaft is absorbed by the friction of a brake.

absorption fading—A slow type of fading, primarily caused by variations in the absorption rate along the radio path.

absorption frequency meter—*See* Absorption Wavemeter.

absorption loss—That part of transmission loss due to dissipation or conversion of electrical energy into other forms (e.g., heat), either within the medium or attendant upon a reflection.

absorption marker—A sharp dip on a frequency-response curve due to the absorption of energy by a circuit sharply tuned to the frequency at which the dip occurs.

absorption modulation — Also called loss modulation. A system for amplitude-modulating the output of a radio transmitter by means of a variable-impedance device (such as a microphone or vacuum-tube circuit) inserted into or coupled to the output circuit.

absorption trap — A parallel-tuned circuit coupled either magnetically or capacitively to absorb and attenuate interfering signals.

absorption wavemeter—Also called absorption frequency meter. An instrument for measuring frequency. Its operation depends on the use of a tuned electrical circuit or cavity loosely coupled to the source. Maximum energy will be absorbed at the resonant frequency, as indicated by a meter or other device. Frequency can then be determined by reference to a calibrated dial or chart.

absorptivity—A measure of the portion of incident radiation or sound energy absorbed by a material.

A-B test—Direct comparison of two sounds by playing first one and then the other. May be done with two tape recorders playing identical tapes (or the same tape), two speakers playing alternately from the same tape recorder, or two amplifiers playing alternately through one speaker, etc.

abvolt—Centimeter-gram-second electromagnetic unit of potential difference. The potential difference between two points when one erg of work is required to transfer one abcoulomb of positive electricity from a lower to a higher potential. An abvolt is equal to 10^{-8} volt.

ac—Abbreviation for alternating current.

a-c bias—The alternating current, usually of a frequency several times higher than the highest signal frequency, that is fed to a record head in addition to the signal current. The a-c bias serves to linearize the recording process.

accelerating conductor or relay—One which causes the operation of a succeeding device to begin in the starting sequence after the proper conditions have been established.

accelerating electrode—An electrode in a cathode-ray or other electronic tube to which a positive potential is applied to increase the velocity of electrons or ions toward the anode. A klystron tube does not have an anode but does have accelerating electrodes.

acceleration—The rate of change in velocity. Often expressed as a multiple of the acceleration of gravity ($g = 32.2$ ft/sec^2).

acceleration at stall—The value of servomotor angular acceleration calculated from the stall torque of the motor and the moment of inertia of the rotor. Also called torque-to-inertia ratio.

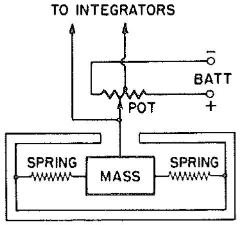
acceleration switch—A type of limit switch which senses acceleration forces above a preset value and in a particular direction. Commonly used in aerospace equipment, it triggers sensors or arming networks when a specific gravitational force has been reached.

acceleration time—In a computer, the elapsed time between the interpretation of instructions to read or write on tape and the possibility of information transfer from the tape to the internal storage, or vice versa.

acceleration voltage — Potential between a cathode and anode or other accelerating element in a vacuum tube. Its value determines the average velocity of the electrons.

accelerator—A device for imparting a very high velocity to charged particles such as electrons or protons. Fast-moving particles of this type are used in research or in studying the structure of the atom itself.

accelerator dynamic test—A test performed on an accelerometer by means of which information is gathered pertaining to the overall behavior frequency response and/or natural frequency of the device.



Accelerometer.

accelerometer — An instrument or device, often mounted in an aircraft, guided missile, or the like; used to sense accelerative forces and convert them into corresponding electrical quantities usually for measuring, indicating or recording purposes. It does not measure velocity or distance, only changes in velocity.

accentuation—Also called pre-emphasis. The emphasizing of any certain band of frequencies, to the exclusion of all others, in an amplifier or electronic device. Applied particularly to the higher audio frequencies in frequency-modulated (f-m) transmitters.

accentuator—Network or circuit used for pre-emphasis or increase in amplitude of a given band of frequencies, usually audio.

acceptable-environmental-range test — A test to determine the range of environmental conditions for which an equipment maintains at least the minimum required reliability.

acceptable quality level—The maximum percentage of defective components considered to be acceptable as an average for a process or the lowest quality a supplier is permitted to present continually for acceptance. (Abbreviated AQL.)

acceptance sampling plan—A plan for the inspection of a sample as a basis for acceptance or rejection of a lot or taking another sample.

acceptance test—A test to demonstrate the degree of compliance of a purchaser's equipment with his requirements and specifications.

acceptor—Also called acceptor impurity. An impurity lacking sufficient valence electrons to complete the bonding arrangement in the crystal structure. When added to a semiconductor crystal, it accepts an electron from a neighboring atom and thus creates a hole in the lattice structure of the crystal.

acceptor circuit—A circuit which offers minimum opposition to a given signal.

acceptor impurity—*See* Acceptor.

access arm—In a computer storage unit, a mechanical device which positions the reading and writing mechanism.

access time—Also called waiting time. The time interval between the instant a memory or storage device requests information and the instant this information begins to be available in useful form.

a-c circuit breaker—A device which is used to close and interrupt an a-c power circuit under normal conditions, or to interrupt this circuit under faulty or emergency conditions.

accompaniment manual — In an organ, the keyboard used for playing the accompaniment to the melody. Also called the lower manual, or great manual.

accompanying audio (sound) channel—Also known as co-channel sound frequency. The r-f carrier frequency which supplies the sound to accompany a television picture.

accordion—A type of contact used in some printed-circuit connectors. The contact spring is given a *z* shape to permit high deflection without excessive stress.

a-c coupling—Coupling of one circuit to another circuit through a capacitor or other device which passes the varying portion but not the static (d-c) characteristics of an electrical signal.

accumulator—In an electronic computer, a device which stores a number and which, on receipt of another number, adds the two and stores the sum. An accumulator may have properties such as shifting, sensing signals, clearing, complementing, and so forth.

accuracy—1. The maximum error in the measurement of a physical quantity in terms of the output of an instrument when referred to the individual instrument calibration. Usually given as a percentage of full scale. 2. The quality of freedom from mistake or error in an electronic computer—that is, of conformity to truth or to a rule.

accuracy rating of an instrument — The limit, usually expressed as a percentage of full-scale value, not exceeded by errors when the instrument is used under reference conditions.

ac/dc—Electronic equipment capable of operation from either an a-c or d-c primary power source.

a-c/d-c receiver—A radio receiver designed to operate directly from either an a-c or a d-c source.

a-c directional overcurrent relay—A device which functions on a desired value of a-c overcurrent flowing in a predetermined direction.

a-c dump—The intentional, accidental, or conditional removal of all alternating-current power from a system or component. An a-c dump usually results in the removal of all power, since direct current is usually supplied through a rectifier or converter.

a-c erasing head—In magnetic recording, a device using alternating current to produce the magnetic field necessary for removal of previously recorded information.

acetate—A basic chemical compound in the mixture used to coat recording discs.

acetate base—The transparent plastic film which forms the tough backing for acetate magnetic recording tape.

acetate disc—A mechanical recording disc, either solid or laminated, made mostly from cellulose nitrate lacquer plus a lubricant.

acetate tape—A sound-recording tape with a smooth, transparent acetate backing. One side is coated with an oxide capable of being magnetized.

a-c generator—1. A rotating electrical machine that converts mechanical power into alternating current. Also known as an alternator. 2. A device, usually an oscillator, designed for the purpose of producing alternating current.

A-channel—One of two stereo channels (usually the left) to the microphones, speakers, or other equipment associated with this channel.

achieved reliability—Reliability determined on the basis of actual performance of nominally identical items under equivalent environmental conditions. Also called operational reliability.

achromatic—1. In color television, a term meaning a shade of gray from black to white, or the absence of color (without color). 2. Black-and-white television, as distinguished from color television. 3. A term applied to lenses, signifying their more or less complete correction for chromatic aberration.

achromatic lens—A lens which has been corrected for chromatic aberration. Such a lens is capable of bringing all colors of light rays to approximately the same point of focus. This it does by combining a concave lens of flint glass with a convex lens of crown glass.

achromatic locus—Also called achromatic region. On a chromaticity diagram an area that contains all points representing acceptable reference white standards.

achromatic region—*See* Achromatic Locus.

acid—A chemical compound which dissociates and forms hydrogen ions when in aqueous solution.

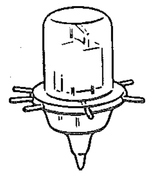
acid depolarizer—An acid, such as nitric acid, sometimes introduced into a primary cell to prevent polarization.

aclinic line—Also called isoclinic line. On a magnetic map, an imaginary line which connects points of equal magnetic inclination or dip.

a-c magnetic biasing—In magnetic recording, the method used to remove random noise and/or previously recorded material from the wire or tape. This is done by introducing an alternating magnetic field at a substantially higher frequency than the highest frequency to be recorded.

a-c noise—Noise which displays a rate of change which is fast relative to the response capability of the device.

a-c noise immunity—A measure of a logic circuit's ability to maintain the prescribed logic state in the presence of such noise. It is defined in terms of the amplitude and pulse width of an input noise signal to which the element will not respond.



Acorn tube.

acorn tube—A button- or acorn-shaped vacuum tube with no base, for uhf applications. Electrodes are brought out through the glass envelope on the side, top, and bottom.

acoustic—Also acoustical. Pertaining to sound or the science of sound.

acoustic absorption loss—The energy lost by conversion into heat or other forms when sound passes through or is reflected by a medium.

acoustic absorptivity—The ratio of sound energy absorbed by a surface to the sound energy arriving at the surface. Equal to 1 minus the reflectivity of the surface.

acoustical attenuation constant—The real part of the acoustical propagation constant. The commonly used unit is the neper per section or per unit distance.

acoustical-electrical transducer — A device designed to transform sound energy into electrical energy and vice versa.

acoustical mode — A mode of crystal-lattice vibration that does not produce an oscillating dipole.

acoustical ohm—A measure of acoustic resistance, reactance, or impedance. One acoustical ohm is equal to a volume velocity of 1 cubic centimeter per second when produced by a sound pressure of 1 microbar.

acoustical phase constant—The imaginary part of the acoustical propagation constant. The commonly used unit is the radian per section or per unit distance.

acoustical reflectivity—*See* Sound-Reflection Coefficient.

acoustical transmittivity—*See* Sound-Transmission Coefficient.

acoustic burglar alarm—Also called acoustic intrusion detector. A burglar alarm that is responsive to sounds produced by an intruder. Concealed microphones connected to an audio amplifier trip an alarm when sounds exceed a predetermined normal level.

acoustic capacitance—In a sound medium, a measure of volume displacement per dyne per square centimeter. The unit is centimeter to the fifth power per dyne.

acoustic clarifier—A system of cones loosely attached to the baffle of a speaker and designed to vibrate and absorb energy during sudden loud sounds, thereby suppressing them.

acoustic compliance—1. The measure of volume displacement of a sound medium when subjected to sound waves. 2. That type of acoustic reactance which corresponds to capacitive reactance in an electrical circuit.

acoustic delay line—A device which retards one or more signal vibrations by causing them to pass through a solid or liquid.

acoustic depth finder—*See* Fathometer.

acoustic dispersion — The change of the speed of sound with frequency.

acoustic elasticity—1. The compressibility of the air in a speaker enclosure as the cone moves backward. 2. The compressibility of any material through which sound is passed.

acoustic feedback—Also called acoustic regeneration. The mechanical coupling of a portion of the sound waves from the output of an audio-amplifying system to a preceding part or input circuit (such as the microphone) of the system. When excessive, acoustic feedback will produce a howling sound in the speaker.

acoustic filter — A sound-absorbing device that selectively suppresses certain audio frequencies while allowing others to pass.

acoustic frequency response—The voltage-attenuation frequency measured into a resistive load, producing a bandwidth approaching sufficiently close to the maximum.

acoustic generator—A transducer such as a speaker, headphones, or a bell, which converts electrical, mechanical, or other forms of energy into sound.

acoustic homing system—A missile guidance system which responds to noise radiated by the target.

acoustic horn—Also called horn. A tube of varying cross section having different terminal areas which change the acoustic impedance to control the directivity of the sound pattern.

acoustic impedance—Total opposition of a medium to sound waves. Equal to the force per unit area on the surface of the medium, divided by the flux (volume velocity or linear velocity multiplied by area) through that surface. Expressed in ohms and equal to the mechanical impedance divided by the square of the surface area. One unit of acoustic impedance is equal to a volume velocity of one cubic centimeter per second produced by a pressure of 1 microbar. Acoustic impedance contains both acoustic resistance and acoustic reactance.

acoustic inertance—A type of acoustic reactance which corresponds to inductive reactance in an electrical circuit. (The resistance to movement or reactance offered by the sound medium because of the inertia of the effective mass of the medium.) Measured in acoustic ohms.

acoustic intensity—The limit approached by the quotient of acoustical power being transmitted at a given time through a given area divided by the area as the area approaches zero.

acoustic interferometer—An instrument for measuring the velocity or frequency of sound waves in a liquid or gas. This is done by observing the variations of sound pressure in a standing wave, established in the medium between a sound source and a reflector, as the reflector is moved or the frequency is varied.

acoustic intrusion detector—*See* Acoustic Burglar Alarm.

acoustic labyrinth—Special speaker enclosure having partitions and passages to prevent cavity resonance and to reinforce bass response.

acoustic lens—An array of obstacles that refract sound waves in the same way that an optical lens refracts light waves. The dimensions of these obstacles are small compared to the wavelengths of the sounds being focused.

acoustic line—Mechanical equivalent of an electrical transmission line. Baffles, labyrinths, or resonators are placed at the rear of a speaker to help reproduce the very low audio frequencies.

acoustic memory—A computer memory using an acoustic delay line. The line employs a train of pulses in a medium such as mercury or quartz.

acoustic mine—Also called sonic mine. An underwater mine that is detonated by sound waves, such as those from a ship's propeller or engines.

acoustic mirage—The distortion of a sound wavefront by a large temperature gradient in air or water. This creates the illusion of two sound sources.

acoustic ohm—The unit of acoustic resistance, reactance, or impedance. One acoustic ohm is present when a sound pressure of 1 dyne per square centimeter produces a volume velocity of 1 cubic centimeter per second.

acoustic phase constant—The imaginary part of the acoustic propagation constant. The commonly used unit is the radian per section or per unit distance.

acoustic pickup — In nonelectrical phonographs, the method of reproducing the material on a record by linking the needle directly to a flexible diaphragm.

acoustic radiator — In an electroacoustic transducer, the part that initiates the radiation of sound vibration. A speaker cone or headphone diaphragm is an example.

acoustic radiometer — An instrument for measuring sound intensity by determining the unidirectional steady-state pressure caused by the reflection or absorption of a sound wave at a boundary.

acoustic reactance—That part of acoustic impedance due to the effective mass of the medium—that is, to the inertia and elasticity of the medium through which the sound travels. The imaginary component of acoustic impedance and expressed in acoustic ohms.

acoustic reflectivity—The ratio of the rate of flow of sound energy reflected from the surface on the side of incidence, to the incident rate of flow.

acoustic refraction—A bending of sound waves when passing obliquely from one medium to another in which the velocity of sound is different.

acoustic regeneration — *See* Acoustic Feedback.

acoustic resistance — That component of acoustic impedance responsible for the dissipation of energy due to friction between molecules of the air or other medium through which sound travels. Measured in acoustic ohms and analogous to electrical resistance.

acoustic resonance—An increase in sound intensity as reflected waves and direct waves which are in phase combine. May also be due to the natural vibration of air columns or solid bodies at a particular sound frequency.

acoustic resonator—An enclosure which intensifies those audio frequencies at which the enclosed air is set into natural vibration.

acoustics—1. Science of production, transmission, reception, and effects of sound. 2. In a room or other location, those characteristics which control reflections of sound waves and thus the sound reception in it.

acoustic scattering — The irregular reflection, refraction, or diffraction of a sound wave in many directions.

acoustic shock—Physical pain, dizziness, and sometimes nausea brought on by hearing a loud, sudden sound.

acoustic system—Arrangement of components in devices designed to reproduce audio frequencies in a specified manner.

acoustic transmission system—An assembly of elements adapted for the transmission of sound.

acoustic treatment—Use of certain sound-absorbing materials to control the amount of reverberation in a room, hall, or other enclosure.

acoustic wave—A traveling vibration by which sound energy is transmitted in air, in water, or in the earth. The characteristics of these waves may be described in terms of change of pressure, of particle displacement, or of density.

acoustic wave filter—A device designed to separate sound waves of different frequencies. (Through electroacoustic transducers, such a filter may be associated with electric circuits.)

acoustoelectric effect—Generation of an electric current in a crystal by a traveling longitudinal sound wave.

a-c plate resistance—Also called dynamic plate resistance. Internal resistance of a vacuum tube to the flow of alternating current. Expressed in ohms, the ratio of a small change in plate voltage to the resultant change in plate current, other voltages being held constant.

a-c power supply—A power supply that provides one or more a-c output voltages—e.g., a-c generator, dynamotor, inverter, or transformer.

acquisition—1. The process of locating the orbit of a satellite or trajectory of a space probe so that tracking or telemetry data can be gathered. 2. The process of pointing an antenna or telescope so that it is properly oriented to allow gathering of tracking or telemetry data from a satellite or space probe.

acquisition and tracking radar—A radar set which locks on to a strong signal and tracks the object emitting or reflecting the signal. May be airborne or on the ground. Tracking radars use a dish-type antenna reflector to produce a searchlight-type beam.

acquisition radar—A radar set that detects an approaching target and feeds approximate position data to a fire-control or missile-guidance radar, which then takes over the function of tracking the target.

a-c receiver—A radio receiver designed to operate from an a-c source only.

a-c reclosing relay—A device which controls the automatic reclosing and locking out of an a-c circuit interrupter.

a-c relay—A relay designed to operate from an alternating-current source.

a-c resistance—Total resistance of a device in an a-c circuit. (*Also see* High-Frequency Resistance.)

a-c time overcurrent relay—A device which has either a definite or an inverse time characteristic and functions when the current in an a-c circuit exceeds a predetermined value.

actinic—In radiation, the property of producing a chemical change, such as the photographic action of light.

actinium—A radioactive element discovered in pitchblende by the French chemist Debierne in 1889. Its atomic number is 89; its atomic weight, 227.

actino electric effect—The property of some special materials whereby when an electric current is impressed on them, their resistance changes with light.

actino electricity—Electricity produced by the action of radiant energy on crystals.

actinometer—An instrument that measures the intensity of radiation by determining the amount of fluorescence produced by that radiation.

action area—In the rectifying junction of a metallic rectifier, that portion which carries the forward current.

action current—A brief and very small electric current which flows in a nerve during a nervous impulse.

action potential—The instantaneous value of the voltage between excited and resting portions of an excitable living structure.

activation—1. Making a substance artificially radioactive by placing it in an accelerator such as a cyclotron, or by bombarding it with neutrons. 2. To treat the cathode or target of an electron tube in order to create or increase its emission. 3. The process of adding electrolyte to a cell to make it ready for operation.

activation time—The time interval from the moment activation is initiated to the moment the desired operating voltage is obtained in a cell or battery.

activator—An additive that improves the action of an accelerator.

active area—The portion of the rectifying junction of a metallic rectifier that carries forward current.

active communications satellite—*See* Active Comsat.

active component—1. An electrical or electronic element capable of controlling voltages or currents to produce gain or switching action in a circuit (e.g., transistor, vacuum tube, or saturable reactor). Also called active device, or active element. 2. A device, the output of which is dependent on a source of power other than the main input signal.

active comsat—Also called active communication satellite. A communication satellite in which on-board receivers and transmitters receive signals beamed at them from a ground terminal, amplify them greatly, and retransmit them to another ground terminal. Less sensitive receivers and less powerful transmitters can be used on the ground than are needed for passive comsats.

active current—In an alternating current, a component in phase with the voltage. The working component as distinguished from the idle or wattless component.

active decoder—A device that is associated with a ground station and automatically indicates the radar beacon reply code that is received in terms of its number or letter designation.

active device—*See* Active Component.

active electric network—An electric network containing one or more sources of energy.

active element—*See* Active Component.

active filter—A device employing passive network elements and amplifiers. It is used for transmitting or rejecting signals in certain frequency ranges, or for controlling the relative output of signals as a function of frequency.

active guidance—*See* Active Homing.

active homing—Also called active guidance. A missile system using a radar system in the missile itself to provide target information and to guide itself to the target.

active infrared detection—An infrared detection system in which a beam of infrared rays is transmitted toward one or more possible targets, and the rays reflected from the target are detected.

active jamming—Intentional radiation or reradiation of electromagnetic waves to impair the use of a specific portion of the electromagnetic-wave spectrum.

active leg—Within a transducer, an electrical element which changes its electrical characteristics as a function of the applied stimulus.

active line—A horizontal line which produces the tv picture, as opposed to the lines occurring during blanking (horizontal and vertical retrace).

active maintenance downtime—The time during which work is actually being done on an item from the recognition of an occurrence of failure to the time of restoration to normal operation. This includes both preventive and corrective maintenance.

active material—1. In the plates of a storage battery, lead oxide or some other active substance which reacts chemically to produce electrical energy. 2. The fluorescent material, such as calcium tungstate, used on the screen of a cathode-ray tube.

active mixer and modulator—A device requiring a source of electrical power and using nonlinear network elements to heterodyne or combine two or more electrical signals.

active network—A network containing passive and active (gain) elements.

active pressure—In an a-c circuit, the pressure which produces a current, as distinguished from the voltage impressed upon the circuit.

active RC network—A network formed by resistors, capacitors, and active elements.

active repair time—That portion of corrective maintenance downtime during which repair work is being done on the item, including preparation, fault-location, part-replacement, adjustment and recalibration, and final test time. It may also include part procurement time under shipboard or field conditions.

active satellite—A satellite which receives, regenerates, and retransmits signals between stations. *See also* Communications Satellite.

active sonar—*See* Sonar.

active substrate—A substrate in which active elements are formed to provide discrete or integrated devices. Examples of active substrates are single crystals of semiconductor materials within which are transistors, resistors, and diodes, or combinations of these elements. Another example is ferrite substrates within which electromagnetic fields are used to perform logical, gating, or memory functions.

active systems—In radio and radar, systems which require transmitting equipment, such as a beacon or transponder, to be carried in the vehicle.

active tracking system—Usually, a system which requires the addition of a transponder or responder on board the vehicle to repeat or retransmit information to the tracking equipment—e.g., dovap, secor, azusa.

active transducer—A type of transducer in which its output waves depend on one or more sources of power, apart from the actuating waves.

active wire—The wire of an armature winding that produces useful voltage. That portion of the winding in which induction takes place.

activity—1. In a piezoelectric crystal, the magnitude of oscillation relative to the exciting voltage. 2. The intensity of a radioactive source. 3. Operations that result in the use or modification of the information in a computer file.

activity curve—A graph showing how the activity of a radioactive source varies with time

activity ratio—The ratio of the number of records in a computer file which have activity to the total number of records in the file.

a-c transducer—A transducer which, for proper operation, must be excited with alternating currents only. Also a device, the output of which appears in the form of an alternating current.

actual power—The average of values of instantaneous power taken over 1 cycle.

actuating system—1. In a device or vehicle, a system that supplies and transmits energy for the operation of a mechanism or other device. 2. A manually or automatically operated mechanical or electrical device which operates electrical contacts to effect signal transmission.

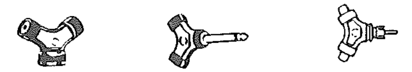
actuating time—The time at which a specified contact functions.

actuator—1. In a servo system, the device which moves the load. 2. The part of a relay that converts electrical energy into mechanical motion.

a-c voltage—*See* Alternating Voltage.

acyclic machine—A direct-current machine in which the voltage generated in the active conductors maintains the same direction with respect to those conductors at all times.

adapter—A fitting designed to change the terminal arrangement of a jack, plug, socket, or other receptacle, so that other than the original electrical connections are possible.



Adapter.

adaptive control system—A device the parameters of which are automatically adjusted to compensate for changes in the dynamics of the process to be controlled. An afc circuit utilizing temperature-compensating capacitors to correct for temperature changes is an example.

adaptive telemetry—Telemetry having the ability to select certain vital information or any change in a given signal.

Adcock antenna—A pair of vertical antennas separated by one-half wavelength or less and connected in phase opposition to produce a figure-8 directional pattern.

Adcock direction finder—A radio direction finder using one or more pairs of Adcock antennas for directional reception of vertically polarized radio waves.

Adcock radio range—A type of radio range utilizing four vertical antennas (Adcock antennas) placed at the corners of a square, with a fifth antenna in the center.

a-d converter—Abbreviation for analog-to-digital converter.

add-and-subtract relay—A stepping relay capable of being operated so as to rotate the movable contact arm in either direction.

addend—A quantity which, when added to another quantity (called the augend), produces a result called the sum.

adder—1. A device which forms the sum of two or more numbers, or quantities, impressed on it. 2. In a color tv receiver, a circuit which amplifies the receiver primary signal coming from the matrix. Usually there is one adder circuit for each receiver primary channel.

addition record—A new record created during the processing of a file in a computer.

additive—Sometimes referred to as the key. A number, series of numbers, or alphabetical intervals added to a code to put it in a cipher.

additive color—A system which combines two colored lights to form a third.

additive primaries—Primary colors which can be mixed to form other colors, but which cannot themselves be produced by mixing other primaries. Red, green, and blue are the primaries in television because, when added in various proportions, they produce a wide range of other colors. For this reason, red, green, and blue are called additive primaries.

additron—An electrostatically focused, beam-switching tube used as a binary adder in high-speed digital computers.

address—1. An expression, usually numerical, which designates a specific location in a storage or memory device or other source or destination of information in a computer. 2. An identification, as represented by a name, label, or number, for a register, location in storage, or any other data source or destination such as the location of a station in a communications network. 3. Loosely, any part of an instruction that specifies the location of an operand for the instruction. 4. *Also see* Instruction Code.

address computation—The process by which the address part of an instruction in a digital computer is produced or modified.

addressed memory—In a computer, memory sections containing each individual register.

address modification—In a computer, a change in the address portion of an instruction or command such that, if the routine which contains that instruction or command is repeated, the computer will go to a new address or location for data or instructions.

address part—In an electronic-computer instruction, a portion of an expression designating location. (*Also see* Instruction Code.)

add-subtract time—The time required by a digital computer to perform addition or subtraction. It does not include the time required to obtain the quantities from storage and put the result back into storage.

add time—The time required in a digital computer to perform addition. It does not include the time required to obtain the quantities from storage and put the result back into storage.

ADF—*See* Automatic Direction Finder.

adiabatic damping—A reduction in the size of an accelerator beam as the energy of the beam is increased.

adiabatic demagnetization—A technique used to obtain temperatures within thousandths of a degree of absolute zero. It consists of applying a magnetic field to a substance at a low temperature and in good thermal contact with its surroundings, insulating the substance thermally, and then removing the magnetic field.

A-display—Also called A-scan. A radar scope presentation in which time (distance or range) is one co-ordinate (usually horizontal) and the target appears displaced perpendicular to the time base.

adjacent- and alternate-channel selectivity—A measure of the ability of a receiver to differentiate between a desired signal and between signals which differ in frequency from the desired signal by the width of one channel or two channels, respectively.

adjacent audio (sound) channel—The r-f carrier frequency which contains the sound modulation associated with the next lower-frequency television channel.

adjacent channel—That frequency band immediately above or below the one being considered.

adjacent-channel attenuation—*See* Selectance.

adjacent-channel interference—Undesired signals received on one communication channel from a transmitter operating on a channel immediately above or below.

adjacent-channel selectivity—The ability of a receiver to reject signals on channels adjacent to the channel of the desired station.

adjacent video carrier—The r-f carrier that carries the picture modulation for the television channel immediately above the channel to which the receiver is tuned.

adjustable resistor—A resistor which has the resistance wire partly exposed to enable the amount of resistance in use to be adjusted occasionally by the user. Adjustment requires the loosening of a screw, the subsequent moving of the lug, and retightening of the screw.

adjustable voltage divider—A wirewound resistor with one or more movable terminals that can be slid along the length of the exposed resistance wire until the desired voltage values are obtained.

adjusted circuit—Also called bolted-fault level. In a circuit the current measured under short-circuit conditions with the leads that are normally connected to the circuit breaker bolted together.

adjusted decibels—The noise level in a transmission system at any point in the system above a reference noise, when the noise meter used has been adjusted to represent the interfering effect under specified conditions. Abbreviated dba.

admittance—The ease with which an alternating current flows in a circuit. The reciprocal of impedance and usually expressed in mhos. Symbol is Y or y.

ADP—Abbreviation for automatic data processing.

adsorption—The deposition of a thin layer of gas or vapor particles or gas onto the surface of a solid. The process is known as chemisorption if the deposited material is bound to the surface by a simple chemical bond.

advance ball—In mechanical recording, a rounded support (often sapphire) which is attached to a cutter and rides on the surface of the recording medium. Its purpose is to maintain a uniform mean depth of cut and to correct for small irregularities on the surface of the disc.

advance wire—An alloy of copper and nickel, used in the manufacture of electric heating units and some wirewound resistors.

aeolight—A glow lamp which employs a cold cathode and a mixture of inert gases and in which the intensity of illumination varies with the applied signal voltage. This lamp is used to produce a modulated light for motion-picture sound recordings.

aerial—*See* Antenna.

aerial cable—A cable installed on a pole line or similar overhead structure.

aerodiscone antenna—An aircraft antenna that is aerodynamically shaped and is physically small compared to other antennas having similar electrical characteristics. Its radiation pattern is omnidirectional and linearly polarized.

aerodrome control radio station—A radio station providing communications between an aerodrome control tower and aircraft or mobile aeronautical radio station.

aerodynamics—The science of the motion of air and other gases. Also, the forces acting on bodies when they move through such gases, or when such gases move against or around the bodies.

aeromagnetic—Pertaining to the magnetic field of the earth as surveyed from the air.

aeronautical advisory station—A station used for civil defense and advisory communications with private aircraft stations.

aeronautical broadcasting service—The broadcasting service intended for the transmission of information related to air navigation.

aeronautical broadcast station—A radio station which broadcasts meteorological information and notices to airmen.

aeronautical fixed service—A fixed service intended for the transmission of information relating to air navigation and preparation for and safety of flight.

aeronautical fixed station—A station operating in the aeronautical fixed service.

aeronautical ground station—A radio station operated for the purpose of providing air-to-ground communications in connection with the operation of aircraft.

aeronautical marker-beacon station—A land station operating in the aeronautical radionavigation service and providing a signal to designate a small area above the station.

aeronautical mobile service—A radio service between aircraft and land stations or between aircraft stations.

aeronautical radio beacon station—A radionavigation land station in the aeronautical radionavigation service, the emission of which enables an aircraft or other mobile service to determine its bearing or its position in relation to the aeronautical radio beacon station.

aeronautical radionavigation service—A radionavigation service intended for use in the operation of aircraft.

aeronautical radio service—1. Service carried on between aircraft stations and/or land stations. 2. Special radio for air navigation.

aeronautical station—A land station (or in certain instances a shipboard station) in the aeronautical mobile service that carries on communications with aircraft stations.

aeronautical telecommunication agency—An agency to which is assigned the responsibility for operating a station or stations in the aeronautical telecommunication service.

aeronautical telecommunication log—A record of the activities of an aeronautical telecommunication station.

aeronautical telecommunications—Any telegraph or telephone communications of sign signals, writing, images, and sounds of any nature, by wire, radio or other system or process of signaling, used in the aeronautical service.

aeronautical telecommunication service—Telecommunication service provided for aeronautical purposes.

aeronautical telecommunication station—A station in the aeronautical telecommunication service.

aeronautical utility land station—A land station located at an airport control tower and used for communications connected with the control of ground vehicles and aircraft on the ground.

aeronautical utility mobile station—A mobile station used at an airport for communications with aeronautical utility land stations, ground vehicles, and aircraft on the ground.

aerophare—*See* Radio Beacon.

AES—Abbreviation for Audio Engineering Society.

af—*See* Audio Frequency.

afc—*See* Automatic Frequency Control.

afterglow—Also called phosphorescence. The light that remains in a gas-discharge tube after the voltage has been removed, or on the phosphorescent screen of a cathode-ray tube after the exciting electron beam has been removed.

afterheat—The heat produced by the continuing decay of radioactive atoms in a reactor after fission has stopped. Most of the afterheat is due to the radioactive decay of fission products.

afterpulse—In a photomultiplier, a spurious pulse induced by a preceding pulse.

agc—*See* Automatic Gain Control.

aging—1. Storing a permanent magnet, capacitor, rectifier, meter, or other device, sometimes with voltage applied, until its desired characteristics become essentially constant. 2. The change of a component or a material with time under defined environmental conditions, leading to improvement or deterioration of properties.

agonic line—An imaginary line on the earth's surface, all points of which have zero magnetic declination.

AGREE—Advisory Group on Reliability of Electronics Equipment.

aided tracking—A system of tracking a target signal in bearing, elevation, or range (or any combination of these variables) in which manual correction of the tracking error automatically corrects the rate at which the tracking mechanism moves.

AIEE—Abbreviation for American Institute of Electrical Engineers. Now merged with IRE to form IEEE.

airborne intercept radar—Short-range airborne radar employed by fighter and interceptor planes to track down their targets.

airborne noise—Undesired sound in the form of fluctuations of air pressure about the atmospheric pressure as a mean.

air capacitor—A capacitor in which air is the only dielectric material between its plates.

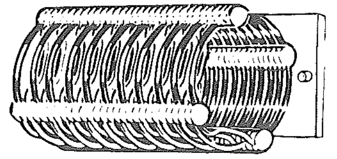
aircarrier aircraft station—A radio station aboard an aircraft that is engaged in or essential to the transportation of passengers or cargo for hire.

air cell—A cell in which depolarization at the positive electrode is accomplished chemically by reduction of the oxygen in the air.

air column—The air space within a horn or acoustic chamber.

air condenser—*See* Air Capacitor.

air-cooled tube—An electron tube in which the generated heat is dissipated to the surrounding air directly, through metal heat-radiating fins, or with the aid of channels or chimneys that increase the air flow.



Air-core coil.

air-core coil—A number of turns of spiral wire in which no metal is used in the center.

air-core transformer—A transformer (usually rf) having two or more coils wound around a nonmetallic core. Transformers wound around a solid insulating substance or on an insulating coil form are included in this category.

aircraft bonding—Electrically connecting together all of the metal structure of the aircraft, including the engine and metal covering of the wiring.

aircraft flutter—Flickering in a tv picture as the signal is reflected from flying aircraft. The reflected signal arrives in or out of phase with the normal signal and thus strengthens or weakens the latter.

aircraft station—A radio station installed on aircraft and continuously subject to human control.

airdrome control station—A station used for communication between an airport control tower and aircraft.

air gap—1. A nonmagnetic discontinuity in a ferromagnetic circuit. For example, the space between the poles of a magnet—although filled with brass, wood or any other nonmagnetic material—is nevertheless called an air gap. This gap reduces the tendency toward saturation. 2. The air space between two magnetically or electrically related objects.

air lock—A small chamber, located at the entrance to an area, the doors of which are so interlocked that only one can be opened at a time. This acts as an air seal to maintain the condition of the air within the area.

airport runway beacon—A radio-range beacon which defines one or more approaches to an airport.

airport surveillance radar — Radar equipment or a radar system used in air-traffic control. Used in conjunction with precision approach radar to scan the airspace for a distance of approximately thirty to sixty miles around an airport. It shows, on an indicator in the airport control tower, the location of all airborne aircraft below a certain altitude, as well as obstructions to flight within its range.

air-position indicator—Airborne computing system which presents a continuous indication of aircraft position on the basis of aircraft heading, air speed, and elapsed time.

air-spaced coax—A coaxial cable in which air is basically the dielectric material. The conductor may be centered by means of a spirally wound synthetic filament, by beads, or by braided filaments. This construction is also referred to as an air dielectric.

air-to-ground communication — Transmission of radio signals from an aircraft to stations or other locations on the earth's surface, as differentiated from ground-to-air, air-to-air, or ground-to-ground.

air-to-ground radio frequency—The frequency or band of frequencies agreed upon for transmission from an aircraft to an aeronautical ground station.

air-to-surface missile—A missile designed to be dropped from an aircraft. An internal homing device or the aircraft's radio guides it to a surface target.

airwaves—Slang expression for radio waves used in radio and television broadcasting.

alacritized switch—A mercury switch treated to yield a low adhesional force between the rolling surface and mercury pool, resulting in a decreased differential angle.

alarm relay—A relay, other than an annunciator, used to operate, or to operate in connection with, a visual or audible alarm.

albedo—The reflecting ability of an object. It is the ratio of the amount of light reflected compared to the amount received.

Alexanderson alternator—An early mechanical generator used as a source of low-frequency power for transmission or induction heating. It is capable of generating frequencies as high as 200,000 hertz.

algebraic adder—A computer circuit which can form an algebraic sum.

algol—An international problem language designed for the concise, efficient expression of arithmetic and logical processes and the control (iterative, etc.) of these processes. From ALGOrithmic Language.

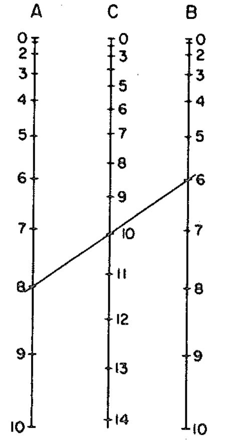
algorithm—A fixed step-by-step procedure for finding a solution to a problem.

align—To adjust the tuned circuits of a receiver or transmitter for maximum signal response.

aligned-grid tube—A multigrid vacuum tube in which at least two of the grids are aligned one behind the other to give such effects as beam formation and noise suppression.

alignment—The process of adjusting components of a system for proper interrelationship. The term is applied especially to (1) the adjustment of tuned circuits in a receiver to obtain the desired frequency response, and (2) the synchronization of components in a system.

alignment chart—Also called nomograph or abac. Chart or diagram consisting of two or more lines on which equations can be solved graphically. This is done by laying a straightedge on the two known values and reading the answer at the point where the straightedge intersects the scale for the value sought.



Alignment chart.

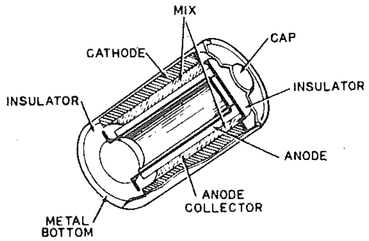
alignment pin—1. A pin in the center of the base of a tube. A projecting rib on the pin assures that the tube is correctly inserted into its socket. 2. Any pin or device that will insure the correct mating of two components designed to be connected.

alignment tool—A special screwdriver or socket wrench used for adjusting trimmer or padder capacitors or cores in tuning inductances. It is usually constructed partly or entirely of nonmagnetic material. (*Also see* Neutralizing Tool.)

alive—Electrically connected to a source of potential difference, or electrically charged to have a potential different from that of the earth.

alive circuit—One which is energized.

alkali—A compound which forms hydroxyl ions when in aqueous solution. Also called a base.



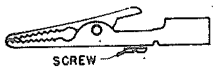
Alkaline cell.

alkaline cell—Also called alkaline-manganese. A primary cell similar to the zinc-carbon cell except that a potassium hydroxide (KOH) electrolyte is used. This cell has about 50 to 100 percent more capacity than the zinc-carbon cell. Nominal cell voltage is 1.5 volts.

all-diffused monolithic integrated circuit—Also called compatible monolithic integrated circuit. A microcircuit consisting of a silicon substrate into which all of the circuit parts (both active and passive elements) are fabricated by diffusion and related processes.

allen screw—A screw having a hexagonal hole or socket in its head. Often used as a setscrew.

allen wrench—A straight or bent hexagonal rod used to turn an Allen screw.



Alligator clip.

alligator clip—A spring-loaded metal clip with long, narrow meshing jaws, used for making temporary electrical connections.

allocate—In a computer, to assign storage locations to main routines and subroutines, thus fixing the absolute values of symbolic addresses.

allocated channels—A channel assigned to a specific user.

allocated frequency band—A segment of the radio-frequency spectrum established by competent authority designating the use which may be made of the frequencies contained therein.

allocated-use circuit—1. A circuit in which one or more channels have been allocated for the exclusive use of one or more services by a proprietary service; may be a unilateral or joint circuit. 2. Communication link specifically assigned to user(s) warranting such facilities.

alloy—A composition of two or more elements, of which at least one is a metal. It may be either a solid solution, a heterogeneous mixture, or a combination of both.

alloy deposition—The process of depositing an alloy on a substrate.

alloy-diffused transistor—A transistor with a diffused base and alloyed emitter.

alloyed contact—An ohmic contact formed by an alloy process.

alloy junction—Also called fused junction. A junction produced by alloying one or more impurity metals to a semiconductor. A small button of impurity metal is placed at each desired location on the semiconductor wafer, heated to its melting point, and cooled rapidly. The impurity metal alloys with the semiconductor material to form a P or N region, depending on the impurity used.

alloy-junction photocell—A photodiode in which an alloy junction is produced by alloying (mixing) an indium disc with a thin wafer of N-type germanium.

alloy-junction transistor—Also called fused-junction transistor. A semiconductor wafer of P- or N-type material with two dots containing P- or N-type impurities fused, or alloyed, into opposite sides of the wafer to provide emitter and base junctions. The base region comprises the original semiconductor wafer.

alloy process—A fabrication technique in which a small part of the semiconductor material is melted together with the desired metal and allowed to recrystallize. The alloy developed is usually intended to form a p-n junction or an ohmic contact.

alloy transistor—A transistor in which the emitter and collector junctions are both alloy junctions.

all-pass network—A network designed to introduce phase shift or delay but not appreciable attenuation at any frequency.

all-wave antenna—A receiving antenna suitable for use over a wide range of frequencies.

all-wave receiver—A receiver capable of receiving stations on all the commonly used wavelengths in short-wave bands as well as in the broadcast band.

alnico—An alloy consisting mainly of ALuminum, NIckel, and CObalt plus iron. Capable of very high flux density and magnetic retentivity. Used in permanent magnets for speakers, magnetrons, etc.

alpha—Emitter-to-collector current gain of a transistor connected as a common-base amplifier. For a junction transistor, alpha is less than unity, or 1.

alphabetic coding—A system of abbreviation used in preparing information for input into a computer. Information may then be reported in the form of letters and words as well as in numbers.

alphabetic-numeric—Having to do with the alphabetic letters, numerical digits, and special characters used in electronic data processing work.

alpha cutoff frequency—The frequency at which the current gain of a common-base transistor stage has decreased to 0.707 of its low-frequency value. Gives a rough indication of the useful frequency range of the device.

alphameric (alphanumeric)—Generic term for alphabetic letters, numerical digits, and special characters which are machine-processable.

alphanumeric—Pertaining to a character set that contains both letters and numerals and usually other characters.

alphanumeric code—A code used to express numerically the letters of the alphabet.

alpha particle—A small, electrically charged particle thrown off at a very high velocity by many radioactive materials including uranium and radium. Identical to the nucleus of a helium atom, it is made up of two neutrons and two protons. Its electrical charge is positive and is equal in magnitude to twice that of an electron.

alpha ray—A stream of fast-moving alpha particles which produce intense ionization in gases through which they pass, are easily absorbed by matter, and produce a glow on a fluorescent screen. The lowest-frequency radioactive emissions.

alternate channel—A channel located two channels above or below the reference channel.

alternate-channel interference — Interference caused in one communication channel by a transmitter operating in the channel after an adjacent channel. (*Also see* Second-Channel Interference.)

alternate frequency—The frequency assigned for use at a certain time, or for a certain purpose, to replace or supplement the frequency normally used.

alternate mode—A means of displaying on an oscilloscope the output signals of two or more channels by switching the channels, in sequence, after each sweep.

alternate routine—A secondary or backup communications path to be used if the normal (primary) routing is not possible.

alternating-charge characteristic — The function relating, under steady-state conditions, the instantaneous values of the alternating component of transferred charge to the corresponding instantaneous values of a specified periodic voltage applied to a nonlinear capacitor.

alternating current—Abbreviated ac. A flow of electricity which reaches maximum in one direction, decreases to zero, then reverses itself and reaches maximum in the opposite direction. The cycle is repeated continuously. The number of such cycles per second is the frequency. The average value of voltage during any cycle is zero.

alternating current/direct current — A term applied to electronic equipment indicating it is capable of operation from either an alternating-current or direct-current primary power source.

alternating-current erasing head—An erasing head, used in magnetic recording in which alternating current produces the magnetic field necessary for erasing. Alternating-current erasing is achieved by subjecting the medium to a number of cycles of a magnetic field of a decreasing magnitude. The medium is, therefore, essentially magnetically neutralized.

alternating-current pulse — An alternating-current wave of brief duration.

alternating-current transmission—In television, that form of transmission in which a fixed setting of the controls makes any instantaneous value of signal correspond to the same value of brightness only for a short time.

alternating quantity—A periodic quantity which has alternately positive and negative values, the average value of which is zero over a complete cycle.

alternating voltage—Also called a-c voltage. Voltage that is continually varying in value and reversing its direction at regular intervals, such as that generated by an alternator or developed across a resistance or impedance through which alternating current is flowing.

alternation—One-half of a cycle—either when an alternating current goes positive and returns to zero, or when it goes negative and returns to zero. Two alternations make one cycle.

alternator—A device for converting mechanical energy into electrical energy in the form of an alternating current.

alternator transmitter—A radio transmitter that generates power by means of a radio-frequency alternator.

altimeter—An instrument that indicates the altitude of an aircraft above a specific reference level, usually sea level or the ground below the aircraft. It may be similar to an aneroid barometer that utilizes the change of atmospheric pressure with altitude, or it may be electronic.

altimeter station—An airborne transmitter, the emissions from which are used to determine the altitude of an aircraft above the surface of the earth.

altitude—The vertical distance of an aircraft or other object above a given reference plane such as the ground or sea level.

altitude delay—The synchronization delay introduced between the line of transmission of the radar pulse and the start of the trace on the indicator. This is done to eliminate the altitude circle on the plan-position indicator-type display.

alto-troposphere—A portion of the atmosphere about 40 to 60 miles above the surface of the earth.

alumina—A ceramic used for insulators in electron tubes for substrates in thin-film circuits. It can withstand continuously high temperatures and has a low dielectric loss over a wide frequency range.

aluminized-screen picture tube—A cathode-ray picture tube which has a thin layer of aluminum deposited on the back of its fluorescent surface to improve the brilliance of the image and also prevent ion-spot formation.

aluminum-electrolytic capacitor—A capacitor with two aluminum electrodes (the anode has the oxide film) separated by layers of absorbent paper saturated with the operating electrolyte. The aluminum-oxide film or dielectric is repairable in the presence of an operating electrolyte.

am—*See* Amplitude Modulation.

amateur—Also called a ham. A person licensed to operate radio transmitters as a hobby. Any amateur radio operator.

amateur bands—Certain radio frequencies assigned exclusively to radio amateurs. In the United States of America, the Federal Communications Commission (FCC) makes these assignments.

amateur station—A radio transmitting station operated by one or more licensed amateur operators.

amateur-station call letters—A group of numbers and letters assigned exclusively to a licensed amateur operator to identify his station.

ambient—Surrounding. (*Also see* Ambient Noise; Ambient Temperature.)

ambient level—The level of interference emanating from sources other than the test sample, such as inherent noise of the measuring device and extraneous radiated fields.

ambient light—Normal room light.

ambient-light filter—A filter used in front of a television picture-tube screen to reduce the amount of ambient light reaching the screen, and to minimize reflections of light from the glass face of the tube.

ambient noise—Acoustic noise in a room or other location. Usually measured with a sound-level meter. The term "room noise" commonly designates ambient noise at a telephone station.

ambient pressure—The general surrounding atmospheric pressure.

ambient temperature—Temperature of air or liquid surrounding any electrical part or device. Usually refers to the effect of such temperature in aiding or retarding removal of heat by radiation and convection from the part or device in question.

ambient temperature range—The range of environmental temperatures in the vicinity of the unit, over which the unit may be operated safely and within specifications. For forced-air cooled units, the ambient temperature is measured at the air intake.

ambiguity—1. An undesirable tendency of a synchro or servo system to seek a false null position, in addition to the proper null position. 2. Inherent error resulting from multiple-bit changes in a polystrophic code. (Proper logic design prevents such errors.)

ambiguous count—A count on an electronic scaler that is obviously impossible.

American Institute of Electrical Engineers (AIEE) — Now merged with IRE to form IEEE.

American Morse code—A system of dot-and-dash signals originated by Samuel F. B. Morse and still used to a limited extent for wire telegraphy in North America. It differs from the International Morse code used in radiotelegraph transmission.

American Radio Relay League (ARRL)—An organization of amateur radio operators.

American Standards Association (ASA)—A national federation of 123 trade associations, technical and professional societies, and consumer groups whose purpose is to develop uniform and voluntary standards of performance, dimension, and terminology.

American wire gage (AWG)—The system of notation generally adopted in the United States for measuring the size of solid wires.

a-m/f-m receiver—A device capable of converting either amplitude- or frequency-modulated signals into audio frequencies.

a-m/f-m tuner—A device capable of converting either amplitude- or frequency- modulated signals into low-level audio frequencies.

ammeter — An instrument for measuring either direct or alternating electric current (depending on its construction). Its scale is usually graduated in amperes, milliamperes, microamperes, or kiloamperes.

ammeter shunt—A low-resistance conductor placed in parallel with the meter movement so most of the current flows through this conductor and only a small part passes through the movement itself. This extends the usable range of the meter.

amp—Abbreviation for ampere.

ampacity—Current-carrying capacity expressed in amperes.

amperage—The number of amperes flowing in an electrical conductor or circuit.

ampere—1. A unit of electrical current or rate of flow of electrons. One volt across 1 ohm of resistance causes a current flow of 1 ampere. A flow of 1 coulomb per second equals 1 ampere. An unvarying current is passed through a solution of silver nitrate of standard concentration at a fixed temperature. A current that deposits silver at the rate of .001118 gram per second is equal to 1 ampere, or 6.25×10^{18} electrons per second passing a given point in a circuit. 2. The constant current which, if maintained in two straight parallel conductors of infinite length, of negligible circular sections, and placed 1 meter apart in a vacuum will produce between these conductors a force equal to 2×10^{-7} newton per meter of length.

ampere-hour—A current of one ampere flowing for one hour. Multiplying the current in amperes by the time of flow in hours gives the total number of ampere-hours. Used mostly to indicate the amount of energy a storage battery can deliver before it needs recharging, or the energy a primary battery can deliver before it needs replacing. One ampere-hour equals 3,600 coulombs.

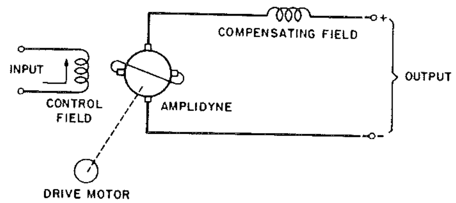
ampere-hour capacity—The amount of current a battery can deliver in a specified length of time under specified conditions.

ampere-hour meter—An electrical meter which measures the amount of current (amperes) per unit of time (hours) which has been consumed in a circuit.

Ampere's rule—Current in a certain direction is equivalent to the motion of positive charges in that direction. The magnetic flux generated by a current in a wire encircles the current in the counter clockwise direction when the current is approaching the observer.

ampere-turn—The magnetomotive force produced by a coil, derived by multiplying the number of turns of wire in the coil by the current (in amperes) flowing through it.

amp-hr—Abbreviation for ampere-hour or ampere-hours.



Amplidyne.

amplidyne—A special direct-current generator used extensively in servo systems as a power amplifier. The response of its output voltage to changes in field excitation is very rapid, and its amplification factor is high.

amplification—Increase in size of a medium in its transmission from one point to another. May be expressed as a ratio or, by extension of the term, in decibels.

amplification factor (μ)—1. In a vacuum tube, the ratio of a small change in plate voltage to a small change in grid voltage required to produce the same change in plate current (all other electrode voltages and currents being held constant). 2. In any device, the ratio of output magnitude to input magnitude.

amplified agc—An automatic gain-control circuit in which the control voltage is amplified before being applied to the tube or transistor, the gain of which is to be controlled in accordance with the strength of the incoming signal.

amplified back bias—Degenerative voltage developed across a fast time-constant circuit within a stage of an amplifier and fed back into a preceding stage.

amplifier—A device which draws power from a source other than the input signal and which produces as an output an enlarged reproduction of the essential features of its input. The amplifying element may be an electron tube, transistor, magnetic circuit, or any of various devices.

amplifier noise—All spurious or unwanted signals, random or otherwise, that can be observed in a completely isolated amplifier in the absence of a genuine input signal.

amplifier nonlinearity—The inability of an amplifier to produce an output at all times proportionate to its input.

amplify—To increase in magnitude or strength, usually said of a current or voltage.

amplistat—A self-saturating type of magnetic amplifier.

Amplitron—A broad-band crossed-field amplifier with a re-entrant electron stream. The electron stream interacts with the backward wave of a nonre-entrant r-f structure. (Raytheon.)

amplitude—The magnitude of variation in a changing quantity from its zero value. The word must be modified with an adjective such as peak, rms, maximum, etc., which designates the specific amplitude in question.

amplitude-controlled rectifier—A rectifier circuit in which a thyratron is the rectifying element.

amplitude distortion—In an amplifier or other device, that which occurs when the output amplitude is not a linear function of the input amplitude. (Note: Amplitude distortion is measured with the system operating under steady-state conditions and with a sinusoidal input signal. When other frequencies are present, the term "amplitude" applies to the fundamental only.)

amplitude fading—Fading in which the amplitudes of all frequency components of a modulated carrier wave are uniformly attenuated.

amplitude-frequency response—The variation of gain, loss, amplification, or attenuation of a device or system as a function of frequency. Usually measured in the region where the transfer characteristic is essentially linear.

amplitude gate—*See* Slicer.

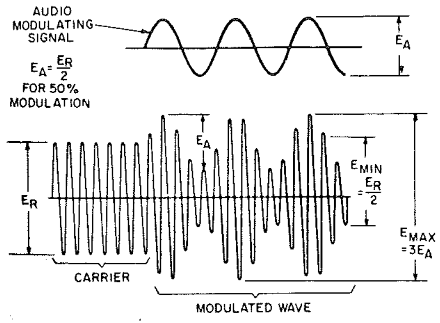
amplitude-level selection—The choice of the voltage level at which an oscilloscope sweep is triggered.

amplitude limiter—A circuit or stage which automatically reduces the amplification to prevent signal peaks from exceeding a predetermined level.

amplitude-modulated transmitter—A transmitter in which the amplitude of its radio-frequency wave is varied at a low frequency rate—usually in the audio or video range. This low frequency is the intelligence (information) to be conveyed.

amplitude-modulated wave—A constant-frequency waveform in which the amplitude varies in step with the frequency of an impressed signal.

amplitude modulation—1. Modulation in which the amplitude of a wave is the characteristic subject to variation. 2. Those systems of modulation in which each component frequency (f) of the transmitted intelligence produces a pair of sideband frequencies at carrier frequency plus (f) and carrier frequency minus (f). 3. In special cases, the carrier may be suppressed; either the lower or upper sets of sideband frequencies may be suppressed; the lower set of sideband frequencies may be produced by one or more channels of information. The carrier may be transmitted without intelligence-carrying sideband frequencies. The resulting emission bandwidth is proportional to the highest frequency component of the intelligence transmitted.



Amplitude modulation.

amplitude-modulation noise level—Undesired amplitude variations of a constant radio-frequency signal, especially in the absence of any intended modulation.

amplitude noise—The effect on radar accuracy of the fluctuations in amplitude of the signal returned by the target. These fluctuations are caused by any change in aspect if the target is not a point source.

amplitude of noise—When impulse-type noise is of random occurrence and so closely spaced that the individual wave shapes are not separated by the receiving equipment, then the noise has the waveshape and characteristics of random noise. Random-noise amplitude is proportional to the square root of the bandwidth. If the impulses are separated, the noise no longer has the wave shape of random noise and its amplitude is directly proportional to the bandwidth of the transmission system.

amplitude permeability—The relative permeability at a stated value of field strength and under stated conditions, the field strength varying periodically with time and no direct magnetic-field component being present.

amplitude range—The ratio, usually expressed in decibels, between the upper and lower limits of program amplitudes which contain all significant energy contributions.

amplitude resonance—The condition that exists when any change in the period or frequency of the periodic agency (but not its amplitude) decreases the amplitude of the oscillation or vibration of the system.

amplitude selection—The process of selecting that portion of a waveform which lies above or below a given value, or between two given values.

amplitude separator—A television-receiver circuit that separates the control impulses from the video signal.

amplitude-suppression ratio—In frequency modulation, the ratio of the magnitude of the undesired output to the magnitude of the desired output of an f-m receiver when the applied signal is simultaneously amplitude- and frequency-modulated. Generally measured with an applied signal that is amplitude-modulated 30% at a 400-hertz rate and is frequency-modulated 30% of the maximum system deviation at a 1,000-hertz rate.

amplitude versus frequency distortion—Distortion caused by the nonuniform attenuation or gain of the system, with respect to frequency under specified terminal conditions.

a-m tuner—A device capable of converting amplitude-modulated signals into low-level audio frequencies.

amu—Abbreviation for atomic mass unit.

anacoustic zone—Zone of silence in space where distances between air molecules are so great that sound waves are not propagated.

analog—In electronic computers a physical system in which the performance of measurements yields information concerning a class of mathematical problems.

analog channel—A computer channel in which the transmitted information can have any value between the defined limits of the channel.

analog communications—A system of telecommunications employing a nominally continuous electrical signal that varies in frequency, amplitude, etc., in some direct correlation to nonelectrical information (sound, light, etc.) impressed on a transducer.

analog computer—A computer operating on the principle of creating a physical (often electrical) analogy of the mathematical problem to be solved. Variables such as temperature or flow are represented by the magnitude of a physical phenomenon such as voltage or current. The computer manipulates these variables in accordance with the mathematical formulas "analogued" on it.

analog data—A physical representation of information such that the representation bears an exact relationship to the original information. The electrical signals on a telephone channel are an analog data representation of the original voice. 2. Data represented in a continuous form, as contrasted with digital data represented in a discrete (discontinued) form. Analog data are usually represented by physical variables, such as voltage, resistance, rotation, etc.

analog network—A circuit or circuits that represent physical variables in such a manner as to permit the expression and solution of mathematical relationships between the variables, or to permit the solution directly by electric or electronic means.

analog output—As distinguished from digital output. Here the amplitude is continuously proportionate to the stimulus, the proportionality being limited by the resolution of the device.

analog recording—A method of recording in which some characteristic of the record current, such as amplitude or frequency, is continuously varied in a manner analogous to the time variations of the original signal.

analog representation — A representation that does not have discrete values, but is continuously variable.

analog switch—A device that either transmits an analog signal without distortion, or completely blocks it.

analog-to-digital converter—A device which produces a digital output from an input in the form of physical motion or electrical voltages.

Analytical Engine—An early form of general-purpose digital computer invented in 1833 by Charges Babbage.

analyzer—1. An instrument or other device designed to examine the functions of components, circuits, or systems, and their relations to each other, as contrasted with an instrument designed to measure some specific parameter of such a system or circuit. 2. Of computers, a routine the purpose of which is to analyze a program written for the same or a different computer. This analysis may consist of summarizing instruction references to storage and tracing sequences of jumps.

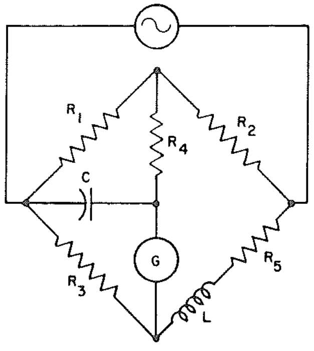
anastigmat—A lens system designed so as to be free from the aberration called astigmatism.

anchor—An object, such as a metal rod, set into the ground to hold the end of a guy wire.

ancillary equipment — Equipment not directly employed in the operation of a system, but necessary for logistic support, preparation of flight or assessment of target damage —e.g. test equipment, vehicle transport.

AND circuit—Synonym for AND gate.

Anderson bridge—A bridge normally used for the comparison of self-inductance with capacitance. It is a 6-branch network in which an outer loop of four arms is formed by four nonreactive resistors and the unknown inductor. An inner loop of three arms is formed by a capacitor and a fifth resistor in series with each other and in parallel with the arm opposite the unknown inductor. The detector is connected between the junction of the capacitor and the fifth resistor and at that end of the unknown inductor separated from a terminal of the capacitor by only one resistor. The source is connected to the other end of the unknown inductor and to the junction of the capacitor with two resistors of the outer loop. The balance is independent of frequency.



Anderson bridge.

AND gate—In an electronic computer, a gate circuit with more than one control (input) terminal. No output signal will be produced unless a pulse is applied to all inputs simultaneously.

anechoic enclosure—A term originally applied to audio-frequency low-reflection enclosures. Now applied generally to low-reflection enclosures.

anechoic room—An enclosure in which reflected sound energy is negligible. Used for measurement of microphone and speaker characteristics.

anemometer—An instrument used for measuring the force or speed of wind.

angels — Short-duration radar reflections in the lower atmosphere. Most often caused by birds, insects, organic particles, tropospheric layers, or water vapor.

angle—1. A fundamental mathematical concept formed when two straight lines meet at a point. The lines are the sides of the angle, and the point of intersection is the vertex. 2. A measure of the distance along a wave or part of a cycle, measured in degrees. 3. The distance through which a rotating vector has progressed.

angle modulation—Modulation in which the angle of a sine-wave carrier is the characteristic varied from its normal value. Phase and frequency modulation are particular forms of angle modulation.

angle noise—Tracking error introduced into radar by variations in the apparent angle of arrival of the echo from a target due to finite target size. (This effect is caused by variations in the phase front of the radiation from a multiple-point target as the target changes its aspect with respect to the observer.)

angle of advance—*See* Braid Angle.

angle of arrival—Angle made between the line of propagation of a radio wave and the earth's surface at the receiving antenna.

angle of azimuth—The angle measured clockwise in a horizontal plane, usually from the north. The north used may be true north, Y-north, or magnetic north.

angle of beam—The angle which encloses most of the transmitted energy from a directional-antenna system.

angle of convergence—Angle formed by the lines of sight of both eyes when focusing on an object.

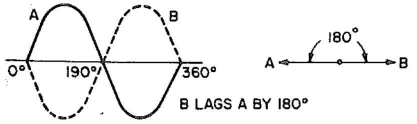
angle of deflection—The angle formed between the new position of the electron beam in a cathode-ray tube and the normal position before deflection.

angle of departure—The angle of the line of propagation of a radio wave with respect to a horizontal plane at the transmitting antenna.

angle of divergence—In cathode-ray tubes, a measure of its spread as the electron beam travels from the cathode to the screen. The angle formed by an imaginary center line and the border line of the electron beam. In good tubes, this angle is less than 2°.

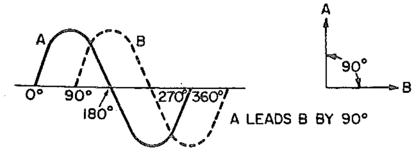
angle of elevation—The angle between the horizontal plane and the line ascending to the object.

angle of incidence—The angle between a wave or beam striking a surface and a line perpendicular to that surface.



Angle of lag.

angle of lag—The angular phase difference between one sinusoidal function and a second having the same frequency. Expressed in degrees, the amount the second function must be retarded to coincide with the first.



Angle of lead.

angle of lead—1. The time or angle by which one alternating electrical quantity leads another of the same cyclic period. 2. The angle through which the commutator brushes of a generator or motor must be moved from the normal position to prevent sparking.

angle of radiation—The angle between the surface of the earth and the center of the beam of energy radiated upward into the sky from a transmitting antenna.

angle of reflection—The angle between a wave or beam leaving a surface and a line perpendicular to that surface.

angle of refraction—The angle between a wave or beam as it passes through a medium and a line perpendicular to the surface of that medium.

angle tracking noise—Any deviation of the tracking axis from the center of reflectivity of a target. The resultant of servonoise, receiver noise, angle noise, and amplitude noise.

angstrom unit—A unit of measurement of a wavelength of light and other radiation. Equal to one ten-thousandth of a micron or one hundred-millionth of a centimeter (10^{-8} cm). The visible spectrum extends from about 4,000 to 8,000 angstrom units. Blue light has a wavelength in the region of 4,700 angstroms; yellow, 5,800; and red, 6,500.

angular acceleration — The time rate of change in angular velocity.

angular accelerometer—A device capable of measuring the magnitude of, and/or variations in, angular acceleration.

angular aperture—The largest angular extent of wave surface which an objective can transmit.

angular deviation loss—The ratio of the response of a microphone or speaker on its principal axis to the response at a specified angle from the principal axis (expressed in decibels).

angular distance—The angle subtended by two bodies at the point of observation. It is equal to the distance in wavelengths multiplied by 2π radians or by 360°.

angular frequency—Frequency expressed in radians per second. It is equal to the number of hertz (cycles per second) multiplied by 2π.

angular length—Length expressed in radians or equivalent angular measure equal to 2π radians, or 360°, multiplied by the length in wavelengths.

angular phase difference — Phase difference between two sinusoidal functions expressed as an angle.

angular rate—The rate of change of bearing.

angular velocity—The rate at which an angle changes. Expressed in radians per second, the angular velocity of a periodic quantity is the frequency multiplied by 2π. If the periodic quantity results from uniform rotation of a vector, the angular velocity is the number of radians per second passed over by the rotating vector. Generally designated by the Greek letter omega (ω).

anhysteresis—The process whereby a material is magnetized by applying a unidirectional field upon which is superimposed an alternating field of gradually decreasing amplitude.

anion—A negatively charged ion which, during electrolysis, is attracted toward the anode. A corresponding positive ion is called the cation.

anisotropic—A material that has better magnetic characteristics along one axis than any other.

anisotropic body—A body in which the value of any given property depends on the direction of measurement, as opposed to a body that is isotropic.

anisotropic magnet—A magnetic material having a better magnetic characteristic along the preferred axis than along any other.

anisotropy—Directional dependence of magnetic properties, leading to the existence of easy or preferred directions of magnetization. Anisotropy of a particle may be related to its shape, to its crystalline structure, or to the existence of strains within it.

annealed wire—A wire which has been softened by heating (soft-drawn wire).

annealing—The process of heating any solid material such as glass or metal, followed by slow cooling. This generally lowers the tensile strength and thereby improves the ductility.

annular—Ringed; ring-shaped.

annular transistor—A mesa transistor in which the semiconductor regions are arranged in concentric circles about the emitter.

annulling network—An arrangement of impedance elements connected in parallel with filters to annul or cancel capacitive or inductive impedance at the extremes of the passband of a filter.

annunciation relay—1. An electromagnetically operated signaling apparatus which indicates whether a current is flowing or has flowed in one or more circuits. 2. A nonautomatic reset device which gives a number of separate visual indications upon the functioning of protective devices, and which may also be arranged to perform a lockout function.

annunciator—A visual device consisting of a number of pilot lights or drops. Each light or drop indicates the condition which exists or has existed in an associated circuit and is labeled accordingly.

anode—1. The positive electrode such as the plate of a vacuum tube; the element to which the principal stream of electrons flows. 2. In a cathode-ray tube, the electrodes connected to a source of positive potential. These anodes are used to concentrate and accelerate the electron beam for focusing. 3. The less noble and/or higher-potential electrode of an electrolytic cell at which corrosion occurs. This may be an area on the surface of a metal or alloy, the more active metal in a cell composed of two dissimilar metals, or the positive electrode of an impressed-current system.

anode-balancing coil—A set of mutually coupled windings used to maintain approximately equal currents in anodes operating in parallel from the same transformer terminal.

anode breakdown voltage—The potential required to cause conduction across the main gap of a gas tube when the starter gap is not conducting and all other tube elements are held at cathode potential.

anode-bypass capacitor—Also called plate-bypass capacitor. A capacitor connected between the anode and ground in an electron tube circuit. Its purpose is to bypass high-frequency currents and keep them out of the load.

anode characteristic—A graph that shows how the anode current of an electron tube is affected by changes in the anode voltage.

anode circuit breaker—A device used in the anode circuits of a power rectifier for the primary purpose of interrupting the rectifier circuit if an arc-back should occur.

anode current—The electron flow in the element designated as the anode. Usually signifies plate current.

anode dark space—In a gas tube, a narrow, dark zone next to the surface of the anode.

anode dissipation—The power dissipated as heat in the anode of an electron tube because of the bombardment by electrons and ions.

anode efficiency—*See* Plate Efficiency.

anode-load impedance—*See* Plate-Load Impedance.

anode modulation—*See* Plate Modulation.

anode neutralization—Also called plate neutralization. A method of neutralization in which a portion of the anode-cathode a-c voltage is shifted 180° and applied to the grid-cathode circuit through a neutralizing capacitor.

anode power input—*See* Plate Power Input.

anode power supply—The means for supplying power to the plate of an electron tube at a more positive voltage than that of the cathode. (*Also see* Plate Power Supply.)

anode pulse modulation—*See* Plate Pulse Modulation.

anode rays—Positive ions coming from the anode of an electron tube; these ions are generally due to impurities in the metal of the anode.

anode saturation—*See* Plate Saturation.

anode sheath—A layer of electrons surrounding the anode in mercury-pool arc tubes.

anode strap—A metallic connector between selected anode segments of a multicavity magnetron, used principally for mode separation.

anode supply—Also called plate supply. The direct-voltage sources used in an electron-tube circuit to place the anode at a high positive potential with respect to the cathode.

anode terminal—The semiconductor-diode terminal that is positive with respect to the other terminal when the diode is biased in the forward direction.

anode voltage—The potential difference existing between the anode and cathode.

anode voltage drop (of a glow-discharge, cold-cathode tube)—Difference in potential between cathode and anode during conduction, caused by the electron flow through the tube resistance (IR drop).

anodizing—An electrochemical oxidation process used to improve the corrosion resistance or to enhance the appearance of a metal surface. Aluminum and magnesium parts are frequently anodized.

anomalous propagation—1. Propagation that is unusual or abnormal. 2. The conduction of uhf signals through atmospheric ducts or layers in a manner similar to that of a waveguide. These atmospheric ducts carry the signals with less than normal attenuation over distances far beyond the optical path taken by uhf signals. Also called superrefraction. 3. In sonar, pronounced and rapid variations in the strength of the echo due to large, rapid focal fluctuations in propagation conditions.

A – N radio range—A navigational aid which provides four equisignal zones for aircraft guidance. Deviation from the assigned course is indicated aurally by the Morse code letters A (• —) or N (— •). On-course position is indicated by an audible merging of the A and N code signals into a continuous tone.

A – N signal—A radio-range, quadrant-designation signal which indicates to the pilot whether he is on course or to the right or left.

answerback—The response of a terminal to remote-control signals. *Also see* Handshaking.

antenna—Also called aerial. That portion, usually wires or rods, of a radio transmitter or receiver station used for radiating waves into or receiving them from space.

antenna array—A system of two or more antennas coupled together to obtain desirable directional effects.

antenna bandwidth—The range of frequencies over which the impedance characteristics of the antenna are sufficiently uniform that the quality of the radiated signal is not significantly impaired.

antenna beam width—The angle, in degrees, between two opposite half-power points of an antenna beam.

antenna coil—In a radio receiver or transmitter, the inductance through which antenna current flows.

antenna coincidence—That instance when two rotating, highly directional antennas are pointed toward each other.

antenna-conducted interference—Any signal that is generated within a transmitter or receiver, and appears as an undesired signal at the antenna terminals of the device—e.g., harmonics of a transmitter signal, or the local-oscillator signal of the receiver.

antenna cores—Ferrite cores of various cross-sections for use in radio antennas.

antenna coupler—1. A radio-frequency transformer used to connect an antenna to a transmission line or to connect a transmission line to a radio receiver. 2. A radio-frequency transformer, link circuit, or tuned line used to transfer radio-frequency energy from the final plate-tank circuit of a transmitter to the transmission line feeding the antenna.

antenna cross talk—A measure of undesired power transfer through space from one antenna to another. Usually expressed in decibels, the ratio of power received by one antenna to the power transmitted by the other.

antenna current—The radio-frequency current that flows in an antenna.

antenna detector—A device consisting of an antenna and electronic equipment to warn aircraft crew members of their being observed by radar sets. (Usually located in the nose or tail of the aircraft and illuminates a light on one or more panels when radar signals are detected.)

antenna-directivity diagram—A curve representing, in polar or Cartesian coordinates, a quantity proportional to the gain of an antenna in the various directions in a particular plane or cone.

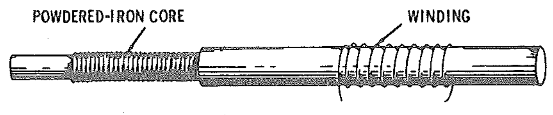
antenna disconnect switch—A safety switch or interlock plug used to remove driving power from the antenna to prevent rotation while work is being performed.

antenna duplexer—A circuit that permits two transmitters to transmit simultaneously from the same antenna without interaction between them.

antenna effect—1. Cause of error in a loop antenna due to the capacitance to ground. 2. In a navigational system, any undesirable output signal that results when a directional antenna acts as a nondirectional antenna.

antenna effective area—In any specified direction, the square of the wavelength multiplied by the power gain (or directive gain) in that direction, and divided by 4π. (When power gain is used, the effective area is that for power reception; when directive gain is used, the effective area is that for directivity.)

antenna factor—The value in db that must be added to a two-terminal voltmeter reading to obtain the actual induced antenna open-circuit voltage or the electric-field strength.



Antenna core.

antenna field—1. The region defined by a group of antennas. 2. A group of antennas placed in a geometric configuration which is specific for a particular trajectory measuring system. 3. The effective free-space energy distribution produced by an antenna or group of antennas.

antennafier—An integrated low-profile antenna and amplifier for use with compact, portable communications systems.

antenna gain—The effectiveness of a directional antenna in a particular direction, compared against a standard (usually an isotropic antenna). The ratio of standard antenna power to the directional antenna power that will produce the same field strength in the desired direction.

antenna ground system—That portion of an antenna closely associated with the earth and including an extensive conducting surface which may be the earth itself.

antenna height—The average antenna height above the terrain from two to ten miles from the antenna. In general, the antenna height will be different in each direction from the antenna. The average of these various heights is considered the antenna height above average terrain.

antenna-induced microvolts—The voltage that exists across the open-circuited antenna terminals, as calculated from a measurement.

antenna lens—An arrangement of metal vanes or dielectric material used to focus a microwave beam in a manner similar to an optical lens.

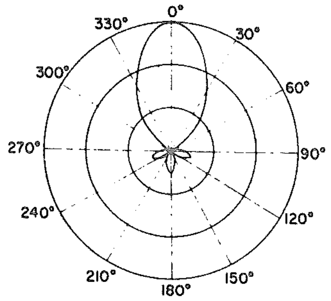
antenna lobe—*See* Lobe.

antenna matching—Selection of components to make the impedance of an antenna equal to the characteristic impedance of its transmission line.

antennamitter—An integrated low-profile antenna and oscillator for use with compact, portable communications systems.

antenna pair—Two antennas located on a base line of accurately surveyed length. The signals received by these antennas are used to determine quantities related to a target position.

antenna pattern—Also called antenna polar diagram. A plot of angle *versus* free-space field intensity at a fixed distance in the horizontal plane passing through the center of the antenna.



Antenna pattern.

antenna-pattern measuring equipment—Devices used to measure the relative field strength or intensity existing at any point or points in the space immediately surrounding an antenna.

antenna pedestal—A structure which supports an antenna assembly (motors, gears, synchros, rotating joints, etc.).

antenna polar diagram—*See* Antenna Pattern.

antenna power—The square of the antenna current of a transmitter, multiplied by the antenna resistance at the point where the current is measured.

antenna power gain—The power gain of an antenna in a given direction is four times the ratio of the radiation intensity in that direction to the total power delivered to the antenna. (The term is also applied to receiving antennas.)

antenna reflector—In a directional-antenna array, an element which modifies the field pattern in order to reduce the field intensity behind the array and increase it in front. In a receiving antenna, the reflector reduces interference from stations behind the antenna.

antenna relay—A relay used in radio stations to automatically switch the antenna to the receiver or transmitter and thus protect the receiver circuits from the r-f power of the transmitter.

antenna resistance—The total resistance of a transmitting antenna system at the operating frequency. The power supplied to the entire antenna circuit, divided by the square of the effective antenna current referred to the feed point. Antenna resistance is made up of such components as radiation resistance, ground resistance, radio-frequency resistance of conductors in the antenna circuit, and equivalent resistance due to corona, eddy currents, insulator leakage, and dielectric power loss.

antenna resonant frequency—The frequency (or frequencies) at which an antenna appears to be a pure resistance.

antenna stabilization—A system for holding a radar beam steady despite the roll and pitch of a ship or airplane.

antenna switch—Switch used for connecting an antenna to or disconnecting it from a circuit.

antenna system—An assembly consisting of the antenna and the necessary electrical and mechanical devices for insulating, supporting, and/or rotating it.

antenna terminals—On an antenna, the points to which the lead-in (transmission line) is attached.

antenna tilt error—The angular difference between the antenna tilt angle shown on the mechanical indicator, and the electrical center of the radar beam.

antenna wire—A wire, usually of high tensile strength such as copperweld, bronze, etc., with or without insulation, used as an antenna for radio and electronic equipment.

antiaircraft missile—A guided missile launched from the surface against an airborne target.

anticapacitance switch—A switch with widely separated legs, designed to keep capacitance at a minimum in the circuits being switched.

anticathode—Also called target. The target of an X-ray tube on which the stream of electrons from the cathode is focused and from which the X rays are radiated.

anticlutter circuit—In a radar receiver, an auxiliary circuit which reduces undesired reflection, to permit the detection of targets which otherwise would be obscured by such reflections.

anticlutter gain control—A device which automatically and gradually increases the gain of a radar receiver from low to maximum within a specified period after each transmitter pulse. In this way, short-range echoes producing clutter are amplified less than long-range echoes.

anticoincidence—A nonsimultaneous occurrence of two or more events (usually, ionizing events).

anticoincidence circuit—A counter circuit that produces an output pulse when either of two input circuits receives a pulse, but not when the two inputs receive pulses simultaneously.

anticollision radar—A radar system used in an aircraft or ship to warn of possible collision.

antiferroelectricity—The property of a class of crystals which also undergo phase transitions from a higher to a lower symmetry. They differ from the ferroelectrics in having no electric dipole moment.

antiferroelectric materials—Those materials in which spontaneous electric polarization occurs in lines of ions; adjacent lines are polarized in an antiparallel arrangement.

antiferromagnetic materials—Those materials in which spontaneous magnetic polarization occurs in equivalent sublattices; the polarization in one sublattice is aligned antiparallel to the other.

antiferromagnetic resonance—The absorption of energy from an oscillating electromagnetic field by a system of processing spins located on two sublattices, with the spins on one sublattice going in one direction and the spins on the other sublattice in the opposite direction.

antihunt—A stabilizing signal or equalizing circuit used in a closed-loop feedback system of a servomechanism to prevent the system from hunting, or oscillating. Special types of antihunt circuits are the anticipator, derivative, velocity feedback, and damper.

antihunt circuit—A circuit used to prevent excessive correction in a control system.

antihunt device—A device used in positioning systems to prevent hunting or oscillation of the load around an ordered position. The device may be mechanical or electrical. It usually involves some form of feedback.

antijamming—1. Art of minimizing the effect of enemy electronic countermeasures to permit echoes from targets detected by radar to be visible on the indicator. 2. Controls or circuit features incorporated to minimize jamming.

antijamming radar data processing—Use of data from one or more radar sources to determine target range in the presence of jamming.

antilogarithm—The number from which a given logarithm is derived. For example, the logarithm of 4261 is 3.6295. Therefore the antilogarithm of 3.6295 is 4261.

antimagnetic—Made of alloys that will not remain in a magnetized state.

antimicrophonic—Specifically designed to prevent microphonics. Possessing the characteristic of not introducing undesirable noise or howling into a system.

antimissile missile—A missile which is launched to intercept and destroy another missile in flight.

antinodes—Also called loops. The points of maximum displacement in a series of standing waves. Two similar and equal wave trains traveling at the same velocity in opposite directions along a straight line result in alternate antinodes and nodes along the line. Antinodes are separated from their adjacent nodes by half the wavelength of the wave motion.

antinoise carrier-operated device—A device commonly used to mute the audio output of a receiver during standby or no carrier periods. Usually the automatic volume control voltage is used to control a squelch tube which, in turn, controls the bias applied to the first audio tube so that it is permitted to operate only when a carrier is present at the receiver input. Thus, the receiver output is heard when a signal is received, and is muted when no signal is present.

antinoise microphone—A microphone which discriminates against acoustic noise. A lip or throat microphone is an example.

antiproton—An elementary atomic particle which has the same mass as a proton but is negatively charged.

antiresonant circuit—A parallel-resonant circuit offering maximum impedance to the series passage of the resonant frequency.

antiresonant frequency—1. The frequency at which the impedance of a system is very high. 2. Of a crystal unit, the frequency for a particular mode of vibration at which, neglecting dissipation, the effective impedance of the crystal unit is infinite.

antiresonant frequency of a crystal unit—For a particular mode of vibration, the frequency at which (neglecting dissipation) the effective impedance of the crystal unit is infinite.

antisidetone—In a telephone circuit, special circuits and equipment which are so arranged that only a negligible amount of the power generated in the transmitter reaches the associated receiver.

antisidetone circuit—A telephone circuit which prevents sound, introduced in the local transmitter, from being reproduced in the local receiver. (Reduces sidetones.)

antisidetone induction coil—An induction coil designed for use in an antisidetone telephone set.

antisidetone telephone set—A telephone set with an antisidetone circuit.

antistickoff voltage—A small voltage, usually applied to the rotor winding of the coarse synchro control transformer in a two-speed system. The antistickoff voltage acts to eliminate the possibility of ambiguous behavior in the system.

antitransmit-receive switch—Abbreviated ATR switch. An automatic device employed in a radar system to prevent received energy from being absorbed in the transmitter.

aperiodic—Having no fixed resonant frequency or repetitive characteristics or no tendency to vibrate. A circuit that will not resonate within its tuning range is often called aperiodic.

aperiodic antenna—An antenna designed to have a constant impedance over a wide frequency range (for example, a terminated rhombic antenna).

aperiodic damping—Also called overdamping. The condition of a system when the amount of damping is so large that, when the system is subjected to a single disturbance, either constant or instantaneous, the system comes to a position of rest without passing through that position. While an aperiodically damped system is not strictly an oscillating system, it has such properties that it should become an oscillating system if the damping is sufficiently reduced.

aperiodic function—A function having no repetitive characteristics.

aperture—1. In a unidirectional antenna, that portion of the plane surface which is perpendicular to the direction of maximum radiation and through which the major part of the radiation passes. 2. In an opaque disc, the hole or window placed on either side of a lens to control the amount of light passing through. 3. Also called aperture time. The amount of uncertainty about the exact time when the encoder input was at the value represented by a given output code. In general, the aperture is equal to the conversion time; it may be reduced by the use of sample-and-hold circuits.

aperture compensation—Reduction of aperture distortion by boosting the high-frequency response of a television-camera video amplifier.

aperture distortion—In a television signal, the distortion due to the finite dimension of the camera-tube scanning beam. The beam covers several mosaic globules simultaneously, resulting in a loss of picture detail.

aperture illumination—The field distribution in amplitude and phase through the aperture.

aperture mask—Also called shadow mask. A thin sheet of perforated material placed directly behind the viewing screen in a three-gun color picture tube to prevent the excitation of any one color phosphor by either of the two electron beams not associated with that color.

aperture plate—A ferrite memory plate containing a large number of uniformly spaced holes arranged in parallel rows and interconnected by plated conductors to provide a magnetic memory plane.

A power supply—A power supply used as a source of heating current for the cathode or filament of a vacuum tube.

apparent bearing—The direction from which the signal arrives with respect to some reference direction.

apparent power—The product of voltage and current of a single-phase circuit in which the two reach their peaks at different times.

apparent source—*See* Effective Acoustic Center.

Applegate diagram—A graphical representation of electron bunching in a velocity-modulated tube, showing their positions along the drift space. This bunching is plotted on the vertical coordinate, against time along the horizontal axis.

Appleton layer—In the ionosphere, a region of highly ionized air capable of reflecting or refracting radio waves back to earth. It is made up of the F_1 and F_2 layers.

appliance—Any electrical equipment used in the home and capable of being operated by a nontechnical person. Included are units that perform some task that could be accomplished by other, more difficult means, but usually not those used for entertainment (radios, tv's, hi-fi sets, etc.).

application factor—A modifier of the failure rate. It is based on deviations from rated operating stress (usually temperature and one electrical parameter).

applicator (applicator electrodes)—Appropriately shaped conducting surfaces between which an alternating electric field is established for the purpose of producing dielectric heating.

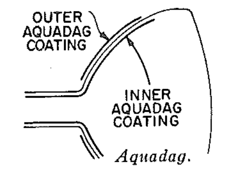
applied voltage—The potential between a terminal and a reference point in any circuit or device.

applique circuit—A special circuit provided to modify existing equipment in order to allow for some special usage.

approach-control radar—Any radar set or system used in a ground-controlled approach system—e.g., an airport-surveillance radar, precision approach radar, etc.

approach path—In radio aircraft navigation, that portion of the flight path in the immediate vicinity of a landing area where such flight path terminates at the touchdown point.

AQL—Abbreviation for acceptable quality level.



Aquadag.

aquadag—A conductive graphite coating on the inner side walls of some cathode-ray tubes. It serves as an electrostatic shield or as a postdeflection and an accelerating anode. Also applied to outer walls and grounded; here it serves, with the inner coating, as a capacitor to filter the applied high voltage.

arbitrary function fitter—A circuit having an output voltage or current that is a presettable, adjustable, usually nonlinear function of the input voltage(s) or current(s) fed to it.

arc—1. A luminous discharge of electricity through a gas. Characterized by a change in space potential in the immediate vicinity of the cathode; this change is approximately equal to the ionization potential of the gas. 2. A prolonged electrical discharge, or series of prolonged discharges, between two electrodes. (Both produce a bright-colored flame, as contrasted to a dim corona-glow discharge).

arcback—Also called backfire. Failure of the rectifying action in a tube, resulting from the flow of a principal electron stream in the reverse direction due to the formation of a cathode spot on the anode. This action limits the peak inverse voltage which may be applied to a particular rectifier tube.

arc converter—A form of oscillator utilizing an electric arc to generate an alternating or pulsating current.

arc discharge—A discharge between electrodes in gas or vapor. Characterized by a relatively low voltage drop and a high current density.

arc drop—The voltage drop between the anode and cathode of a gas rectifier tube during conduction.

arc-drop loss—In a gas tube, the product of the instantaneous values of arc-drop voltage and current averaged over a complete cycle of operation.

arc-drop voltage—The voltage drop between the anode and cathode of a gas rectifier tube during conduction.

arc failure—1. A flashover in the air near an insulation surface. 2. An electrical failure in the surface heated by a flashover arc. 3. An electrical failure in the surface damaged by the flashover arc.

arc furnace—An electric furnace heated by arcs between two or more electrodes.

arcing—The production of an arc—for example, at the brushes of a motor or at the contact of a switch.

arcing contacts—Special contacts on which the arc is drawn after the main contacts of a switch or circuit breaker have opened.

arcing time—1. The interval between the parting, in a switch or circuit breaker, of the arcing contacts and the extension of the arc. 2. The time elapsing, in a fuse, from the severance of the fuse link to the final interruption of the circuit under the specified condition.

arc lamp—Application of an electric arc to produce a brilliant light. Used extensively in spotlights and motion-picture projectors.

arc oscillator—A negative-resistance oscillator comprised of a sustained d-c arc and a resonant circuit.

arcover voltage—Under specified conditions, the minimum voltage required to create an arc between electrodes separated by a gas or liquid insulation.

arc percussive welding—A type of welding in which the materials to be welded are separated by a gap, across which an arc is struck; the arc melts the surfaces of the materials, and the materials are simultaneously brought together. *See also* Pulse Arc Welding.

arc resistance—The length of time that a material can resist the formation of a conductive path by an arc adjacent to the surface of the material. Also called tracking resistance.

arc suppressor—*See* Spark Suppressor.

arc-through—A loss of control in multielectrode gas tubes. As a result, the principal electron stream flows during a scheduled nonconducting period.

area redistribution—A method of measuring the duration of irregularly shaped pulses. A rectangle is drawn having the same peak amplitude and the same area as the original pulse under consideration. Because the same time units are used in measuring the original and the new pulse, the width of the rectangle is considered the duration of the pulse.

argon—An inert gas used in discharge tubes and some electric lamps. It gives off a purple glow when ionized.

argon glow lamp—A glow lamp containing argon gas which produces a pale blue violet light.

argument—The independent variable of a function.

arithmetic check—A check of a computation making use of the arithmetical properties of the computation.

arithmetic element—Synonym for arithmetic unit.

arithmetic mean—Usually, the same as average. It is obtained by first adding quantities together and then dividing by the number of quantities involved. It also means a figure midway between two extremes and is found by adding the minimum and maximum together and dividing by two.

arithmetic operation—In an electronic computer, the operations in which numerical quantities form the elements of the calculation, including the fundamental operations of arithmetic (addition, subtraction, multiplication, comparison, and division).

arithmetic organ—*See* Arithmetic Unit.

arithmetic shift—In a digital computer, the multiplication or division of a quantity by a power of the base used in the notation.

arithmetic unit—Also called arithmetic element or arithmetic organ. In an automatic digital computer, that portion in which arithmetical and logical operations are performed on elements of information.

armature—The moving element in an electromechanical device such as the rotating part of a generator or motor, the movable part of a relay, or the spring-mounted, iron portion of a bell or buzzer.

armature contacts—1. Contacts mounted directly on the armature. 2. Sometimes used for movable contacts.

armature core—An assembly of laminations forming the magnetic circuit of an armature.

armature gap—The space between the armature and pole face.

armature hesitation—A delay or momentary reversal of the motion of the armature.

armature-hesitation contact chatter—Chatter caused by delay or momentary reversal in direction of the armature motion of a relay during either the operate or the release stroke.

armature-impact contact chatter—Chatter caused by impact of the armature of a relay on the pole piece in operation, or on the backstop in release.

armature overtravel—That portion of the available stroke occurring after the contacts of a relay have touched.

armature reaction—In an armature, the reaction of the magnetic field produced by the current on the magnetic lines of force produced by the field coil of an electric motor or generator.

armature rebound — Return motion of the armature of a relay after it strikes the backstop.

armature-rebound contact chatter—Chatter caused by the partial return of the armature of a relay to its operated position as a result of rebound from the backstop in release.

armature relay—A relay operated by an electromagnet which, when energized, causes an armature to be attracted to a fixed pole or poles.

armature slot—In the core of an armature, a slot or groove into which the coils or windings are placed.

armature stud — In a relay, an insulating member that transmits the motion of the armature to an adjacent contact member.

armature travel—The distance traveled during operation by a specified point on the armature of a relay.

armature voltage control—A means of controlling the speed of a motor by changing the voltage applied to its armature windings.

armature wire—Stranded annealed copper wire, straight lay, soft loose white cotton braid. It is used for low-voltage, high-current rotor winding motors and generators. Straight lay permits forming in armature slots, and compressibility.

armchair copy—Amateur term for clear, static-free signals.

armed sweep—*See* Single Sweep.

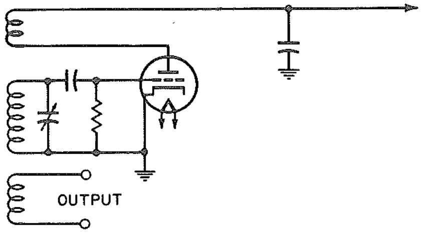
arming the oscilloscope sweep—Closing a switch which enables the oscilloscope to trigger on the next pulse.

armor—A metallic cover placed over the insulation of wire or cable to protect it from abrasion or crushing.

armored cable—Two or more insulated wires collectively provided with a metallic covering, primarily to protect the insulated wires from damage.

armor clamp—A fitting for gripping the armor of a cable at the point where the armor terminates or where the cable enters a junction box.

Armstrong frequency-modulation system—A phase-shift modulation system originally proposed by E. H. Armstrong.



Armstrong oscillator.

Armstrong oscillator—An inductive feedback oscillator that consists of a tuned grid circuit and an untuned tickler coil in the plate circuit. Feedback is controlled by varying the coupling between the tickler and the grid circuit.

array—In an antenna, a group of elements arranged to provide the desired directional characteristics. These elements may be antennas, reflectors, directors, etc.

array antenna—An antenna comprising a number of radiating elements, generally similar, arranged and excited to obtain directional effects.

array device—A group of many similar, basic, complex, or integrated devices without separate enclosures. Each has at least one of its electrodes connected to a common conductor, or all are connected in series.

arrester—1. Also called a lightning arrester. A protective device used to provide a bypass path directly to ground for lightning discharges that strike an antenna or other conductor. 2. A power-line device capable of reducing the voltage of a surge applied to its terminals, interrupting current if present, and restoring itself to original operating conditions.

ARRL — Abbreviation for American Radio Relay League.

arrowhead—A linearly polarized, frequency-independent, log-periodic antenna.

ARSR—Abbreviation for Air Route Surveillance Radar.

articulation— (Sometimes called intelligibility.) In a communications system, the percentage of speech units understood by a listener. The word "articulation" is customarily used when the contextual relationships among the units of speech material are thought to play an unimportant role; the word "intelligibility," when the context is thought to play an important role in determining the listener's perception.

articulation equivalent—The articulation of speech reproduced over a complete telephone connection, expressed numerically in terms of the trunk loss of a working reference system which is adjusted to give equal articulation.

artificial antenna—Also called dummy antenna. A device which simulates a real antenna in its essential impedance characteristics and has the necessary power-handling capabilities, but which does not radiate or receive radio waves. Used mainly for testing and adjusting transmitters.

artificial ear—A microphone-equipped device for measuring the sound pressures developed by an earphone. To the earphone it presents an acoustic impedance equivalent to the impedance presented by the human ear.

artificial echo—1. Received reflections of a transmitted pulse from an artificial target, such as an echo box, corner reflector, or other metallic reflecting surface. 2. A delayed signal from a pulsed radio-frequency signal generator.

artificial horizon—A gyroscopically operated instrument that shows, within limited degrees, the pitching and banking of an aircraft with respect to the horizon. Lines or marks on the face of the instrument represent the aircraft and the horizon. The relative positions of the two are then easily discernible.

artificial ionization—Introduction of an artificial reflecting or scattering layer into the atmosphere to permit beyond-the-horizon communications.

artificial line—A lumped-constant network designed to simulate some or all the characteristics of a transmission line over a desired frequency range.

artificial line duct—A balancing network simulating the impedance of the real line and distant terminal apparatus. It is employed in a duplex circuit to make the receiving device unresponsive to outgoing signal currents.

artificial load—Also called dummy load. A dissipative but essentially nonradiating device having the impedance characteristics of an antenna, transmission line, or other practical utilization circuit.

artificial radioactivity — Radioactivity induced in stable elements under controlled conditions by bombarding them with neutrons or high-energy, charged particles. Artificially radioactive elements emit beta and/or gamma rays.

artificial voice—A small speaker mounted in a specially shaped baffle that is proportioned to simulate the acoustical constants of the human head. It is used for calibrating and testing close-talking microphones.

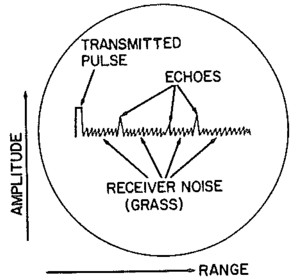
artos stripper—A machine which, when properly adjusted, will automatically measure to a predetermined length, cut, strip, count, and tie wire in bundles.

artwork—An accurately scaled configuration used to produce a master pattern.

ASA—Abbreviation for American Standards Association.

ASA code—A code recommended by the American Standards Association for industry-wide use in the transmission of information.

asbestos—A nonflammable material generally used for heat insulation, such as in a line-cord resistor.



A-scan.

A-scan—Also called A-display. On a cathode-ray indicator, a presentation in which time (range or distance) is one co-ordinate (horizontal) and signals appear as perpendicular deflections to the time scale (vertical).

A-scope—An oscilloscope that uses an A-scan to present the range of a target as the distance along a horizontal line from the transmitted pulse pip to the target, or echo pip. Signals appear as vertical excursions of the horizontal line, or trace.

aspect ratio—Ratio of frame width to frame height. In the United States the television standard is 4/3.

asperities—Local microscopic points on an electrode surface at which there is considerable field enhancement. They lead to a dependence of electric strength on electrode area (area effect).

aspheric—Not spherical; an optical element having one or more surfaces that are not spherical.

ASR—1. Abbreviation for airport surveillance radar. 2. Abbreviation for automatic send-receive set. A combination teletypewriter, transmitter, and receiver with transmission capability from either a keyboard or paper tape. Most often used in a half-duplex circuit.

ASRA — Abbreviation for automatic stereophonic recording amplifier. An instrument developed by Columbia Broadcasting System for stereo recording. Compression of the vertical component of the stereo recording signal is automatically decreased or increased as required by the recording conditions.

assemble—In digital computer programming, to put together subprograms into a complete program.

assembly—1. A complete operating unit, such as a radio receiver, made up of subassemblies such as an amplifier and various components. 2. Process in which instructions written in symbolic form by the programmer are changed to machine language by the computer.

assembly program — A computer program flexible enough to incorporate subroutines into the main program.

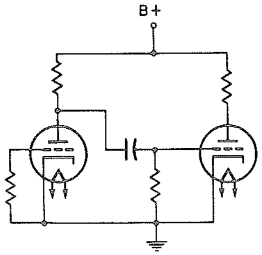
assignable cause—A definitely identified factor contributing to a quality variation.

assigned frequency—The center of the frequency band assigned to a station.

assigned frequency band—The frequency band, the center of which coincides with the frequency assigned to the station, and the width of which equals the necessary bandwidth plus twice the absolute value of the frequency tolerance.

astable circuit—A circuit which continuously alternates between its two unstable states at a frequency determined by the circuit constants. It can be readily synchronized by applying a repetitive input signal of slightly higher frequency. A blocking oscillator is an example of an astable circuit.

astable multivibrator (free-running)—A circuit having two momentarily stable states, between which it continuously alternates, remaining in each for a period controlled by the circuit parameters and switching rapidly from one to the other.



Astable multivibrator.

astatic—1. Having no particular orientation or directional characteristics; such as a vertical antenna. 2. Being in neutral equilibrium; having no tendency toward any change of position.

astatic galvanometer—A sensitive galvanometer used for detecting small currents. Consists of two small magnetized needles of equal size and strength arranged in parallel and with their north and south poles adjacent, suspended inside the galvanometer coil. Since the resultant magnetic moment is zero, the earth's magnetic field does not affect the system.

astigmatism—A type of spherical aberration in which the rays from a single point of an object do not converge on the image, thereby causing a blurred image. Astigmatism in an electron-beam tube is a focus defect in which electrons in different axial planes come to focus at different points.

astrionics—Electronics as involved with astronautics.

astrocompass—An instrument for determining direction relative to the stars. It is unaffected by the errors to which magnetic or gyrocompasses are subject.

astrodome—A rigid hemispherical structure used to cover large tracking instruments to protect them from the elements. It is usually constructed so that the dome rotates with the instrument.

astronautics—The science and art of operating space vehicles.

astrotracker—A device for tracking stars.

A-supply—The A-battery, transformer filament winding, or other voltage source that supplies power for heating the filaments of vacuum tubes.

asymmetrical cell—A cell, such as a photoelectric cell, in which the impedance to the flow of current is greater in one direction than in the other direction.

asymmetrical distortion—Distortion affecting a two-condition or binary modulation or restitution, in which all the significant intervals corresponding to one of the two significant conditions have longer or shorter durations than the corresponding theoretical durations of the excitation. If this particular requirement is not met, distortion is present.

asymmetric sideband transmission — *See* Vestigial Sideband Transmission.

asymmetry control—In pH meters, an adjustment sometimes provided to compensate for differences in the electrodes.

asymptote—A line which comes nearer and nearer a given curve but never touches it.

asymptotic breakdown voltage—A voltage that will break down insulation if applied over a long period of time.

asynchronous—Not having a constant period.

asynchronous computer—An automatic digital computer in which an operation is started by a signal denoting that the previous operation has been completed.

asynchronous device—A device in which the speed of operation is not related to any frequency in the system to which it is connected.

asynchronous machine — Any machine in which its speed of operation is not proportionate to the frequency of the system to which the machine is connected.

AT-cut crystal—A quartz-crystal slab cut at a 35° angle with respect to the optical, or Z-axis, of the crystal. It has practically a zero temperature coefficient and is used at frequencies of about 0.5 to 10 megahertz.

atmosphere—1. The body of air surrounding the earth. 2. A unit of pressure defined as the pressure of 760 mm of mercury at 0° C. Approximately 14.7 pounds per square inch.

atmospheric absorption—The energy lost in the transmission of radio waves due to dissipation in the atmosphere.

atmospheric absorption noise—The dominant noise factor, at frequencies above 1000 MHz, caused by the absorption of energy from radio waves by oxygen and water vapor in the atmosphere.

atmospheric duct—Within the troposphere, a condition in which the variation of refractive index is such that the propagation of an abnormally large proportion of any radiation of sufficiently high frequency is confined within the limits of a stratum. This effect is most noticeable above 3,000 MHz.

atmospheric electricity — Static electricity between clouds, or between clouds and the earth.

atmospheric noise—Also called atmospherics. The noise heard during radio reception because of atmospheric interference.

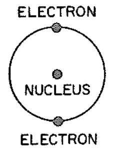
atmospheric pressure—The barometric pressure of air at a particular location on the earth's surface. The nominal, or standard, value of atmospheric pressure is 760 mm of mercury (14.7 pounds per square inch) at sea level. Atmospheric pressure decreases at higher altitudes.

atmospheric radio wave—A radio wave that is propagated by reflections in the atmosphere. May include the ionospheric wave, the tropospheric wave, or both.

atmospheric radio window—That portion of the frequency spectrum that will allow radio-frequency waves to pass through the earth's atmosphere (approximately 10 to 10,000 MHz).

atmospheric refraction — The bending of the path of electromagnetic radiation from a distant point as the radiation passes obliquely through varying air densities.

atmospherics—Also referred to as static, atmospheric noise, and strays. In a radio tuner or receiver, noise due to natural weather phenomena and electrical charges existing in the atmosphere.



Atom.

atom—The smallest portion of an element which exhibits all properties of the element. It is pictured as composed of a positively charged nucleus containing almost all the mass of the atom, surrounded by one or more electrons. In the neutral atom, the number of electrons is such that their total charge (negative) exactly equals the positive charge in the nucleus.

atomic battery—*See* Nuclear Battery.

atomic charge—The electronic charge of an ion, equal to the number of ionization multiplied by the charge on one electron.

atomic energy—*See* Nuclear Energy.

atomic fission—*See* Fission.

atomic frequency — The natural vibration frequency of an atom.

atomic fuel—A fissionable material—i.e., one in which the atomic nucleus may be split to release energy.

atomic fusion—*See* Fusion.

atomic mass unit—Abbreviated amu. Used to express the relative masses of isotopes. It is so proportioned that the mass of a neutral atom of the naturally most abundant isotope of oxygen (O16) is 16.00000 atomic mass units.

atomic migration—The progressive transfer of a valance electron from one atom to another within the same molecule.

atomic number—The number of protons (positively charged particles) in the nucleus of an atom. All elements have different atomic numbers, which determine their positions in the periodic table. For example, the atomic number of hydrogen is 1; that of oxygen is 8; iron, 26; lead, 82; uranium, 92.

atomic power—*See* Nuclear Energy.

atomic ratio—The ratio of quantities of different substances to the number of atoms of each.

atomic reactor—*See* Nuclear Reactor.

atomic theory—A generally accepted theory concerning the structure and composition of substances and compounds. It states that everything is composed of various combinations of ultimate particles called atoms.

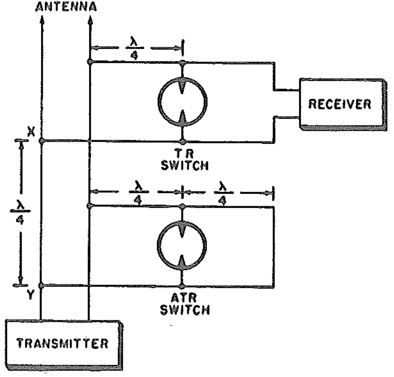
atomic weight—The approximate weight of the number of protons and neutrons in the nucleus of an atom. The atomic weight of oxygen, for example, is approximately 16 (actually it is 16.0044)—it contains 8 neutrons and 8 protons. Aluminum is 27 and contains 14 neutrons and 13 protons. If expressed in grams, these weights are called gram atomic weights.

ATR tube — Abbreviation for antitransmit-receive tube. A gas-filled, radio-frequency switching tube used to isolate the transmitter while a pulse is being received.

attachment cord—*See* Patch Cord.

attack—The length of time it takes for a tone in an organ to reach full intensity after a key is depressed. On most organs this effect is adjustable by either a switch or potentiometer.

attack time—The interval required for an



ATR (switch) tube.

input signal, after suddenly increasing in amplitude, to attain a specified percentage (usually 63%) of the ultimate change in amplification or attenuation due to this increase.

attenuating — Decreasing electrical current, voltage, or power in a communicating channel. Refers to audio, radio, or carrier frequencies.

attenuation—The decrease in amplitude of a signal during its transmission from one point to another. It may be expressed as a ratio or, by extension of the term, in decibels.

attenuation constant—1. The real component of the propagation constant. 2. For a traveling plane wave at a given frequency, the rate at which the amplitude of a field component (or the voltage or current) decreases exponentially in the direction of propagation, in nepers or decibels per unit length.

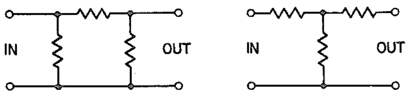
attenuation distortion—1. In a circuit or system, its departure from uniform amplification or attenuation over the frequency range required for transmission. 2. Distortion that causes a decrease in the amplitude of a field component (voltage or current) in the direction of propagation.

attenuation equalizer—A corrective network designed to make the absolute value of the transfer impedance of two chosen pairs of terminals substantially constant for all frequencies within a desired range.

attenuation-frequency distortion — A form of wave distortion in which the relative magnitudes of the different frequency components of the wave are changed.

attenuation network—1. A network providing relatively slight phase shift and substantially constant attenuation over a range of frequencies. 2. The arrangement of circuit elements, usually impedance elements, inserted in circuitry to introduce a known loss or to reduce the impedance level without reflections.

attenuation ratio — The magnitude of the propagation ratio which indicates the relative decrease in energy.



Attenuators.

attenuator—1. An adjustable resistive network for reducing the amplitude of an electrical signal without introducing appreciable phase or frequency distortion. 2. A distributed network that absorbs part of a signal and transmits the remainder with a minimum of distortion or delay.

attenuator tube—A gas-filled, radio-frequency switching tube in which a gas discharge, initiated and regulated independently from the radio-frequency power, is used to control this r-f power by reflection or absorption.

atto—Prefix meaning 10^{-18}. Abbreviated a.

audibility—1. The ability to be heard, usually construed as being heard by the human ear. 2. The ratio of the strength of a specific sound to the strength of a sound that can barely be heard. Usually expressed in decibels.

audible—Capable of being heard, in most contexts by the average human ear.

audible tones—Sounds composed of frequencies which the average human can detect.

audio—Pertaining to frequencies corresponding to a normally audible sound wave. These frequencies range roughly from 15 to 20,000 hertz.

audio amplifier — *See* Audio-Frequency Amplifier.

audio band—The range of audio frequencies passed by an amplifier, receiver, transmitter, etc. (*Also see* Audio Frequency.)

audio-channel wire—A small-diameter wire, shielded and jacketed, used primarily in radio and television for wiring consoles, panels, etc.

audio component—That portion of any wave or signal which contains frequencies in the audible range (between 15 and 20,000 hertz).

audio frequency—Abbreviated af. Any frequency corresponding to a normally audible sound wave. Audio frequencies range roughly from 15 to 20,000 hertz.

audio-frequency amplification—An increase in voltage, current, or power of a signal at the audio frequency.

audio-frequency amplifier—Also called audio amplifier. A device which contains one or more electron tubes or transistors (or both) and which is designed to amplify signals within a frequency range of about 20 to 20,000 hertz.

audio-frequency choke—An inductance used to impede the flow of audio-frequency currents.

audio-frequency noise — In the audio-frequency range, any electrical disturbance introduced from a source extraneous to the signal.

audio-frequency oscillator—An oscillator circuit using an electron tube, transistor, or other nonrotating device capable of producing audio signals.

audio-frequency peak limiter — A circuit generally used in the audio system of a radio transmitter to prevent overmodulation. It keeps the signal amplitude from exceeding a predetermined value.

audio-frequency shift modulator—A system of facsimile transmission over radio, in which the frequency shift required is applied through an 800-hertz shift of an audio signal, rather than shifting the transmitter frequency. The radio signal is modulated by the shifting audio signal, usually at 1500 to 2300 hertz.

audio-frequency transformer — Also called audio transformer. An iron-core transformer for use with audio-frequency currents to transfer signals from one circuit to another. Used for impedance matching or to permit maximum transfer of power.

audiogram—Also called threshold audiogram. A graph showing hearing loss, percent of hearing loss, or percent of hearing as a function of frequency.

audio-level meter—An instrument that measures audio-frequency power with reference to a predetermined level. Usually calibrated in decibels.

audiometer — An instrument for measuring hearing acuity. Measurements may be made with speech signals (usually recorded) or with tone signals.

audion—A three-electrode vacuum tube introduced by Dr. Lee de Forest.

audio oscillator—*See* Audio-Frequency Oscillator.

audio patch bay—Specific patch panels provided for termination of all audio circuits and equipment used in the channel and technical-control facility. This equipment can also be found in transmitting and receiving stations.

audio peak limiter — *See* Audio-Frequency Peak Limiter.

audiophile—A person who is interested in good musical reproduction for his own personal listening and who uses the latest audio equipment and techniques.

audio signal—An electrical signal the frequency of which is within the audio range.

audio spectrum—The continuous range of audio frequencies extending from the lowest to the highest (from about 15 to 20,000 hertz.

audio taper — Semilogarithmic change of resistance. Used on tone controls in audio amplifiers to compensate for the lower sensitivity of the human ear when listening to low-volume sounds.

audio transformer — *See* Audio-Frequency Transformer.

audiovisual—Involving both sight and sound. (As audiovisual education uses films, slides, phonograph records, and the like, to supplement instruction.)

audiovisual system—A system of communications which simultaneously transmits pictorial and audio signals.

augend—In an arithmetic addition, the number increased by having another number (called the addend) added to it.

augmented operation code—In a computer, an operation code that is further defined by information contained in another portion of an instruction.

aural—Pertaining to the ear or to the sense of hearing. (*Also see* Audio.)

aural radio range—A radio range the courses of which are normally followed by interpretation of an aural signal.

aural signal—The signal corresponding to the sound portion of a television program. In general, the audible component of a signal.

aural transmitter—The equipment used to transmit the aural (sound) signals from a television broadcast station.

aurora—Sheets, streamers, or streaks of pale light often seen in the skies of the northern and southern hemispheres. The aurora borealis and aurora australis.

auroral absorption — Absorption of radio waves due to auroral activity. (*Also see* Aurora.)

authorized carrier frequency — A specific carrier frequency authorized for use, from which the actual carrier frequency is permitted to deviate, solely because of frequency instability, by an amount not to exceed the frequency tolerance.

autoalarm—Also called automatic alarm receiver. A device which is tuned to the international distress frequency of 500 kHz and which automatically actuates an alarm if any signal is received.

auto call—An alerting device which sounds a preset code of signals in a building, to page those persons whose code is being sounded.

autodyne circuit—A vacuum-tube circuit which serves simultaneously as an oscillator and as a heterodyne detector.

autodyne reception—A type of radio reception employed in regenerative receivers for the reception of c-w code signals. In this system the incoming signal beats with the signal from an oscillating detector to produce an audible beat frequency.

auto-man—A locking switch which controls the method of operation—i.e., automatic or manual.

automata—A plural form of automaton.

automatic—Self-regulating or self-acting; capable of producing a desired response to certain predetermined conditions.

automatic-alarm receiver — Complete receiving, selecting, and warning device capable of being actuated automatically by intercepted radio-frequency signals forming the international automatic-alarm signal.

automatic back bias—A radar-receiver technique which consists of one or more automatic gain-control loops to prevent large signals from overloading a receiver, whether by jamming or by actual echoes.

automatic bass compensation—A circuit used in a receiver or audio amplifier to make the bass notes sound more natural at low volume settings. The circuit, which usually consists of resistors and capacitors connected to taps on the volume control, automatically compensates for the poor response of the human ear to weak sounds.

automatic bias—*See* Self-Bias.

automatic brightness control—A circuit used in television receivers to keep the average brightness of the reproduced image essentially constant. Its action is similar to that of an automatic volume-control circuit.

automatic check—An operation performed by equipment built into an electronic computer to automatically verify proper operation.

automatic chrominance control—A color-television circuit which automatically controls the gain of the chrominance bandpass amplifier by varying the bias.

automatic circuit breaker—A device that automatically opens a circuit, usually by electromagnetic means, when the current exceeds a safe value. Unlike a fuse, which must be replaced once it blows, the circuit breaker can be reset manually when the current is again within safe limits.

automatic coding—A technique by which a digital computer is programmed to perform a significant portion of the coding of a problem.

automatic color purifier—*See* Automatic Degausser.

automatic computer—A computer which automatically handles long sequences of reasonable operations without further intervention from a human being.

automatic contrast control—A television circuit which automatically changes the gain of the video i-f and r-f stages to maintain proper contrast in the television picture.

automatic crossover—A type of current-limiting circuit on a power supply provided with an adjustment for setting the short-circuit current to an adjustable maximum value.

automatic current limiting—An overload-protection mechanism designed to limit the maximum output current of a power supply to a preset value. Usually it automatically restores the output when the overload is removed.

automatic cutout—A device operated by electromagnetism or centrifugal force, to automatically disconnect some parts of an equipment after a predetermined operating limit has been reached.

automatic data processing—The processing of digital information by automatic computers and other machines. Abbreviated ADP. Also called integrated data processing.

automatic degausser—Also called automatic color purifier and degausser. An arrangement of degaussing coils mounted around a color-television picture tube. These coils are energized only for a short while after the set is turned on. They serve to demagnetize any parts of the picture tube that may have been affected by the earth's magnetic field or the magnetic field of any nearby home appliance.

automatic direction finder—Abbreviated ADF. Also called an automatic radio compass. An electronic device, usually for marine or aviation application, which provides a radio bearing to any transmitter whose frequency is known but whose direction and location are not.

automatic error correction—A technique, usually requiring the use of special codes and/or automatic retransmission, which detects and corrects errors occurring in transmission. The degree of correction depends upon coding and equipment configuration.

automatic exchange—A telephone exchange in which connections are made between subscribers by means of devices set in operation by the originating subscriber's instrument and without the intervention of an operator.

automatic focusing—A method of electrostatically focusing a television picture tube; the focusing anode is internally connected through a resistor to the cathode and thus requires no external focusing voltage.

automatic frequency control—Abbreviated afc. A circuit that automatically maintains the frequency of an oscillator within specified limits.

automatic gain control—1. Abbreviated agc. A type of circuit used to maintain the output volume of a receiver constant, regardless of variations in the signal strength applied to the receiver. 2. A self-acting compensation device which maintains the output of a transmission system constant within narrow limits in the face of wide variations in the attenuation of the system. 3. A radar circuit which prevents saturation of the radar receiver by long blocks of received signals, or by a carrier modulated at low frequency.

automatic gain stabilization—A circuit, used in certain identification friend-or-foe equipment and radar beacon systems, which serves to maintain optimum sensitivity in a superregenerative stage by keeping the noise-pulse load constant. The system prevents random noises from triggering the automatic transmitter associated with the receiver.

automatic grid bias—Grid-bias voltage provided by the difference in potential across a resistance (or resistances) in the grid or cathode circuit due to grid or cathode current or both.

automatic level compensation—A system which automatically compensates for variations in the circuit. *See also* Automatic Volume Control.

automatic light control—The process by

which the illumination incident upon the face of a television pickup device is automatically adjusted as a function of scene brightness.

automatic modulation control—A transmitter circuit that reduces the gain for excessively strong audio input signals without affecting the strength of normal signals, thus permitting higher average modulation without overmodulation; this is equivalent to an increase in the carrier-frequency power output.

automatic noise limiter—A vacuum-tube circuit that automatically clips off all noise peaks above the highest peak of the desired signal being received. This circuit prevents strong atmospheric or man-made interference from being troublesome.

automatic pedestal control—The process by which the pedestal height of a television signal is automatically adjusted as a function of the input or other specified parameter.

automatic phase control—A circuit used in color television receivers to synchronize the burst signal with the 3.58-MHz color oscillator.

automatic pilot—*See* Autopilot.

automatic programming—Any technique designed to simplify the writing and execution of programs in a computer. Examples are assembly programs which translate from the programmer's symbolic language to the machine language, those which assign absolute addresses to instruction and data words, and those which integrate subroutines into the main routine.

automatic radio compass—A radio direction finder which automatically rotates the loop antenna to the correct position. A bearing can then be secured from the indicator dials without mechanical adjustments or calculation. (*Also see* Automatic Direction Finder.)

automatic record changer—An electrically operated mechanism which automatically feeds, plays, and rejects a number of records in a preset sequence. It consists of a motor, turntable, pickup arm, and changer. Modern changers are designed to play automatically 16⅔-, 33⅓-, 45-, and 78-rpm records.

automatic relay—A means of selective switching which causes automatic equipment to record and retransmit communications.

automatic reset—1. A stepping relay that returns to its home position either when it reaches a predetermined contact position or when a pulsing circuit fails to energize its driving coil within a given time. 2. An overload relay that restores the circuit as soon as the cause of the overload is corrected.

automatic reset relay—1. A stepping relay that returns to its home position either when it reaches a predetermined contact position or when a pulsing circuit fails to energize the driving coil within a given time. It may either pulse forward or be spring-reset to the home position. 2. An overload relay that restores the circuit as soon as an overcurrent situation is corrected.

automatic scanning—A variable-speed sweep of the entire frequency range of an RFI meter. It may also include the scanning of a portion of this frequency range over a predetermined sector.

automatic scanning receiver—A receiver which can automatically and continuously sweep across a preselected frequency, either to stop when a signal is found or to plot signal occupancy within the frequency spectrum being swept.

automatic selective control (or transfer) relay—A device which operates to select automatically between certain sources or conditions in an equipment, or performs a transfer operation automatically.

automatic sensitivity control—A circuit used for automatically maintaining the receiver sensitivity at a predetermined level. It is similar to an automatic gain control, but it affects the receiver constantly rather than during the brief interval selected by the range gate. 2. The self-acting mechanism which varies the system sensitivity as a function of the specified control parameters. This may include automatic target control, automatic light control, or any combination thereof.

automatic sequencing—The ability of a computer to perform successive operations without additional instructions from a human being.

automatic short-circuit protection—An automatic current-limiting system which enables a power supply to continue operating at a limited current, and without damage, into any output overload, including a short circuit. The output voltage is restored to normal when the overload is removed, as distinguished from a fuse or circuit-breaker system which opens with overload and must be reclosed manually to restore power.

automatic shutoff—In a tape recorder, a switching arrangement which automatically shuts the recorder off when the tape breaks or runs out. Also, a switching arrangement which stops the record changer after the last record.

automatic starter—A device which, after being given the initial impulse by means of a push button or similar device, starts a system or motor automatically in the proper sequence.

automatic target control—The self-acting mechanism which controls the vidicon target potential as a function of the scene brightness.

automatic telegraph transmission—A form of telegraphy in which signals are transmitted mechanically from a perforated tape.

automatic telegraphy—A form of telegraphy in which signals are transmitted and/or received automatically.

automatic threshold variation—A constant false-alarm rate scheme which is an open-loop type of automatic gain control in which the decision threshold is varied continuously in proportion to the incoming intermediate frequency and video noise level.

automatic time switch—A combination of a switch with an electric or spring-wound clock arranged to turn an apparatus on and off at predetermined times.

automatic tracking—In radar, the process whereby a mechanism, actuated by the echo, automatically keeps the radar beam locked on the target, and may also determine the range simultaneously.

automatic transfer equipment—Equipment which automatically transfers a load so that a source of power may be selected from one of several incoming lines.

automatic tuning—An electrical, mechanical, or electrical/mechanical system that automatically tunes a circuit to a predetermined frequency when a button or other control is operated.

automatic video-noise leveling—A constant false-alarm rate scheme in which the video-noise level at the output of the receiver is sampled at the end of each range sweep and the receiver gain is readjusted accordingly to maintain a constant video-noise level at the output.

automatic voltage regulator—A device or circuit which maintains a constant voltage, regardless of any variation in input voltage or load.

automatic volume compression—*See* Volume Compression.

automatic volume control (avc)—1. A self-acting compensation device which maintains the output of a transmission system constant within narrow limits in the face of wide variations in attenuation in that system. 2. A self-acting device which maintains the output of a radio receiver or amplifier substantially constant within relatively narrow limits while the input voltage varies over a wide range. 3. *See also* Automatic Level Compensation.

automatic volume expansion—Also called volume expansion. An audio-frequency circuit that automatically increases the volume range by making loud portions louder and weak ones weaker. This is done to make radio reception sound more like the actual program, because the volume range of programs is generally compressed at the point of broadcast.

automatic zero and full-scale calibration correction—A system of zero and sensitivity stabilization in which electronic servos are used that compare demodulated "zero" and "full-scale" signals with reference voltages.

automation—1. The method or act of making a manufacturing or processing system partially or fully automatic. 2. The entire field of investigation, design, development, application, and methods of rendering or making processes or machines self-acting or self-moving; rendering automatic.

automaton—1. A device that automatically follows predetermined operations or responds to encoded instructions. 2. Any communication-linked set of elements. 3. A machine which exhibits living properties.

automonitor—1. To instruct an automatic digital computer to produce a record of its information-handling operations. 2. A program or routine for this purpose.

autopilot—Also called automatic pilot, gyropilot, or robot pilot. A device containing amplifiers, gyroscopes, and servomotors which automatically control and guide the flight of an aircraft or guided missile. The autopilot detects any deviation from the planned flight and automatically applies the necessary corrections to keep the aircraft or missile on course.

auto radio—A radio receiver designed to be installed in an automobile and powered by the storage battery of the automobile.

autoradiography—Self-portraits of radioactive sources made by placing the radioactive material next to photographic film. The radiations fog the film and thus leave an image of the source.

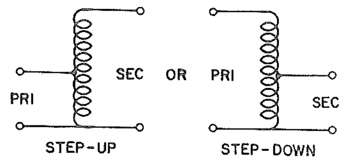
autoregulation induction heater—An induction heater in which a desired control is effected by the change in characteristics of a magnetic charge as it is heated at or near its Curie point.

autostarter—*See* Autotransformer Starter.

Autosyn—A trade name of the Bendix Corp. for a remote-indicating instrument or system based on the synchronous-motor principle in which the angular position of the rotor of a motor at the measuring source is duplicated by the rotor of the indicator motor.

auto tracking—Also called automatic tracking operation. A master/slave connection of two or more power supplies, each of which has one of its output terminals in common with one of the output terminals of all of the other supplies, such connections being characterized by one-knob control and proportional output voltage from all supplies. Useful where simultaneous turn-up, turn-down, or proportional control of all power supplies in a system is required.

autotransformer—1. A transformer with a single winding (electrically) in which the whole winding acts as the primary winding, and only part of the winding acts as the secondary (step-down); or part of the winding acts as the primary and the whole winding acts as the secondary (step-up). 2. A voltage, current, or impedance transforming device in which parts of one winding are common to both the primary and secondary circuits.



Autotransformer.

autotransformer starter—Also called a compensator or autostarter. A motor starter having an autotransformer to furnish a reduced voltage for starting. Includes the necessary switching mechanism.

auxiliary actuator—A mechanism which may be attached to a switch to modify its characteristics.

auxiliary circuit—Any circuit other than the main circuit.

auxiliary contacts—In a switching device, contacts, in addition to the main circuit contacts, which function with the movement of the latter.

auxiliary memory—*See* Auxiliary Storage.

auxiliary relay—1. A relay which responds to the opening or closing of its operating circuit, to assist another relay or device in the performance of a function. 2. A relay actuated by another relay and used to control secondary circuit functions such as signals, lights, or other devices. Also called slave relay.

auxiliary-station line filter—A line filter for use at repeated points to separate frequencies of different carrier systems, using the same line pair. For example, such a filter might be used at a high-frequency carrier-system repeater to bypass the low-frequency carrier system and voice frequencies around the repeater.

auxiliary storage—Also called auxiliary memory. Storage capacity in a digital computer, in addition to the main memory.

auxiliary switch—A switch actuated by some device such as a circuit breaker, for signaling, interlocking, or other purpose.

auxiliary transmitter—A transmitter held in readiness in case the main transmitter of a broadcasting station fails.

availability—1. The ratio, expressed as a percent, of the time during a given period that an equipment is correctly operating to the total time in that period. Also called operating ratio. 2. The probability that a system is operating satisfactorily at any point in time when used under stated conditions, where the total time considered includes operating time, active repair time, administrative time, and logistic time.

available conversion gain—Ratio of available output-frequency power from the output terminals of a transducer to the available input-frequency power from the driving generator, with terminating conditions specified for all frequencies which may affect the result. Applies to outputs of such magnitude that the conversion transducer is operating in a substantially linear condition.

available gain—The ratio of the available power at the output terminals of the network to the available power at the input terminals of the network.

available line—In a facsimile system, that portion of a scanning line which can be used for picture signals. Expressed as a percentage of the length of the scanning line.

available machine time—Time after the application of power during which a computer is operating correctly.

available power—1. The mean square of the open-circuit terminal voltage of a linear source, divided by four times the resistive component of the source impedance. 2. Of a network, the power that would be delivered to a conjugately matched load. It is the maximum power that a network can deliver. Available power, though defined in terms of an output load impedance, is independent of that impedance.

available power gain—Sometimes called completely matched power gain. Ratio of the available power from the output terminals of a linear transducer, under specified input-termination conditions, to the available power from the driving generator. The available power gain of an electrical transducer is maximum when the input-termination admittance is the conjugate of the driving-point admittance at the input terminals of the transducer.

available signal-to-noise ratio—Ratio of the available signal power at a point in a circuit, to the available random-noise power.

avalanche—Rapid generation of a current flow with reverse-bias conditions as electrons sweep across a junction with enough energy to ionize other bonds and create electron-hole pairs, making the action regenerative.

avalanche breakdown—In a semiconductor diode, a nondestructive breakdown caused by the cumulative multiplication of carriers through field-induced impact ionization.

avalanche conduction—A form of conduction in a semiconductor in which charged-particle collisions create additional hole-electron pairs.

avalanche diode—Also called breakdown diode. A silicon diode that has a high ratio of reverse-to-forward resistance until avalanche breakdown occurs. After breakdown the voltage drop across the diode is essentially constant and is independent of the current. Used for voltage regulating and voltage limiting. Originally called zener diode, before it was found that the Zener effect had no significant role in the operation of diodes of this type.

avalanche impedance—*See* Breakdown Impedance.

avalanche noise—A phenomenon in a semiconductor junction in which carriers in a high-voltage gradient develop sufficient energy to dislodge additional carriers through physical impact.

avc—*See* Automatic Volume Control.

average—*See* Arithmetic Mean.

average absolute pulse amplitude—The average of the absolute value of instantaneous amplitude taken over the pulse duration. Absolute value means the arithmetic value regardless of algebraic sign.

average brightness—The average illumination in a television picture.

average calculating operation—A typical computer calculating operation longer than an addition and shorter than a multiplication, often taken as the mean of nine additions and one multiplication.

average electrode current—The value obtained by integrating the instantaneous electrode current over an averaging time and dividing by the average time.

average life—*See* Mean Life.

average noise factor—*See* Average Noise Figure.

average noise figure—Also called average noise factor. In a transducer, the ratio of total output noise power to the portion attributable to thermal noise in the input termination, the total noise being summed over frequencies from zero to infinity and the noise temperature of the input termination being standard (290° K).

average power output of an amplitude-modulated transmitter—The radio-frequency power delivered to the transmitter output terminals, averaged over a modulation cycle.

average pulse amplitude—The average of the instantaneous amplitudes taken over the pulse duration.

average rate of transmission—Effective speed of transmission.

average value—The value obtained by dividing the sum of a number of quantities by the number of quantities. The average value of a sine wave is 0.637 times the peak value.

average voltage—The sum of the instantaneous voltages in a half-cycle waveshape, divided by the number of instantaneous voltages. In a sine wave, the average voltage is equal to 0.637 times the peak voltage.

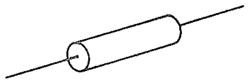
aviation channels—A band of frequencies, below and above the standard broadcast band, assigned exclusively for aircraft and aviation applications.

aviation services—The aeronautical mobile and radionavigation services.

avionics—An acronym designating the field of AVIation electrONICS.

Avogadro's number—The number (N) of molecules in a gram-molecule or the number of atoms in a gram-atom of a substance. The number N = 6.02 × 10^{23} molecules.

AWG—American Wire Gage. A means of specifying wire diameter. The higher the number, the smaller the diameter.



Axial leads.

axial leads—Leads coming out the ends and along the axes of a resistor, capacitor, or other axial part, rather than out the side.

axial ratio—Ratio of the major axis to the minor axis of the polarization ellipse of a wave guide. This term is preferred over ellipticity, because mathematically ellipticity is 1 minus the reciprocal of the axial ratio.

axis—The straight line, either real or imaginary, passing through a body around which the body revolves or around which parts of a body are symmetrically arranged.

Ayrton-Perry winding—Two conductors connected in parallel so that the current flows in opposite directions in each conductor and thus neutralizes the inductance between the two.

Ayrton shunt—Also called universal shunt. A high-resistance parallel connection used to increase the range of a galvanometer without changing the damping.

azel display—A modified type of plan-position indicator presentation showing two separate radar displays on one cathode-ray screen. One display presents bearing information, and the other shows elevation.

azimuth—The angular measurement in a horizontal plane and in a clockwise direction.

azimuth alignment—Alignment of the recording and reproducing gaps so that their center lines lie parallel with one another. Misalignment of the gaps causes a loss in output at short wavelengths.

azimuth gain reduction—A technique which allows control of the radar receiver system throughout any two azimuth sectors.

azimuth rate—The rate of change of true bearing.

azimuth resolution—The angle or distance by which two targets must be separated in azimuth to be distinguished by a radar set, when the targets are at the same range.

azimuth stabilization—The presentation of indications on a radar display so that north, or any specific reference line of direction, is always at the top of the screen.

azimuth-stabilized, plan-position indicator—A ppi scope on which the reference bearing (usually true or magnetic north) remains fixed with respect to the indicator, regardless of the vehicle orientation.

azimuth versus amplitude—An electronic counter-countermeasures receiver with plan-position indicator-type display attached to the main antenna, used to display strobes due to jamming aircraft. It is useful in making passive fixes when two or more radar sites can operate together.

azusa—A short base-line continuous-wave phase-comparison electronic tracking system operating on the C-band, wherein a single station provides two direction cosines and slant range.

B

B—1. Symbol for the base of a transistor. 2. Symbol for magnetic flux. 3. Abbreviation for photometric brightness. 4. B or b. Abbreviation for susceptance.

B− (B-minus or B-negative)—Negative terminal of a B battery or the negative polarity of other sources of anode voltage. Denotes the terminal to which the negative side of the anode-voltage source should be connected.

B+ (B-plus or B-positive)—Positive terminal of a B battery or the positive polarity of other sources of anode voltage. The terminal to which the positive side of the anode voltage source should be connected.

babble—1. The aggregate cross talk from a large number of disturbing channels. 2. In a carrier, or other multiple-channel system, the unwanted disturbing sounds which result from the aggregate cross talk or mutual interference from other channels.

babble signal—A type of electronic deception signal used to confuse enemy receivers. Generally it has characteristics of enemy transmission signals. It can be composed by superimposing incoming signals on previously recorded intercepted signals. This composite signal can then be radiated as a jamming signal.

BABS (Blind Approach Beacon System)—A pulse-type ground-based navigation beacon used for runway approach. The BABS ground beacon is installed beyond the far end of the runway on the extended center line. When interrogated by an aircraft, it retransmits two diverging beams, one of short and the other of long duration pulses. The beams are transmitted alternately, but because of the fast switching, the aircraft receives what appears to be a continuous transmission of both beams. The cathode-ray tube in the aircraft displays both long and short pulses superimposed on each other. When the aircraft is properly aligned with the runway, the pulses will be of equal amplitude.

back bias—1. A degenerative or regenerative voltage which is fed back to circuits before its originating point. Usually applied to a control anode of a tube. 2. A voltage applied to a grid of a tube (or tubes) to restore a condition which has been upset by some external cause. 3. *Also see* Reverse Bias.

backbone—A high-voltage, high-capacity transmission line or group of lines having a limited number of large-capacity connections between loads and points of generation.

back contact—Relay, key, jack, or other contact designed to close a circuit and permit current to flow when, in the case of a relay, the armature has released or fallen back, or in other cases, when the equipment is inoperative.

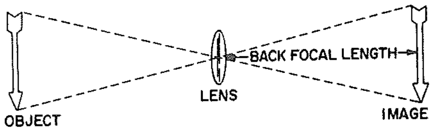
back current—Also called reverse current. The current which flows when reverse bias is applied to a semiconductor junction.

back diode—A tunnel diode that is usually chosen for its reverse-conduction characteristics.

back echo—An echo due to the back lobe of an antenna.

back emission—Also called reverse emission. Emission from an electrode occurring only when the electrode has the opposite polarity from that required for normal conduction. A form of primary emission common to rectifiers during the inverse portion of their cycles.

backfire—*See* Arcback.



Back focal length.

back focal length—Distance from the center of a lens to its principal focus on the side of the lens away from the object.

background—1. The picture white of the copy being scanned when the picture is black and white only. Also undesired printing in the recorded copy of the picture being transmitted, resulting in shading of the background area. 2. Noise heard during a radio program; this noise is caused by atmospheric interference or operation of the receiver at such high gain that inherent tube and circuit noises become noticeable.

background control—In color television, a potentiometer used as a means of controlling the d-c level of a color signal at one input of a tricolor picture tube. The setting of this control determines the average (or background) illumination produced by the associated color phosphor.

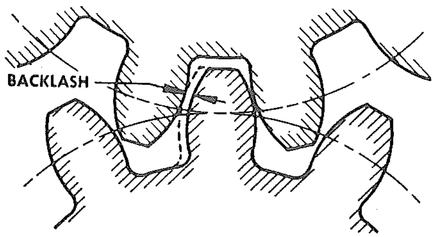
background count—Count caused by radiation from sources other than the one being measured.

background noise—1. The total system noise, independent from the presence or absence of a signal. The signal is not included as part of the noise. 2. In a receiver, the noise in the absence of signal modulation in the carrier. 3. Any unwanted sound that intrudes upon program material, such as sounds produced as a result of surface imperfections of a disc record.

background radiation—Radiation due to the presence of radioactive material in the vicinity of the measuring instrument.

background response—In radiation detectors, response caused by ionizing radiation from sources other than that to be measured.

backlash—1. In a potentiometer, the maximum difference that occurs in shaft position when the shaft is moved to the same actual output-ratio point from opposite directions. Resolution and contact-width effects must be excluded from this measure. 2. The shortest distance between nondriving tooth surfaces of adjacent teeth in mating gears or the amount of clearance between the teeth or mating gears. Usually measured at the common pitch circle.



Backlash.

backloaded horn—A speaker enclosure arranged so the sound from the front of the cone feeds directly into the room, while the sound from the rear feeds into the room via a folded horn.

back loading—A form of horn loading particularly applicable to low-frequency speakers; the rear radiating surface of the speaker feeds the horn and the front part of the speaker is directly exposed to the room.

back lobe—In the radiation pattern of a directional antenna, that part which extends backward from the main lobe.

back pitch—The winding pitch of the back end of the armature—that is, the end opposite the commutator.

backplate—In a camera tube, the electrode to which the stored-charge image is capacitively coupled.

back porch—In a composite picture signal, that portion which lies between the trailing edge of a horizontal-sync pulse and the trailing edge of the corresponding blanking pulse. A color burst, if present, is not considered part of the back porch.

back-porch effect—The continuation of collector current in a transistor for a short time after the input signal has dropped to zero. The effect is due to storage of minority carriers in the base region. It also occurs in junction diodes.

back-porch tilt—The slope of the back porch from its normal horizontal position. Positive and negative refer respectively to upward and downward tilt to the right.

back scatter — Return, due to scatter, of a portion of electromagnetic radiation toward its source.

backscatter—Propagation of extraneous signals by F- or E- region reflection in addition to the desired ionospheric scatter mode. The undesired signal enters the antenna through the back lobes.

back scattering—1. Radiation of unwanted energy to the rear of an antenna. 2. The reflected radiation of energy from a target toward the illuminating radar.

back-shunt keying—A method of keying a transmitter, in which the radio-frequency energy is fed to the antenna when the telegraph key is closed and to an artificial load when the key is open.

backstop—That part of the relay which limits the movement of the armature away from the pole face or core. In some relays, a normally closed contact may serve as a backstop.

backswing—The amplitude of the first maximum excursion in the negative direction after the trailing edge of a pulse expressed as a percentage of the 100% amplitude.

back-to-back circuit — Two tubes or semiconductor devices connected in parallel but in opposite directions so that they can be used to control current without introducing rectification. Also called inverse-parallel connection.

backup—1. An item kept available to replace an item which fails to perform satisfactorily. 2. An item under development intended to perform the same general function performed by another item also under development.

backup facility—A communications-electronics facility which is established for the purpose of replacing or supplementing another facility or facilities, under real or simulated emergency conditions.

backup item—An additional item to perform the general functions of another item. It may be secondary to an identified primary item or a parallel development to improve the probability of success in performing the general function.

backwall—The plate in a pot core which connects the center post to the sleeve.

backwall photovoltaic cell—A cell in which light must pass through the front electrode and a semiconductor layer before reaching the barrier layer.

backward-acting regulator—A transmission regulator in which the adjustment made by the regulator affects the quantity which caused the adjustment.

backward diode — A highly doped, alloyed germanium junction that operates on the principle of quantum-mechanical tunneling. The diode is "backward" because its easy-current direction is in the negative-voltage rather than the positive-voltage region of the i-v curve. The backward diode has a negative-resistance region, but the resultant "valley" of its i-v curve is much less pronounced than in tunnel diodes.

backward wave—In a traveling-wave tube, a wave having a group velocity opposite the direction of electron-stream motion.

backward-wave oscillator—An oscillator employing a special vacuum tube in which oscillatory currents are produced by using an oscillatory electromagnetic field to bunch the electrons as they flow from cathode to anode.

backward-wave tube—A traveling-wave tube in which the electrons travel in a direction opposite to that in which the wave is propagated.

back wave—*See* Spacing Wave.

baffle—1. In acoustics, a shielding structure or partition used to increase the effective length of the external transmission path between two points (for example, between the front and back of an electroacoustic transducer). A baffle is often used in a speaker to increase the acoustic loading of the diaphragm. 2. In a gas tube, an auxiliary member placed in the arc path and having no separate external connection. 3. A device for deflecting oil or gas in a circuit breaker.

baffle plate—A metal plate inserted into a waveguide to reduce the cross-sectional area for wave-conversion purposes.

bail—A loop of wire used to prevent permanent separation of two or more parts assembled together—e.g., the bail holding dustcaps on round connectors.

Bakelite—A trademark of the Bakelite Corp. for its line of plastic and resins. Formerly, the term applied only to its phenolic compound used as an insulating material in the construction of radio parts.

balance—1. The effect of blending the volume of various sounds coming over different microphones in order to present them in correct proportion. 2. The maintenance of equal average volume from both speaker systems of a stereo installation.

balance control—On a stereo amplifier, a differential gain control used to vary the volume of one speaker system relative to the other without affecting the over-all volume level. As the volume of one speaker increases and the other decreases, the sound appears to shift from left to center to right, or vice versa.

balanced—1. Electrically alike and symmetrical with respect to ground. 2. Arranged to provide balance between certain sets of terminals.

balanced amplifier—An amplifier circuit with two identical signal branches, connected to operate in phase opposition and with their input and output connections each balanced to ground; for example, a push-pull amplifier.

balanced armature—An armature which is approximately in equilibrium with respect to both static and dynamic forces.

balanced-armature unit—The driving unit used in magnetic speakers, consisting of an iron armature pivoted between the poles of a permanent magnet and surrounded by coils carrying the audio-frequency current. Variations in the audio-frequency current cause corresponding changes in the armature magnetism and corresponding movements of the armature with respect to the poles of the permanent magnet.

balanced circuit—1. A circuit with two sides electrically alike and symmetrical to a common reference point, usually ground. 2. A circuit terminated by a network that has infinite impedance losses.

balanced converter—*See* Balun.

balanced currents — Also called push-pull currents. In the two conductors of a balanced line, currents which are equal in value and opposite in direction at every point along the line.

balanced detector—A demodulator for frequency-modulation systems. In one form, the output consists of the rectified difference of the two voltages produced across two resonant circuits, one circuit being tuned slightly above the carrier frequency and the other slightly below.

balanced line—A line or circuit utilizing two identical conductors. Each conductor is operated so that the voltages on them at any transverse plane are equal in magnitude and opposite in polarity with respect to ground. Thus, the currents on the line are equal in magnitude and opposite in direction. A balanced line is preferred where minimum noise and cross talk are desired.

balanced-line system—A system consisting of a generator, balanced line, and load adjusted so that the voltages of the two conductors at all transverse planes are equal in magnitude and opposite in polarity with respect to ground.

balanced low-pass filter — A low-pass filter designed to be used with a balanced line.

balanced method — A method of measurement in which the reading is taken at zero. It may be a visual or audible reading, and in the latter case the null is the no-sound setting.

balanced modulator—An amplitude modulator in which the control grids of two tubes are connected for parallel operation, and the screen grids and plates for push-pull operation. After modulation, the output contains the two sidebands without the carrier.

balanced network — A hybrid network in which the impedances of the opposite branches are equal.

balanced oscillator—Any oscillator in which (1) the impedance centers of the tank circuits are at ground potential and (2) the voltages between either end and the centers are equal in magnitude and opposite in phase.

balanced termination—For a system or network having two output terminals, a load presenting the same impedance to ground for each output terminal.

balanced transmission line—A transmission line having equal conductor resistances per unit length and equal impedances from each conductor to earth and to other electrical circuits.

balanced voltages — Also called push-pull voltages. On the two conductors of a balanced line, voltages (relative to ground) which are equal in magnitude and opposite in polarity at every point along the line.

balanced-wire circuit—A circuit with two sides electrically alike and symmetrical to ground and other conductors. Commonly refers to a circuit the two sides of which differ only by chance.

balancer—In a direction finder, that portion used for improving the sharpness of the direction indication. It balances out the capacitance effect between the loop and ground.

balance-to-unbalance transformer — A device for matching a pair of lines, balanced with respect to earth, to a pair of lines not balanced with respect to earth.

balancing network — An electrical network designed for use in a circuit in such a way that two branches of the circuit are made substantially conjugate (i.e., such that an electromotive force inserted into one branch produces no current in the other).

balancing unit—1. An antenna-matching device used to permit efficient coupling of a transmitter or receiver having an unbalanced output circuit to an antenna having a balanced transmission line. 2. A device for converting balanced to unbalanced transmission lines, and vice versa, by placing suitable discontinuities at the junction between the lines instead of using lumped components.

ball—In face bonding, a method of providing chips with contact.

ballast lamp—A lamp which maintains a nearly constant current by increasing its resistance as the current increases.

ballast resistor—A special type of resistor used to compensate for fluctuations in alternating-current power-line voltage. It is usually connected in series with the power supply to a receiver or amplifier. The resistance of a ballast resistor increases rapidly with increases in current through it, thereby tending to maintain an essentially constant current despite variations in the line voltage.

ballast tube—A current-controlling resistance device designed to maintain a substantially constant current over a specified range of variations in the applied voltage to a series circuit.

ball bonding—A type of thermocompression bonding which uses a flame to cut a wire as it leaves a capillary feed tube. The molten end of the wire solidifies into a ball, which is pressed against the bonding pad on an integrated circuit.

ballistic galvanometer—An instrument that indicates the effect of a sudden rush of electrical energy, such as the discharge current of a capacitor.

ballistic-missile early-warning system—An electronic system for providing detection and early warning of attack by enemy intercontinental ballistic missiles.

ballistic trajectory—In the trajectory of a missile, the curve traced after the propulsive force is cut off and the body of the missile is acted upon only by gravity, aerodynamic drag, and wind.

ballistocardiogram—A waveform of the impulse imparted to or incurred by the body as a result of the displacement of blood upon each heartbeat. The period of the cycle of this waveform is the time interval between heart beats. Typically taken in one of two ways—by measuring the seismic disturbance imparted to the table upon which the patient is lying supine, or by measuring the deflection of a heavy metal bar placed across the patient's ankles while he is lying supine.

balop—Contraction of balopticon, an apparatus for the projection of opaque images in conjunction with a television camera.

balopticon—*See* Balop.

balun — Also called balanced converter or "bazooka." An acronym from BALanced to UNbalanced. A device used for matching an unbalanced coaxial transmission line to a balanced two-wire system.

banana jack—A jack that accepts a banana plug. Generally designed for panel mounting.

banana plug—A plug with a banana-shaped spring-metal tip and with elongated springs to provide a low-resistance compression fit.

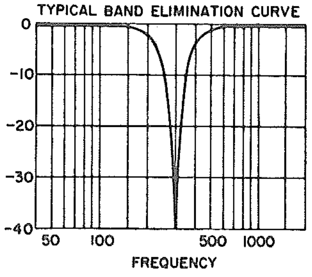
band—1. Any range of frequencies which lies between two defined limits. 2. A group of radio channels assigned by the FCC to a particular type of radio service:

Very low freq.	(vlf)	10-30 kHz.
Low freq.	(lf)	30-300 kHz.
Medium freq.	(mf)	300-3,000 kHz.
High freq.	(hf)	3-30 MHz.
Very high freq.	(vhf)	30-300 MHz.
Ultrahigh freq.	(uhf)	300-3,000 MHz.
Superhigh freq.	(shf)	3,000-30,000 MHz.
Extremely high freq.	(ehf)	30-300 GHz.

3. A group of tracks or channels on a magnetic drum in an electronic computer. (*Also see* Track.)

band center—The geometric mean between the limits of a band of frequencies.

banded cable — Two or more cables banded together by stainless-steel strapping.



Band-elimination filter characteristic.

band-elimination filter—Also called band-stop filter. A wave filter with a single attenuation band, neither of the cutoff frequencies being zero or infinite. The filter passes frequencies on either side of this band.

bandpass—The number of hertz expressing the difference between the limiting frequencies at which the desired fraction (usually half-power) of the maximum output is obtained.

bandpass-amplifier circuit—A stage designed to uniformly amplify signals of certain frequencies only.

bandpass filter—A wave filter with a single transmission band, neither of the cutoff frequencies being zero or infinite. The filter attenuates frequencies on either side of this band.

bandpass flatness—The variations in gain in the bandpass of a filter or tuned circuit.

bandpass response—Also called flat-top response. The response characteristic in which a definite band of frequencies is transmitted uniformly.

band-rejection filter—A filter having a single attenuation band, with neither of the cutoff frequencies being zero or infinite.

band selector—Also called bandswitch. A switch used to select any one of the bands in which a receiver, signal generator, or transmitter is designed to operate.

B and S gage—Brown and Sharpe wire gage, where the conductor sizes rise in geometrical progression. Adopted as the American Wire Gage standard.

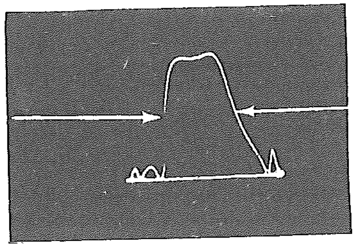
bandspreading—1. The spreading of tuning indications over a wide range to facilitate tuning in a crowded band of frequencies. 2. The method of double-sideband transmission in which the frequency band of the modulating wave is shifted upward so that the sidebands produced by modulation are separated from the carrier by a frequency at least equal to the bandwidth of the original modulating wave. In this way, second-order distortion products may be filtered out of the demodulator output.

bandspread tuning control—A separate tuning control provided on some short-wave receivers to spread the stations in a single band of frequencies over an entire tuning dial.

band-stop filter — *See* Band-Elimination Filter.

bandswitch—A switch used to select any one of the frequency bands in which an electronic apparatus may operate.

bandwidth—1. The range within the limits of a band. The width of a bandpass filter is generally taken as the limits between which its attenuation is not more than 3.0 decibels greater than its average attenuation throughout its passband. Also used in connection with receiver selectivity, transmitted frequency spectrum occupancy, etc. 2. In a given facsimile system, the difference in hertz between the highest and lowest frequency components required for the adequate transmission of the facsimile signals. 3. The least frequency interval of a wave, outside of which the power spectrum of a time-varying quantity is everywhere less than some specified fraction of its value at a reference frequency. 4. The range of frequencies of a device, within which its performance, with respect to some characteristic, conforms to a specified standard.



Bandwidth.

bang-bang controller — A discontinuity-type nonlinear system that contains time delay, dead space, and hysteresis.

bank—An aggregation of similar devices (e.g. transformers, lamps, etc.) connected and used together. In automatic switching, a bank is an assemblage of fixed contacts over which one or more wipers or brushes move to establish electric connections.

bank-and-wiper switch—A switch in which the electromagnetic ratchets or other mechanisms are used, first, to move the wipers to a desired group of terminals, and second, to move the wipers over the terminals of this group to the desired bank contacts.

bank winding—Also called banked winding. A compact multilayer form of coil winding used for reducing distributed capacitance. Single turns are wound successively in two or more layers, the entire winding proceeding from one end of the coil to the other without being returned.

bantam tube — A compact tube having a standard octal base but a considerably smaller glass envelope than the standard glass octal tube has.

bar—1. *See* Microbar. 2. A subdivision of a crystal slab. 3. A vertical or horizontal line on a television screen, used for testing.

bare conductor — A conductor not covered with any insulating material.

bar generator—A generator of pulses or repeating waves which are equally separated in time. These pulses are synchronized by the synchronizing pulses of a television system so that they produce a stationary bar pattern on a television screen.

bar-graph monitoring oscilloscope—An oscilloscope for observation of commutated signals appearing as a series of bars with lengths proportional to channel modulation. The same oscilloscope is commonly used for setup and troubleshooting observations.

barium—An element the oxide of which is used in the cathode coating of vacuum tubes.

barium titanate—A ceramic that has electric properties and is capable of withstanding much higher temperatures than Rochelle salt crystals. Used in crystal pickups and sonar transducers.

Barkhausen effect—A succession of abrupt changes which occur when the magnetizing force acting on a piece of iron or other magnetic material is varied.

Barkhausen interference — Interference caused by Barkhausen oscillations.

Barkhausen-Kurz oscillator — Circuit for generating ultrahigh frequencies. Its operation depends on the variation in the electrical field around the positive grid and less positive plate of a triode; the variation is caused by oscillatory electrons in the interelectrode spaces.

Barkhausen oscillation—A form of parasitic oscillation in the horizontal-output tube of a television receiver; it results in one or more narrow, dark, ragged vertical lines near the left side of the picture or raster.

Barkhausen oscillator—*See* Barkhausen-Kurz Oscillator.

Barkhausen tube—*See* Positive-Grid Oscillator Tube.

bar magnet—A bar of metal that has been so strongly magnetized that it holds its magnetism and thereby serves as a permanent magnet.

barn—A unit of measure of nuclear cross sections. Equal to 10^{-24} square centimeters.

Barnett effect—The magnetization resulting from the rotation of a magnetic specimen. The rotation of a ferromagnet produces the same effect as placing the ferromagnet in a magnetic field directed along the axis of rotation. On the macroscopic model, the domains of a ferromagnet can be considered a group of electron systems, each acting as an independent gyroscope or gyrostat.

barometer—An instrument for measuring atmospheric pressure. There are two types of barometers commonly used in meteorology—the mercury barometer and the aneroid barometer.

barometric pressure—The weight of the atmosphere per unit of surface. The standard barometer reading at sea level and 59° F is 29.92 inches of mercury absolute.

bar pattern—A pattern of repeating lines or bars on a television screen. When such a pattern is produced by pulses which are equally separated in time, the spacing between the bars on the television screen can be used to measure the linearity of the horizontal or vertical scanning systems.

bar quad—*See* B-quad.

barrage jamming—Simultaneous jamming of a number of adjacent channels or frequencies.

bar relay—A relay in which a bar actuates several contacts simultaneously.

barrel distortion—In camera or image tubes, the distortion which results in a monotonic decrease in radial magnification in the reproduced image away from the axis of symmetry of the electron optical system. In tv receivers, barrel distortion makes all four sides of the raster curve out like a barrel.

barretter—A voltage-regulator tube consisting of an iron-wire filament in a hydrogen-filled envelope. The filament is connected in series with the circuit to be regulated and maintains a constant current over a given voltage variation.

barretter mount — A wave-guide mount in which a barretter can be inserted to measure electromagnetic power.

barricade shield—A type of movable shield for protection from radiation.

barrier—A partition for the insulation or isolation of electric circuits or electric arcs.

barrier capacitance — *See* Depletion-Layer Capacitance.

barrier-film rectifier — A rectifier in which a film having unilateral (single-direction) conductivity is in contact with metal or other normally conducting plates.

barrier grid—A grid close to, or in contact with, a storage surface of a charge storage tube. It establishes an equilibrium voltage for secondary-emission charging and serves to minimize redistribution.

barrier layer—*See* Depletion Layer.

barrier-layer cell — A type of photovoltaic cell in which light acting on the surface of the contact between layers of copper and cuprous oxide causes an electromotive force to be produced.

barrier-layer rectification—*See* Depletion-Layer Rectification.

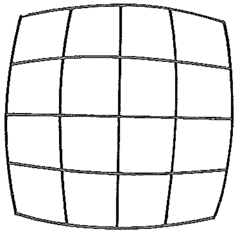
barrier region—*See* Depletion Region.

barrier shield—A wall or enclosure shielding the operator from an area where radioactive material is being used or processed by remote-control equipment.

barrier voltage — The voltage necessary to cause electrical conduction in a junction of two dissimilar materials, such as a P-N junction diode.

base—1. The region between the emitter and collector of a transistor which receives minority carriers injected from the emitter. It is the element which corresponds to the control grid of an electron tube. 2. In a vacuum tube, the insulated portion through which the electrodes are connected to the pins. 3. On a printed-circuit board, the portion that supports the printed pattern. 4. *Also see* Positional Notation and Radix. 5. *See* Alkali.

baseband—The frequency band occupied by the aggregate of the transmitted signals used to modulate a carrier. The term is commonly applied where the ratio of the upper to the lower limit of the frequency band is larger than unity.



Barrel distortion.

base electrode—An ohmic or majority-carrier contact to the base region of a transistor.

base film — The plastic substrate that supports the coating of magnetic recording tape. The base film of most instrumentation and computer tapes is made of polyester. For less critical uses, cellulose acetate and polyvinyl chloride are employed.

basegroup—Designating a number of carrier channels in a particular frequency range that forms a basic unit (channel bank) for further modulation to a final frequency band.

base insulator — Heavy-duty insulator used to support the weight of an antenna mast and to insulate the mast from the ground of some other surface.

base line — 1. In radar displays, the visual line representing the track of the radar scanning beam. 2. In graphical presentations, the horizontal scale, often representing time, bias, or some other variable.

base-line break — In radar, a technique which uses the characteristic break in the base line on an A-scope display due to a pulse signal of significant strength in noise jamming.

base load—In a d-c converter, the current which must be taken from the base to maintain a saturated state.

base-loaded antenna—A vertical antenna the electrical height of which is increased by adding inductance in series at the base.

base material—An insulating material (usually a copper-clad laminate) used to support a conductive pattern.

base number—The radix of a number system (10 is the base number, or radix, for the decimal system; 2 for the binary system).

base pin—*See* Pin.

base point—*See* Radix Point.

base region—In a transistor, the interelectrode region into which minority carriers are injected.

base resistance—Resistance in series with the base lead in the common-T equivalent circuit of a transistor.

base ring—Ohmic contact to the base region of power transistors; so called because it is ring-shaped.

base spreading resistance—In a transistor, the resistance of the base region caused by the resistance of the bulk material of the base region.

base station—A land station, in the land mobile service, carrying on a service with land mobile stations. (A base station may secondarily communicate with other base stations incident to communications with land mobile stations.) Sometimes defined as a station in a land mobile system which remains in a fixed location and communicates with mobile stations.

base voltage—The voltage between the base terminals of a transistor and the reference point.

basic frequency—In any wave, the frequency which is considered the most important. In a driven system, it would in general be the driving frequency, while in most periodic waves it would correspond to the fundamental frequency.

basic linkage—In a computer, a linkage that is used repeatedly in one routine, program, or system and that follows the same set of rules each time it is used.

basic-*Q*—*See* Nonloaded *Q*.

basic rectifier—A metallic rectifier in which each rectifying element consists of a single metallic rectifier cell.

basic switch—A precision snap-acting switch of either the open type, skeleton type, or the type encased within an envelope. A basic switch is normally used within a protective enclosure or as a component.

basket winding—A coil winding in which adjacent turns are separated except at the points of crossing.

bass—Sounds in the low audio-frequency range. On the standard piano keyboard, all notes below middle *C* (256 hertz).

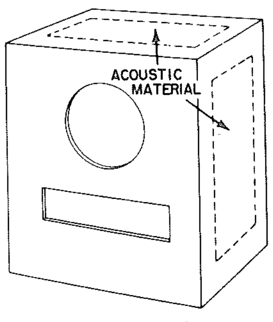
bass boost—A deliberate adjustment of the amplitude-frequency response of a system or component to accentuate the lower audio frequencies.

bass-boosting circuit—A circuit that attenuates the higher audio frequencies in order that low or bass frequencies will be emphasized by comparison.

bass compensation—Emphasizing the low-frequency response of an audio amplifier at low volume levels to compensate for the lowered sensitivity of the human ear to weak low frequencies.

bass control—A manual tone control that has the effect of changing the level of bass frequencies reproduced by an audio amplifier.

bass reflex—A method of extending the low-frequency range of a speaker and its response. Accomplished by an opening in the cabinet enclosing the speaker.



Bass-reflex enclosure.

bass-reflex enclosure—*See* Vented Baffle.

bass response—1. The extent to which a speaker or audio-frequency amplifier handles low audio frequencies. 2. The ability of any device to pick up or reproduce low audio frequencies.

batch process—A method of fabricating monolithic resistors, capacitors, and diodes with the same process at the same time.

batch processing—In a computer, a method of processing in which a number of similar input items are grouped for processing during the same machine run.

bat handle—Standard form of a toggle-switch lever having a shape similar to that of a baseball bat.

bathtub capacitor—A type of capacitor enclosed in a metal housing having broadly rounded corners like those on a bathtub.

bathyconductorgraph—A device used from a moving ship to measure the electrical conductivity of sea water at various depths.

bathythermograph—A device that automatically plots a graph showing temperature as a function of depth when lowered into the sea.

Batten system—A method developed by W. E. Batten for coordinating single words in a computer to identify a document. Sometimes called peek-a-boo system.

battery—A d-c voltage source consisting of two or more cells which converts chemical, nuclear, solar, or thermal energy into electrical energy.

battery acid—A solution that serves as the electrolyte in a storage battery. In the common lead-acid storage battery, the electrolyte is diluted sulphuric acid.

battery capacity—The amount of energy obtainable from a storage battery, usually expressed in ampere-hours.

battery charger—Device used to convert alternating current into a pulsating direct current which can be used for charging a storage battery.

battery clip—A metal clip with a terminal to which a connecting wire can be attached, and with spring jaws that can be quickly snapped onto a battery terminal or other point to which a temporary connection is desired.

battery receiver—A radio receiver that obtains its operating power from one or more batteries.

battle short—A switch for short-circuiting safety interlocks and lighting a red warning light.

bat wing—An element on an f-m or tv transmitting or receiving antenna; so called because of its shape.

baud—A unit of signaling speed derived from the duration of the shortest code element. Speed in bauds is the number of code elements per second.

bay—1. A portion of an antenna array. 2. A vertical compartment in which a radio transmitter or other equipment is housed.

bayonet base—A base having two projecting pins on opposite sides of a smooth cylindrical base; the pins engage corresponding slots in a bayonet socket and hold the base firmly in the socket.

bayonet coupling—A quick-coupling device. Connection is accomplished by rotating two parts under pressure. Pins on the side of the male connector engage slots on the side of the female connector.

bayonet socket—A socket for bayonet-base tubes or lamps; it has slots on opposite sides and one or more contact buttons at the bottom.

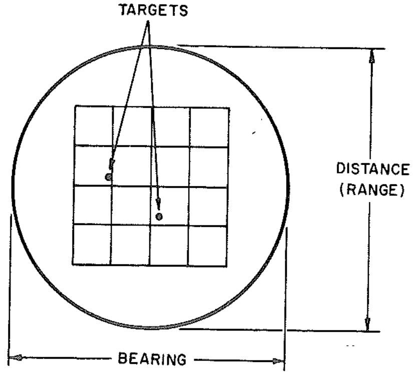
bazooka—*See* Balun.

B battery—The battery that furnishes the required d-c voltages to the plate and screen-grid electrodes of the vacuum tubes in a battery-operated circuit.

BCD—Abbreviation for Binary-Coded Decimal.

B channel—One of two stereo channels, usually the right, together with the microphone, speakers, or other equipment associated with this channel.

BCI—Abbreviation for BroadCast Interference, a term denoting interference by transmitters with reception of broadcast signals on standard broadcast receivers.



B-display.

B-display—On a radarscope, a type of presentation in which the target appears as a bright spot. Its bearing is indicated by the horizontal coordinate and its range by the vertical coordinate.

beacon—A device which emits a signal for use as a guidance or warning aid. Radar beacons aid the radar set in locating and identifying special targets which may otherwise be difficult or impossible to sense.

beacon delay—The amount of inherent delay within the beacon—i.e., the time between the arrival of a signal and the response of the beacon. In a pulse beacon, delay ordinarily is measured between the leading db points of the triggering pulse and the reply pulse.

beacon receiver—A radio receiver for converting into perceptible signals the waves emanating from a radio beacon.

beacon skipping—A term used to describe a condition where beacon return pulses are missing at the interrogating radar. Beacon skipping can be caused by interference, over-interrogation of the beacon, antenna nulls, or pattern minima.

beacon stealing—The loss of beacon tracking by a (desired) radar due to (interfering) interrogation signals from another radar.

beacon time sharing—A technique by which two or more radars may interrogate and track a long-recovery type of beacon without exceeding the duty cycle of the beacon. This technique is accomplished by the proper sequencing of the various radar interrogations. It is necessary to insure that the total of all interrogations does not exceed the beacon duty cycle and that enough time is allowed for the modulator section of the beacon to recover before it receives the next interrogation.

beaded coax—A coaxial cable in which the dielectric consists of beads made of various materials.

beaded support—Ceramic and plastic beads used to support the inner conductor in coaxial transmission lines.

beaded transmission line—A line using beads to support the inner conductor in coaxial transmission lines.

bead thermistor—A thermistor consisting of a small bead of semiconducting material such as germanium placed between two wire leads. Used for microwave power measurement, temperature measurement, and as a protective device. The resistance decreases as the temperature increases.

beam—1. A flow of electromagnetic radiation concentrated in a parallel, converging, or diverging pattern. 2. The unidirectional or approximately unidirectional flow of radiated energy or particles.

beam alignment—The adjustment of the electron beam in a camera tube (on tubes employing low-velocity scanning) to cause the beam to be perpendicular to the target at the target surface.

beam angle—The angle between the directions, on either side of the axis, at which the intensity of the radio-frequency field drops to one-half the value it has on the axis.

beam antenna—An antenna that concentrates its radiation into a narrow beam in a definite direction.

beam bender—*See* Ion-Trap.

beam bending—Deflection of the scanning beam of a camera tube by the electrostatic field of the charges stored on the target.

beam blanking—Interruption of the electron beam in a cathode-ray tube by the application of a pulse to the control grid or cathode.

beam candlepower—The candlepower of a bare source which, if located at the same distance as the beam, would produce the same illumination as the beam.

beam convergence—The converging of the three electron beams of a three-gun color picture tube at a shadow mask opening.

beam crossover—The point of overlap of a beam from an antenna that is mutated or rotated about the center line of the antenna radiation direction. The crossover point is normally at the 0.7 power point. The received energy, when commutated into four quadrants, provides the necessary information for the servoamplifier error signal used to align the antenna to a target.

beam-coupling coefficient—In a microwave tube, the ratio of the amplitude, expressed in volts, of the velocity modulation produced by a gap to the radio-frequency gap voltage.

beam current—The current carried by the electron stream that forms the beam in a cathode-ray tube.

beam cutoff—In a television picture tube or cathode-ray tube, the condition in which the control-grid potential is so negative with respect to the cathode that electrons cannot flow and thereby form the beam.

beam-deflection tube—An electron-beam tube in which current to an output electrode is controlled by the transverse movement of an electron beam.

beam-forming electrode—Electron-beam focusing elements in power tetrodes and cathode-ray tubes.

beam hole—An opening through a reactor shield and, generally, through the reactor reflector which permits a beam of radioactive particles or radiation to be used for experiments outside the reactor.

beam-index color tube—A color picture tube in which the signal generated by an electron beam after deflection is fed back to a control device or element in such a way that an image in color is provided.

beam-lead bonding—A free-bonding technique in which thick, gold extensions of the thin-film terminals of the semiconductor devices and circuits are electroformed so they extend beyond the edges of the chips.

beam modulation—*See* Z-Axis Modulation.

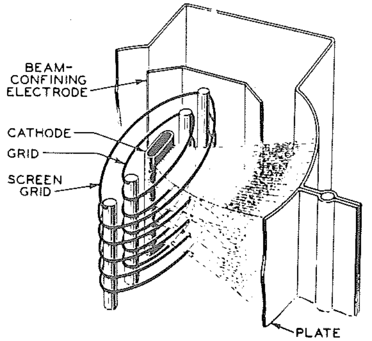
beam parametric amplifier—A parametric amplifier in which a modulated electron beam provides a variable reactance.

beam-positioning magnet—A magnet used with a tricolor picture tube to influence the direction of one of the electron beams so that it will have the proper spatial relationship with the other two beams.

beam-power tube—An electron-beam tube in which directed electron beams are used to contribute substantially to its power-handling capability, and in which the control and screen grids essentially are aligned.—*See* illustration on page 52.

beam relaxor—A type of sawtooth scanning-oscillator circuit which generates but does not amplify the current wave required for magnetic deflection in a single beam-power pentode.

beam-rider control system—A system whereby the control station sends a beam to



Beam-power tube.

the target, and the missile follows this beam until it collides with the target.

beam-rider guidance—A form of missile guidance wherein a missile, through a self-contained mechanism, automatically guides itself along a radar beam.

beam splitting—A process for increasing the accuracy in locating targets by radar. By noting the azimuths at which one radar scan first discloses a target and at which radar data from it ceases, beam splitting calculates the mean azimuth for the target.

beam spreader—An optical element the purpose of which is to impart a small angular divergence to a colliminated incident beam.

beam switching—A method of obtaining more accurately the bearing and/or elevation of an object by comparing the signals received when the beam is in a direction differing slightly in bearing and/or elevation. When these signals are equal, the object lies midway between the beam axes.

beam-switching tube—A multiposition, high-vacuum, constant-current distributor. The beam-switching tube consists of many identical "arrays" around a central cathode. Each array comprises (1) a spade which automatically forms and locks the electron beam, (2) a target-output electrode which gives the beam current its constant characteristics, and (3) a high-impedance switching grid which switches the beam from target to target. A small cylindrical magnet, permanently attached to the glass envelope, provides a magnetic field. This field, in conjunction with an applied electric field, comprises the crossed fields necessary for operation of this tube. It is used in electronic switching and in distributing such as counting, timing, sampling, frequency dividing, coding, matrixing, telemetering, and controlling.

CATHODE

Beam-switching tube.

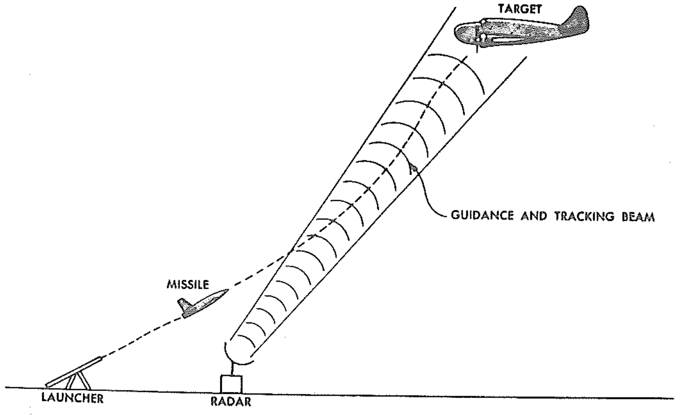
beam width—1. The angular width of a radio, radar, or other beam measured between two reference lines. 2. The width of a radar beam measured between lines of half-power intensity.

bearing—1. The horizontal direction of an object or point, usually measured clockwise from a reference line or direction through 360°. 2. Support for a rotating shaft. 3. The horizontal angle at a given point, measured from a specific reference datum, to a second point relative to another as measured from a specific reference datum.

bearing cursor—A mechanical bearing line of a plan-position indicator type of display for reading the target bearing.

bearing loss—The loss of power through friction in the bearings of an electric motor (brushes removed and no current in the windings).

bearing resolution—The minimum angular separation in a horizontal plane between two targets at the same range that will allow an operator to obtain data on either individual target.



Beam-rider guidance.

beat—Periodic variations that result from the superimposition of waves having different frequencies. The term is applied both to the linear addition of two waves, resulting in a periodic variation of amplitude, and to the nonlinear addition of two waves, resulting in new frequencies, of which the most important usually are the sum and difference of the original frequencies.

beat frequency—One of the two additional frequencies produced when two different frequencies are combined. One beat frequency is the sum of the two original frequencies; the other is the difference between them.

beat-frequency oscillator — Abbreviated bfo. An oscillator that produces a signal which mixes with another signal to provide frequencies equal to the sum and difference of the combined frequencies.

beating—The combining of two or more frequencies to produce sum and difference frequencies called beats.

beating-in—Interconnecting two transmitter oscillators and adjusting one until no beat frequency is heard in a connected receiver. The oscillators are then at the same frequency.

beating oscillator—*See* Local Oscillator.

beat note—The wave of difference frequency created when two waves of different frequencies are combined. The beat note is equal to the difference in frequency between the two.

beat reception—*See* Heterodyne Reception.

beats—Beat notes which are generally at a sufficiently low audio frequency that they can be counted.

beat tone—Musical tone due to beats, produced by the heterodyning of two high-frequency wave trains.

beaver tail—A fan-shaped radar beam, wide in the horizontal plane and narrow in the vertical plane. The beaver tail is swept up and down for height finding.

bedspring—A broadside antenna array with a flat reflector.

before start—The interval before the starting circuit to a timer has been operated. The timer is fully reset and all contacts are in the precycle position.

bel—The fundamental unit in a logarithmic scale for expressing the ratio of two amounts of power. The number of bels is equal to the $\log_{10} P_1/P_2$, where P_1 is the power level being considered and P_2 is an arbitrary reference level. The decibel, equal to 1/10 bel, is a more commonly used unit.

B eliminator—A power pack that changes the a-c power-line voltage to the d-c source required by the vacuum tubes. In this way, batteries can be eliminated.

bell—An electrical device consisting of a hammer vibrated by an electromagnet. The hammer strikes the sides of the bell and emits a ringing noise. The electromagnet attracts an armature or piece of soft iron forming part of the hammer lever. A contact breaker then opens the circuit and cuts off the attraction. A spring draws the hammer back to its original position, closing the circuit and repeating the action.

Bellini-Tosi direction finder—An early radio direction-finder system consisting of two loop antennas at right angles to each other and connected to a goniometer.

bellows—A pressure-sensing element consisting of a ridged metal cylinder closed at one end. A pressure difference between its outside and inside will cause the cylinder to expand or contract along its axis.

bellows contact—A contact in which a multileaf spring is folded. This type provides a more uniform spring rate over the full tolerance range of the mating unit.

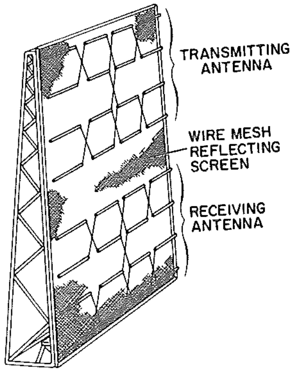
bell transformer—A small iron-core transformer; its primary coil is connected to an a-c primary line, and its secondary coil delivers 10 to 20 volts for operation of a doorbell, buzzer, or chimes.

bell wire—Cotton-covered copper wire, usually No. 18, used for doorbell and thermostat connections in homes and for similar low-voltage work.

bend—A change in the direction of the longitudinal axis of a waveguide.

bend waveguide—A section of waveguide in which the direction of the longitudinal axis is changed.

Benito—A c-w navigational system in which the distance to an aircraft is determined on the ground by measuring the phase difference of an audio signal transmitted from the ground and retransmitted by the aircraft. Bearing information is obtained by ground direction finding of the aircraft signals.



Bedspring antenna.

beta—Symbolized by the Greek letter *beta* (β). Also called current-transfer ratio. 1. The current transfer ratio (gain) of a transistor in the common-emitter circuit arrangement. This is the ratio of a-c collector current to a-c base current. 2. A symbol used to denote B quartz.

beta circuit—In a feedback amplifier, the circuit which transmits a portion of the amplifier output back to the input.

beta cutoff frequency — The frequency at which the beta of a transistor is 3 decibels below the low-frequency value.

beta particle—A small electrically charged particle thrown off by many radioactive materials. It is identical to the electron and possesses the smallest negative electrical charge found in nature. Beta particles emerge from radioactive material at high speeds, sometimes close to the speed of light.

beta ray—A stream of beta particles.

betatron—A large doughnut-shaped accelerator which produces artificial beta radiation. Electrons (beta particles) are whirled through a changing magnetic field. They gain speed with each trip and emerge with high energies (on the order of 100 million electron volts in some instances).

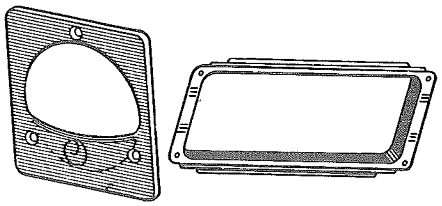
bev—A Billion Electron Volts. An electron possessing this much energy travels at a speed close to that of light—186,000 miles a second.

bevatron—A very large circular accelerator in which protons are whirled between the poles of a huge magnet to produce energies in excess of 1 billion electron volts.

Beverage antenna—*See* Wave Antenna.

beyond-the-horizon propagation—*See* Scatter Propagation.

beyond-the-horizon transmission—*See* Scatter Propagation.



Bezel.

bezel—1. A holder designed to receive and position the edges of a lens, meter, window, or dial glass. 2. The flange or cover used for holding an external graticule or crt cover in front of the crt in an oscilloscope. May also be used for mounting a trace-recording camera or other accessory item.

bfo—Abbreviation for beat-frequency oscillator.

B-H curve—Curve plotted on a graph to show successive states during magnetization of a ferromagnetic material. A normal magnetization curve is a portion of a symmetrical hysteresis loop. A virgin magnetization curve shows what happens the first time the material is magnetized.

B-H meter—A device for measuring the intrinsic hysteresis loop of a sample of magnetic material.

bias—1. The electrical, mechanical, or magnetic force applied to a relay, vacuum tube, or other device for the purpose of establishing an electrical or mechanical reference level for the operation of the device. 2. Direct-current potential applied to the control grid of a vacuum tube. 3. Bias derived from a direct current, used on signaling or telegraph relays or electromagnets to secure the desired time spacing of transitions from marking to spacing. 4. A method of restraining a relay armature, by means of spring tension, to secure a desired time spacing of transitions from marking to spacing. 5. The average direct-current voltage between the control grid and cathode of a vacuum tube. 6. The effect on teletypewriter signals produced by the electrical characteristics of the line and the equipment. 7. Energy applied to a relay to hold it in a given position.

bias cell—A dry cell used in the grid circuit of a vacuum tube to provide the necessary C-bias voltage.

bias current—The current through the base-emitter junction of a transistor. It is adjusted to set the operating point of the transistor.

bias distortion—1. Distortion resulting from operation on a nonlinear portion of the characteristic curve of a vacuum tube or other device, due to improper biasing. 2. In teletype circuits, the uniform shifting of mark pulses from their proper position in relationship to the start pulses.

biased induction—Symbolized by B_b. The biased induction at a point in a magnetic material which is subjected simultaneously to a periodically varying magnetizing force and a biasing magnetizing force and is the algebraic mean of the maximum and minimum values of the magnetic induction at the point.

bias-induced noise—The difference between bulk-erased and zero-modulation noise.

biasing magnetizing force—Symbolized by H_b. A biasing magnetizing force at a point in a magnetic material which is subjected simultaneously to a periodically varying magnetizing force and a constant magnetizing force and is the algebraic mean of the maximum and minimum values of the combined magnetizing forces.

bias meter—Used in teletypewriter work for measuring signal bias directly in percent. A positive reading on the meter indicates a marking-signal bias; a negative reading indicates a spacing-signal bias.

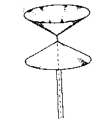
bias oscillator—An oscillator used in magnetic recorders to generate an a-c signal in the range of 40 to 80 kHz for the purpose of magnetic biasing to obtain a linear recording characteristic. Usually the bias oscillator also serves as the erase oscillator.

bias resistor—A resistance connected into a self-biasing vacuum-tube circuit to produce the voltage drop necessary to provide a desired biasing voltage.

bias-set frequency—In direct magnetic tape recording, a specified recording frequency employed during the adjustment of bias level for optimum record performance (not the frequency of the bias).

bias telegraph distortion — Distortion in which all mark pulses are lengthened (positive bias) or shortened (negative bias). It can be measured with a steady stream of "unbiased reversals" (square waves having equal-length mark and space pulses). The average lengthening or shortening does not give true bias distortion unless other types of distortion are negligible.

bias windings—Control windings of a saturable reactor, by means of which the operating condition is translated by an arbitrary amount.



Biconical antenna.

biconical antenna—An antenna which is formed by two conical conductors, having a common axis and vertex, and excited at the vertex. When the vertex angle of one of the cones is 180°, the antenna is called a discone.

bidirectional—Responsive in opposite directions. An ordinary loop antenna is bidirectional because it has maximum response from the opposite directions in the plane of the loop.

bidirectional antenna—An antenna having two directions of maximum response.

bidirectional current—A current which is both positive and negative.

bidirectional microphone—A microphone in which the response predominates for sound incidences of 0° and 180°.

bidirectional pulses—Pulses, some of which rise in one direction and the remainder in the other direction.

bidirectional pulse train—A pulse train, some pulses of which rise in one direction and the remainder in the other direction.

bidirectional transducer — *See* Bilateral Transducer.

bidirectional transistor—A transistor which is specified with parameter limits in both the normal and inverted configuration and has substantially the same electrical characteristics when the terminals normally designed as emitter and collector are interchanged.

bifilar resistor — A resistor wound with a wire doubled back on itself to reduce the inductance.

bifilar transformer—A transformer in which the turns of the primary and secondary windings are wound together side-by-side and in the same direction. This type of winding results in near unity coupling, so that there is a very efficient transfer of energy from primary to secondary.

bifilar winding—A method of winding noninductive resistors in which the wire is folded back on itself and then wound double, with the winding starting from the point at which the wire is folded.

bifurcated contact — A movable contact which is forked (divided) to provide two contact-mating surfaces in parallel for a more reliable contact.

bilateral amplifier—An amplifier capable of receiving as well as transmitting signals; it is used primarily in transceivers.

bilateral antenna—An antenna, such as a loop, having maximum response in exactly opposite directions (180° apart).

bilateral bearing—A bearing which indicates two possible directions of wave arrival. One of these is the true bearing, and the other is a bearing displaced 180° from the true bearing.

bilateral circuit — A circuit wherein equipment at opposite ends is managed, operated, and maintained by different services.

bilateral element—A two-terminal element, the voltage-current characteristic of which has odd symmetry around the origin.

bilateral network—A network in which a given current flow in either direction results in the same voltage drop.

bilateral transducer — Also called bidirectional transducer. A transducer capable of transmission simultaneously in both directions between at least two terminations.

billboard antenna—Broadside array consisting of stacked dipoles with flat reflectors.

bimag—*See* Tape-wound Core.

bimetallic strip—A strip formed of two dissimilar metals welded together. Because the metals have different temperature coefficients of expansion, the strip bends or curls when the temperature changes.

bimetallic thermometer—A device containing a bimetallic strip which expands or contracts as the temperature changes. A calibrated scale indicates the amount of change in temperature.

bimorph cell—Two crystal elements (usually Rochelle salt) in rigid combination, arranged to act as a mechanical transformer in headphones, microphones, pickups, and speakers.

binary—1. A numbering system using a base number, or radix, of 2. In the binary system, there are only two digits—1 and 0. 2. Pertaining to a characteristic or property involving a selection, choice, or condition in which there are two possibilities. 3. Another range for bistable multivibrator.

binary cell—In an electronic computer, an elementary unit of storage which can be placed in either of two stable states.

binary chain — A series of binary circuits, each of which can exist in either one of two states, arranged so each circuit can affect or modify the condition of the next circuit.

binary channel—A transmission facility limited to the use of two symbols.

binary code—A code in which each code element is one of two distinct kinds or values—for example, the presence and absence of a pulse.

binary-coded—Expressed by a series of binary digits (0's and 1's).

binary-coded character—A decimal digit, alphabetic letter, punctuation mark, etc., represented by a fixed number of consecutive binary digits.

binary-coded decimal—Abbreviated BCD. A system of number representation in which each decimal digit of a number is expressed by binary numbers.

binary-coded digit—One element of a notation system for representing a decimal digit by a fixed number of binary positions.

binary-coded octal system—An octal numbering system in which each octal digit is represented by a three-place binary number.

binary counter—*See* Binary Scaler.

binary digit—*See* Bit.

binary magnetic core—A ring-shaped magnetic material which can be made to take either of two stable states of magnetic polarization.

binary notation—*See* Binary Number System.

binary number system—A number system using two symbols (usually denoted 0 and 1) and having 2 as its base, just as the decimal system uses 10 symbols (0, 1, . . . , 9) and has a base of 10. Also called binary notation.

binary numeral—The binary representation of a number—e.g., "101" is the binary numeral and "V" is the Roman numeral of the number of fingers on one hand.

binary point—The point which marks the place between integral powers of two and fractional powers of two in a binary number.

binary pulse-code modulation—A form of pulse-code modulation in which the code for each element of information consists of one of two distinct kinds, e.g., pulses and spaces.

binary scaler—Also called binary counter. 1. A counter which produces one output pulse for every two input pulses. 2. A counting circuit, each stage of which has two distinguishable states.

binary search—Also called dichotomizing search. A search in which a set of items is divided into two parts; one part is rejected, and the process is repeated on the accepted part until those items with the desired property are found.

binary signaling—A communications mode in which information is passed by the presence and absence, or plus and minus variations, of one parameter of the signaling medium.

binary system—A system of mathematical computation based on powers of 2.

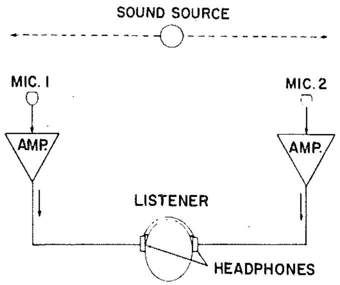
binary-to-decimal conversion—The process of converting a number written in binary notation to the equivalent number written in the ordinary decimal notation.

binaural—Two-eared; applied to a kind of recording that is played into separate headphones to create a sense of depth.

binaural disc—A stereo record with two separate signals, one on each wall of its recorded grooves. Stereophonic sound is obtained by feeding each signal into its own speaker.

binaural effect—The effect which makes it possible for a person to distinguish the difference in arrival time or intensity of sound at his ears and thereby determine the direction from which a sound is arriving.

binaural recorder—A tape recorder which employs two separate recording channels, or systems, each with its own microphone, amplifier, recording and playback heads, and earphones. Recordings using both channels are made simultaneously on a single magnetic tape having two parallel tracks. During playback, the original sound is reproduced with a depth and realism unequalled by any other recording method. For a true binaural effect, headphones are necessary.

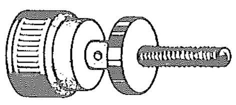


Binaural sound reproducing system.

binaural sound—Sound recorded or transmitted by pairs of equipment so as to give the listener the effect of having heard the original sound.

binder—A substance, like cement, used to hold particles together and thus provide mechanical strength in carbon resistors and phonograph records.

binding energy—The minimum energy required to dissociate a nucleus into its component neutrons and protons. Neutron or proton binding energies are those energies required to remove a neutron or a proton, respectively, from a nucleus. Electron binding energy is that energy required to remove an electron from an atom or a molecule.



Binding post.

binding post—A bolt-and-nut terminal for making temporary electrical connections.

binistor—A four-terminal controlled rectifier semiconductor which provides bistable, negative-resistance characteristics.

binomial array—A directional antenna array used for reducing minor lobes and providing maximum response in opposite directions.

biochemical fuel cell—An electrochemical generator of electrical power in which bi-organic matter is used as the fuel source. In the usual electrochemical reaction, air serves as the oxidant at the cathode and microorganisms are used to catalyze the oxidation of the bi-organic matter at the anode.

bioelectrogenesis—The practical application of electricity drawn directly from the bodies of animals, including humans, to power electronic devices and appliances.

bioelectronics—The application of electronic theories and techniques to the problems of biology.

biological shield—A mass of absorbing material placed around a reactor or radioactive source to reduce the radiation to a level that is safe for human beings.

biometrics—The science of statistics as applied to biological observations.

bionics—1. The science of applying biological techniques to the design of electronic devices and systems. 2. The science of systems which function in a manner resembling living systems.

biotelemetry—The technique of measuring or monitoring vital processes and transmitting data without wires to a point (or points) remote from the subject.

biotelescanner—A device that can analyze and radio data on life forms during space exploration.

bipolar—Having two poles.

bipolar electrode—An electrode without metallic connection with the current supply, one face of which acts as an anode surface and the opposite face as a cathode surface when an electric current is passed through a cell.

bipolar magnetic driving unit—A headphone or speaker unit having two magnetic poles acting directly on a flexible iron diaphragm.

bipolar transistor—A transistor that uses both negative and positive charge carriers.

biquinary notation—A numerical system of notation based on a double scale of five.

biscuit—*See* Preform.

bistable—1. A circuit element with two stable operating states—e.g., a flip-flop in which one transistor is saturated while the other is turned off. It changes state for each input pulse or trigger. 2. A device capable of assuming either one of two stable states.

bistable multivibrator (flip-flop)—A circuit having two stable states; it will stay in either one indefinitely until appropriately triggered after which it immediately switches to the other state.

bistable relay—A relay that requires two pulses to complete one cycle composed of two conditions of operation. Also called locked, interlocked, and latching relay.

biswitch—A two-terminal integrated device which basically performs the function of two PNPN switches interconnected so as to provide bilateral switching.

bit—Abbreviation for binary digit. A unit of information equal to one binary decision, or the designation of one of two possible and equally likely values or states (such as 1 or 0) of anything used to store or convey information. It may also mean "yes" or "no."

bit density—The number of bits of information contained in a given area, such as the number of bits written along an inch of magnetic tape.

bit rate—The speed of transmission of bits.

black—A signal produced at any point in a facsimile system by the scanning of a selected area of subject copy having maximum density.

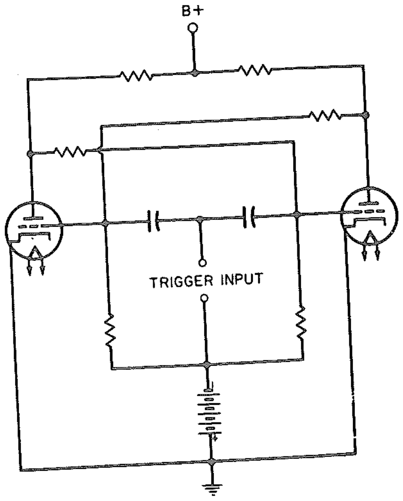
black and white—*See* Monochrome.

black and white transmission—*See* Monochrome Transmission.

black area—An area with encrypted signal only present.

black-body—1. An idealized emitter for which total radiated energy and the spectral distribution of the energy are accurately known functions of temperature. These relationships are given by Planck's law. 2. A solid that radiates or absorbs energy with no internal reflection of the energy at any wavelength. Physically it may be a hollow sphere coated on the inside with lampblack and with an opening through which energy may enter or leave.

black box—1. A term used loosely to refer to any subcomponent that is equipped with connects and disconnects so that it can be readily inserted into or removed from a specified place in a larger system (e.g., the complete missile or some major subdivision) without benefit of knowledge of its detailed



Bistable multivibrator.

internal structure. 2. A term pertaining to either the functional transformation that acts upon a specified input to give a particular output or to the apparatus for accomplishing this transformation (without regard to the detailed circuitry used). 3. A useful mathematical approach to an electronic circuit which concerns itself only with the input and output, and ignores the interior elements, discrete or integrated.

black compression—Also called black saturation. The reduction in the gain of a television picture signal at those levels corresponding to dark areas in the picture with respect to the gain at that level corresponding to the midrange light value in the picture. The over-all effect of black compression is to reduce contrast in the low lights of the picture.

blacker-than-black—The amplitude region of the composite video signal below the reference black level in the direction of the synchronizing pulses.

blacker-than-black level—A voltage value used in an electronic television system for control impulses. It is greater than the value representing the black portions of the image.

black level—That level of the picture signal corresponding to the maximum limit of black peaks.

black light—Invisible light radiation. May be either ultraviolet or infrared radiation, both of which are invisible.

black-light emitter—A source of electromagnetic radiation in the ultraviolet or infrared region, just outside the visible spectrum.

black peak—A peak excursion of the picture signal in the black direction.

black saturation—*See* Black Compression.

black signal—Also called picture black. A signal produced at any point in a facsimile system by the scanning of a maximum-density area of the subject copy.

blackout—1. Interruption of radiocommunication due to excess absorption caused by solar flares. During severe blackouts, all frequencies above approximately 1500 kHz are absorbed excessively in the daylight zone. 2. Passive defense that consists of interrupting all forms of communication or identification.

black transmission—1. In an amplitude-modulation facsimile system a form of transmission in which the maximum transmitted power corresponds to the maximum density of the copy. 2. In a frequency-modulation system, a form of transmission, in which the lowest transmitted frequency corresponds to the maximum density of the copy.

blank—1. The result of the final operation on a crystal. 2. To cut off the electron beam of a cathode-ray tube. 3. A code character to denote the presence of no information rather than the absence of information. In the Baudot code, it is composed of all spacing pulses. In paper tape, it is represented by a feedhole without intelligence holes.

blanked picture signal—The signal resulting from adding blanking to a picture signal. Adding the sync signal to the blanked picture signal forms the composite picture signal.

blanketing—The overriding of a signal by a more powerful one or by interference, so that a receiver is unable to receive the desired signal.

blank groove—*See* Unmodulated Groove.

blanking—The process of making a channel or device noneffective for the desired interval. In television, blanking is the substitution for the picture signal, during prescribed intervals, of a signal the instantaneous amplitude of which is such as to make the return trace invisible. *See also* Gating.

blanking level—Also called pedestal level. In a composite picture signal, the level that separates the range of the composite picture signal containing picture information from the range containing synchronizing information.

blanking pulse—A square wave (positive or negative) used to switch off electronically a part of a television or radar set for a predetermined length of time.

blanking signal—A wave made up of recurrent pulses related in time to the scanning process and used to effect blanking. In television, this signal is composed of pulses at line and field frequencies, which usually originate in a central sync generator and are combined with the picture signal at the pickup equipment in order to form the blanked picture signal. The addition of a sync signal completes the composite picture signal.

blanking time—The length of time the electron beam of a cathode-ray tube is cut off.

blanking zone—*See* Blanking Pulse.

blank tape—*See* Raw Tape.

blasting—Overloading of an amplifier or speaker, resulting in severe distortion of loud sounds.

bleeder current—The current drawn continuously from a power supply by a resistor. Used to improve the voltage regulation of the power supply.

bleeder resistor—1. A resistor used to draw a fixed current. Also used, as a safety measure, to discharge a filter capacitor after the circuit is de-energized. 2. A resistor placed in the power supply of a radio receiver or other electronic device to stabilize the voltage supply.

bleeding whites—An overloading condition in which white areas in a television picture appear to flow into the black areas.

blemish—On the storage surface of a charge-storage tube, an imperfection which produces a spurious output.

blind approach—An aircraft landing approach when visibility is poor, usually made with the aid of instruments and radiocommunication.

blind zone—An area from which echoes cannot be received; generally, an area shielded from the transmitter by some natural obstruction and therefore from which there can be no return.

blip—Sometimes referred to as pip. On a cathode-ray display, a spot of light or a base-line irregularity representing the radar reflection from an object.

blip-scan ratio—The ratio between a single recognizable blip on a radar scope and the number of scans necessary to produce it. The blip-scan ratio of any given radar set varies with the range, antenna tilt, level of operator and set performance, target aspect, wind, etc.

blivet—*See* Land.

Bloch wall—The transition layer separating adjacent ferromagnetic domains.

block—A set of things, such as words, characters, or digits, handled as a unit by a computer.

block diagram—A diagram in which the essential units of any system are drawn in the form of blocks, and their relationship to each other is indicated by appropriately connected lines. The path of the signal or energy may be indicated by lines and/or arrows.

blocked impedance—The input impedance of a transducer when its output is connected to a load of infinite impedance.

blockette—In digital computer programming, a subgroup, or subdivision, of a group of consecutive machine words transferred as a unit.

block-grid keying—A method of keying a continuous-wave transmitter by operating the amplifier stage as an electronic switch. During the spacing interval when the key is open, the bias on the control grid becomes highly negative and prevents the flow of plate current so that the tube has no output. During the marking interval when the key is closed, this bias is removed and full plate current flows.

blocking—Application of an extremely high bias voltage to a transistor, vacuum tube, or metallic rectifier to prevent current from flowing in the forward direction.

blocking capacitor—A capacitor which introduces a comparatively high series impedance for limiting the flow of low-frequency alternating or direct current without materially affecting the flow of high-frequency alternating current.

blocking layer—*See* Depletion Layer.

blocking oscillator—Also called squegging oscillator. An electron-tube oscillator that operates intermittently as its grid bias increases during oscillation to a point where the oscillations stop, and then decreases until oscillation resumes.

blocking-oscillator driver—A circuit which develops a square pulse used to drive the modulator tubes, and which usually contains a line-controlled blocking oscillator that shapes the pulse into the square wave.

blocking relay—A device which initiates a pilot signal to block tripping on external faults in a transmission line or in other apparatus under predetermined conditions, or which co-operates with other devices to block tripping or to block reclosing on an out-of-step condition or on power swings.

block protector—A rectangular piece of carbon, *Bakelite* with a metal insert, or porcelain with a carbon insert which, in combination with each other, make one element of a protector. They form a gap which will break down and provide a path to ground for excessive voltages.

block sort—A computer sorting technique in which the file is first divided according to the most significant character of the key, and the separate portions are then sorted one at a time. It is used particularly for large files.

blooming—An increase in the size of the scanning spot on a cathode-ray tube, caused by defocusing when the brightness control is set too high. The result is expansion and consequent distortion of the image. May also be caused by insufficient high voltage.

blow—The opening of a circuit because of excessive current, particularly when the current is heavy and a melting or breakdown point is reached.

blower—An electric fan used to supply moving air for cooling purposes.

blown jacket—The common term given to an outer covering of insulation of a cable that was applied by the controlled inflation of the cured jacket tube and the pulling of the cable through it.

blowout coil—An electromagnetic device used to establish a magnetic field in the space where an electrical circuit is broken and thus displace and extinguish the arc.

blowout magnet—A strong permanent magnet or electromagnet used for reducing or deflecting the arc between electrodes or contacts.

blue-beam magnet—A small permanent magnet used to adjust the static convergence of the electron beam for blue phosphor dots in a three-gun color picture tube.

blue glow—The glow normally seen in vacuum tubes containing mercury vapor; it is due to ionization of the molecules of mercury vapor.

blue gun—In a three-gun, color picture tube, the electron gun whose beam strikes the phosphor dots emitting the blue primary color.

blue restorer—The d-c restorer in the blue channel of a three-gun color-television picture-tube circuit.

blue video voltage—The signal voltage that controls the grid of the blue gun in a three-gun picture tube. This signal is a reproduction of the blue output signal of the color-tv camera.

bobbin—A small insulated spool which serves as a support for a coil or wirewound resistor.

bobbin core—*See* Tape-wound Core.

body capacitance — Capacitance introduced into an electrical circuit by the proximity of the human body.

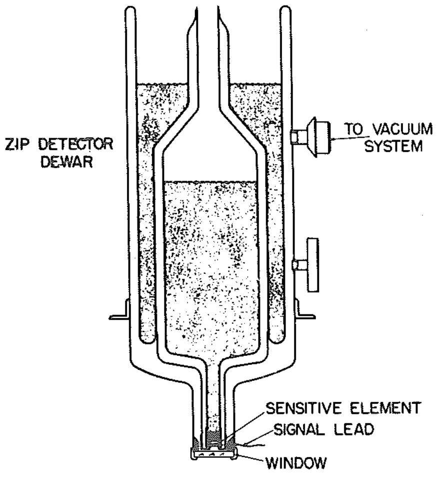
body electrodes—Electrodes placed on or in the body to couple electrical impulses from the body to an external measuring or recording device.

boffle — A speaker enclosure, developed by H. A. Hartley, containing a group of stretched, resilient sound-absorbing screens.

bogey—The average, or published, value for a tube characteristic. A bogey tube would be one having all characteristics of a bogey value.

bogey electron device—An electron device the characteristics of which have the published nominal values for the type.

boiling point—The temperature at which a liquid vaporizes when heated. The exact point depends on the absolute pressure at the liquid-vapor surface.



Superconducting bolometer.

bolometer—A radiation detector that converts incident radiation into heat which, in turn, causes a temperature change in the material used in the detector. This change is then measured to give an indication of the amount of incident radiant energy.

bolted fault level—*See* Adjusted Circuit.

bombardment — 1. The directing of high-speed electrons at an electrode, causing secondary emission of electrons, fluorescence, disintegration, or the production of X rays. 2. The process of directing high-speed particles at atoms to cause ionization or transmutation.

bond—1. Electrical interconnection made with a low-resistance material between a chassis, metal shield cans, or cable shielding braid, in order to eliminate undesirable interaction and interference resulting from high-impedance paths between them. 2. *See* Valence Bond.

bonded assembly—An assembly, the supporting frame and metallic noncircuit elements of which are connected so as to be electrically shorted together.

bonded-barrier transistor — A transistor made by alloying the base with the alloying material on the end of a wire.

bonded NR diode—An N junction semiconductor device in which the negative resistance arises from a combination of avalanche breakdown and conductivity modulation due to the current through the junction.

bonded pickup—*See* Bonded Transducer.

bonded strain gage—A pressure transducer that uses a pressure-sensing system consisting of strain-gage elements firmly bonded to a pressure-responsive member. Thermal stability and insensitivity to shock and vibration are improved by means of this bonded construction.

bonded transducer—Also called bonded pickup. A transducer which employs the bonded strain-gage principle of transduction.

bonding—1. Soldering or welding together various elements, shields, or housings of a device to prevent potential differences and possible interference. 2. A method used to produce good electrical contact between metallic parts of any device. Used extensively in automobile and aircraft to prevent static buildup. Also refers to the connectors and straps used to bond equipment. 3. The means employed to obtain an electromagnetically homogenous mass having an equipotential surface.

bonding conductor—A conductor which serves to connect exposed metal surfaces together.

bond strength—A measure of the amount of stress required to separate a layer of material from the base to which it is bonded. Peel strength, measured in pounds per inch of width, is obtained by peeling the layer; pull strength, measured in pounds per square inch is obtained by a perpendicular pull applied to a surface of the layer.

bone conduction — The process by which sound is conducted to the inner ear through the cranial bones.

book capacitor—A two-plate trimmer capacitor that has its plates hinged together like the pages of a book. The capacitance is varied by changing the angle between the plates.

Boolean algebra—A system of mathematical logic dealing with classes, propositions, on-off circuit elements, etc. Associated by operators as AND, OR, NOT, EXCEPT, IF . . . THEN, etc., thereby permitting computations and demonstration as in any mathematical system. Named after George Boole, famous English mathematician and logician, who introduced it in 1847.

Boolean calculus—Boolean algebra modified to include time.

Boolean function—A mathematical function in Boolean algebra.

boom—A mechanical support for a microphone, used in a television studio to suspend the microphone within range of the actors' voices, but out of camera range.

boost capacitor — A capacitor used in the damper circuit of a television receiver to supply a boosted B voltage.

boost charge—The partial charge of a storage battery, usually at a high current rate for a short period.

boosted B voltage — In television receivers the voltage resulting from the combination of the B-plus voltage from the power supply and the average value of voltage pulses coming through the damper tube from the horizontal deflection-coil circuit. The pulses are partially or wholly smoothed by filtering. This boosted voltage may be several hundred volts higher than the B-plus voltage.

booster — 1. A carrier-frequency amplifier, usually a self-contained unit, connected between the antenna or transmission line and a television or radio receiver. 2. An intermediate radio or tv station which retransmits signals from one fixed station to another. 3. A small, self-contained transformer designed to be connected to a cathode-ray tube socket to increase the filament voltage and thereby extend the life of the tube.

booster amplifier—A circuit used to increase the output current or the voltage capabilities of an operational amplifier circuit without loss of accuracy (ideally) or inversion of polarity. Usually applied inside the loop for accuracy.

booster voltage—The additional voltage supplied by the damper tube of a television receiver to the horizontal-output, horizontal-oscillator, and vertical-output tubes, resulting in a greater sawtooth sweep output.

boot—1. A form placed around the wire termination of a multiple-contact connector for the purpose of containing the liquid potting compound until it hardens. 2. A protective housing, usually made from a resilient material, used to protect connector or other terminals from moisture.

bootstrap circuit—A single-stage amplifier in which the output load is connected between the negative end of the plate supply and the cathode, the signal voltage being applied between the grid and cathode. The name "bootstrap" arises from the fact that the change in grid voltage also changes the potential of the input source (with respect to ground) by an amount equal to the output signal.

boresight error—The angular deviation of the electrical boresight of an antenna from its reference boresight.

boss—*See* Land.

bottom metalization — The metalization which may be provided over the back portion of an uncased IC chip facilitating its face-up attachment.

bounce—An unnatural, sudden variation in the brightness of a television picture.

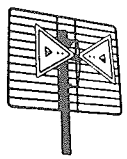
boundary—An interface between P and N material at which donor and acceptor concentrations are equal.

boundary defect—In a crystal, the boundary area between two adjacent perfect crystal regions that are tilted slightly with respect to each other.

bound charge—On a conductor, the charge which, owing to the inductive action of a neighboring charge, will not escape to ground; residual charge.

bound circuit — A circuit designed to limit the excursion of a signal. The limit value it establishes may be nominal when used for protection, or highly precise when used operationally.

bound electron—An electron bound to the nucleus of an atom by electrostatic attraction.



Bow-tie antenna.

bow-tie antenna—An antenna generally used for uhf reception. It consists of two triangles in the same plane, with a reflector behind them. The transmission line is connected to the points which form a gap.

boxcar circuit—A circuit used in radar to sample voltage waveforms and store the latest value sampled.

boxcar lengthener—A circuit that lengthens a series of pulses without changing their heights.

boxcars—Long pulses that are separated by very short spaces.

B power supply—A power supply which provides the plate and screen voltages applied to a vacuum tube.

B-quad—A quad arrangement similar to the S-quad except for a short between the junctions of the two sets of series elements. Also called bridge quad or bar quad.

Bragg's law—An expression of the conditions under which a system of parallel atomic layers in a crystal will reflect an X-ray beam with maximum intensity.

braid—1. A weave of organic or inorganic fiber used as a covering for a conductor or group of conductors. 2. A woven metal tube used as shielding around a conductor or group of conductors. When flattened, it is used as a grounding strap.

braided wire—A flexible wire made up of small strands woven together.

brain waves—The patterns of lines produced on the moving chart of an electroencephalograph as the result of electrical potentials produced by the brain, picked up by electrodes, and amplified in the machine.

braking magnet—*See* Retarding Magnet.

branch—1. In an electronic network, a section between two adjacent branch points. 2. A portion of a network consisting of one or more two-terminal elements in series.

branch circuit—In a wiring system, that portion extending beyond the final overcurrent device protecting the circuit.

branch current—The current in the branch of a network.

branch impedance—In a passive branch, the impedance obtained by assuming a driving force across and a corresponding response in the branch, no other branch being electrically connected to the one under consideration.

branching—In a computer, a method of selecting, on the basis of the computer results, the next operation to execute while the program is in progress.

branch order—An instruction used to link subroutines into the main program of a computer.

branch point—1. In an electric network, the junction of more than two conductors. *(Also see* Node.) 2. In a computer, a point in the routine where one of two or more choices is selected under control of a routine.

branch voltage—The voltage across a branch of a network.

brass pounder—Amateur term for a Morse code operator, especially one who spends long hours handling "traffic."

breadboard construction—An arrangement in which electronic components are fastened temporarily to a board for experimental work.

breadboard model — An assembly in rough form to prove the feasibility of a circuit, device, system, or principle.

break—1. An open circuit. 2. An interruption in radio transmission to permit transmission from the other end.

break-before-make contacts — Contacts which interrupt one circuit before establishing another.

break contact — In a switching device, the contact which opens a circuit upon operation of the device (normally closed contact).

breakdown—1. An electric discharge through an insulator, insulation on wire, or other circuit separator, or between electrodes in a vacuum or gas-filled tube. 2. The phenomenon occurring in a reverse-biased semiconductor diode. The start of the phenomenon is observed as a transition from a region of high dynamic resistance to one of substantially lower dynamic resistance. This is done to boost the reverse current.

breakdown diode—*See* Avalanche Diode.

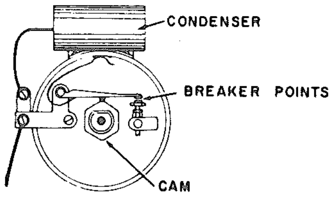
breakdown impedance—Also called avalanche impedance. The small-signal impedance at a specified direct current in the breakdown region of a semiconductor diode.

breakdown region—The entire region of the volt-ampere characteristic beyond the initiation of breakdown due to reverse current in a semiconductor-diode characteristic curve.

breakdown strength—*See* Dielectric Strength.

breakdown torque—The maximum torque a motor will develop, without an abrupt drop in speed, as the rated voltage is applied at the rated frequency.

breakdown voltage — 1. That voltage at which an insulator or dielectric ruptures, or at which ionization and conduction take place in a gas or a vapor. 2. The voltage measured at a specified current in the breakdown region of a semiconductor diode. Also called zener voltage. 3. The voltage required to jump an air gap.



Breaker points.

breaker points — The low-voltage contacts that interrupt the current in the primary circuit of the ignition system of a gasoline engine.

break frequency—In a plot of log gain (attenuation) versus log frequency, the frequency at which the asymptotes of two adjacent linear slope segments meet.

break-in keying—In the operation of a radiotelegraph communication system, a method by which the receiver is capable of receiving signals during transmission spacing intervals.

break-in operation—A method of radiocommunication involving break-in keying which allows the receiving operator to interrupt the transmission.

break-in relay — A relay used for break-in operation.

break-make contact — Also called transfer contact. A contact form in which one contact opens its connection to another contact and then closes its connection to a third contact.

breakout—The exit point of a conductor or number of conductors along various points of a main cable of which the conductors are a part. This point is usually harnessed or sealed with some synthetic-rubber compound.

breakover voltage — The value of positive anode voltage at which an scr with the gate circuit open switches into the conductive state.

breakpoint—A place in a routine specified by an instruction, instruction digit, or other condition, where the routine may be interrupted by external intervention or by a monitor routine.

breakpoint instruction — In the programming of a digital computer an instruction which, together with a manual control, causes the computer to stop.

breakpoint switch — A manually operated switch which controls conditional operation at breakpoints; it is used primarily in debugging.

breakup—*See* Color Breakup.

breathing—Amplitude variations similar to "bounce," but at a slow, regular rate.

breezeway—In the NTSC color system, that portion of the back porch between the trailing edge of the sync pulse and the start of the color burst.

B-register—A computer register that stores a word which will change an instruction before the computer carries out that instruction.

bremsstrahlung — Electromagnetic radiation emitted by a fast-moving charged particle (usually an electron) when it is slowed down (or accelerated) and deflected by the electric field surrounding a positively charged atomic nucleus. X rays produced in ordinary X-ray machines are bremsstrahlung. (In German, the term means "braking radiation.")

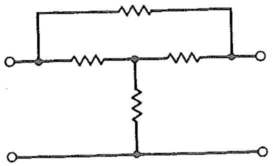
brevity code—A code which has as its sole purpose the shortening of messages rather than the concealment of their content.

Brewster angle—The angle of incidence at which the reflection of parallel-polarized electromagnetic radiation at the interface between two dielectric media equals zero.

bridge—1. In a measuring system, an instrument in which part or all of a bridge circuit is used to measure one or more electrical quantities. 2. In a fully electronic stringed instrument, the part that converts the mechanical vibrations produced by the strings into electrical signals.

bridge circuit—A network arranged so that, when an electromotive force is present in one branch, the response of a suitable detecting device in another branch may be zeroed by suitable adjustment of the electrical constants of still other branches.

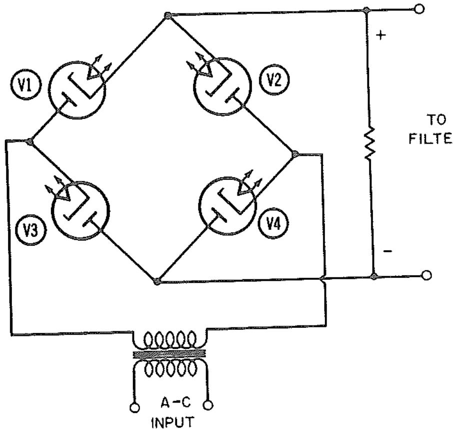
bridged tap—The portion of a cable pair connected to a circuit which is not a part of the useful path.



Bridged-T network.

bridged-T network—A T-network in which the two series impedances of the T are bridged by a fourth impedance.

bridge duplex system — A duplex system based on the Wheatstone-bridge principle in which a substantial neutrality of the receiving apparatus to the transmitted currents is obtained by an impedance balance. Received currents pass through the receiving relay, which is bridged between the points that are equipotential for the transmitted currents.



Bridge rectifier.

bridge hybrid—*See* Hybrid Junction

bridge quad—*See* B-quad.

bridge rectifier—A full-wave rectifier with four elements connected in the form of a bridge circuit so that d-c voltage is obtained from one pair of opposite junctions when an alternating voltage is applied to the other pair of junctions.

bridge transformer—*See* Bridging Transformer.

bridging—The shunting of one electrical circuit by another.

bridging amplifier—An amplifier with an input impedance sufficiently high that its input may be bridged across a circuit without substantially affecting the signal level of the circuit.

bridging connection—A parallel connection by means of which some of the signal energy in a circuit may be withdrawn with imperceptible effect on the normal operation of the circuit.

bridging contacts—A set of contacts in which the moving contact touches two stationary contacts simultaneously during transfer.

bridging gain—Ratio between the power a transducer delivers to a specified load impedance under specified operating conditions, and the power dissipated in the reference impedance across which the transducer input is bridged. Usually expressed in decibels.

bridging loss—Ratio between the power dissipated in the reference impedance across which the input of a transducer is bridged, and the power the transducer delivers to a specified load impedance under specified operating conditions. Usually expressed in decibels.

bridging transformer—Also called bridge transformer and hybrid coil. A transformer designed to couple two circuits having at least nominal ohmic isolation and operating at different impedance levels, without introducing significant frequency or phase distortion, or significant phase shift.

brightness—The attribute of visual perception in accordance with which an area appears to emit more or less light. Used with cathode-ray tubes.

brightness control—In a television receiver, the control which varies the average brightness of the reproduced image.

brightness signal—*See* Luminance Signal.

brilliance—1. The degree of brightness and clarity in a reproduced cathode-ray tube. 2. The degree to which the higher audio frequencies sound like the original when reproduced by a receiver or public-address amplifier.

brilliance control—A potentiometer used in a three-way speaker system to adjust the output level of the tweeter for proper relative volume between the treble and the lower audio frequencies produced by the complete speaker system.

broad band—As applied to data transmission, the term denotes transmission facilities capable of handling frequencies greater than those required for high-grade voice communications (higher than 3 to 4 kilohertz).

broad-band amplifier—An amplifier which has an essentially flat response over a wide frequency range.

broad-band antenna—An antenna which is capable of receiving a wide range of frequencies.

broad-band electrical noise—Also called random noise. A signal that contains a wide range of frequencies and has a randomly varying instantaneous amplitude.

broad-band interference—Interference occupying a frequency range that is much greater than the bandwidth of the equipment being used to measure it.

broad-band random vibration—Single-frequency component vibrations that are random in both phase and amplitude at minute increments of frequency throughout a specified bandwidth. Typically it occurs when intense, high-power-level noise impinges on structures.

broad-band tube (TR and pre-TR tubes)—A gas-filled, fixed-tuned tube incorporating a bandpass filter suitable for radio-frequency switching.

broadcast—Radio or television transmission intended for public reception, for which receiving stations make no receipt.

broadcast band—The band of frequencies extending from 535 to 1605 kHz.

broadcasting—The transmitting of speech, music, or visual programs for commercial or public-service motives to a relatively large audience (as opposed to two-way radio, for example, which is utilitarian and is directed toward a limited audience).

broadcasting service—A radiocommunication service in which the transmissions are intended for direct reception by the general public. This service may include sound transmissions, television transmissions, or other types of transmissions.

broadcasting station—A station in the broadcasting service.

broadside—A direction perpendicular to an axis or plane.

broadside array—An antenna array whose direction of maximum radiation is perpendicular to the line or plane of the array (depending on whether the elements lie on a line or a plane). A uniform broadside array is a linear array whose elements contribute fields of equal amplitude and phase.

broad tuning—A tuned circuit or circuits which respond to frequencies within one band or channel, as well as to a considerable range of frequencies on each side.

brush—A piece of conductive material, usually carbon or graphite, which rides on the commutator of a motor and forms the electrical connection between it and the power source.

brush discharge—An intermittent discharge of electricity which starts from a conductor when its potential exceeds a certain value but is too low for the formation of an actual spark. It is generally accompanied by a whistling or crackling noise.

brush-discharge resistance—*See* Corona Resistance.

brush rocker—A movable rocker, or "yoke," on which the brush holders of a dynamo or motor are fixed so that the position of the brushes on the commutator can be adjusted.

brush station—In a computer, a position where the holes of a punched card are sensed, particularly when this is done by a row of brushes sweeping electrical contacts.

brute-force filter—A type of power-pack filter which depends on large values of capacitance and inductance to smooth out pulsations, rather than on the resonant effects of a tuned filter.

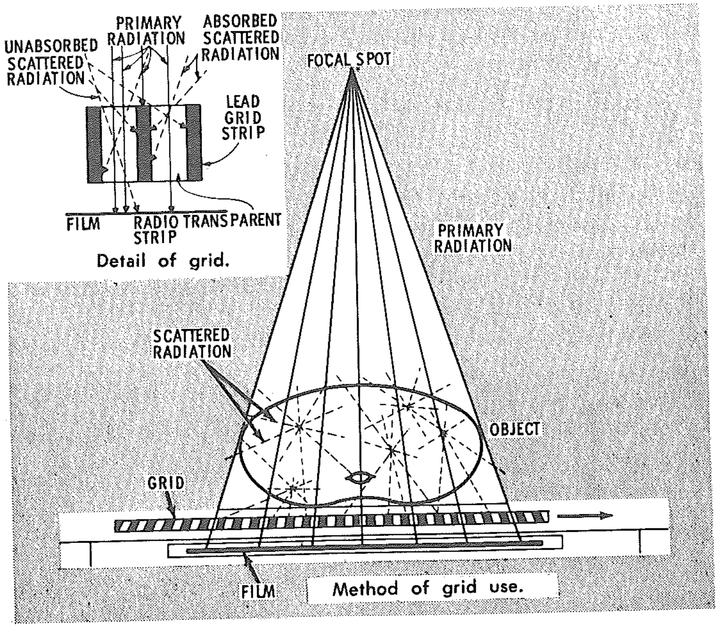
brute supply—One that is completely unregulated. It employs no circuitry to maintain the output voltage constant with a changing input line or load variations. The output voltage varies in the same percentage and in the same direction as the input line voltage. If the load current changes, the output voltage changes inversely—an increase in load current drops the output voltage.

B & S—Abbreviation for Brown and Sharpe gage. A wire-diameter standard that is the same as AWG.

B scope—A type of radarscope that presents the range of an object by a vertical deflection of the signal on the screen, and the bearing by a horizontal deflection.

"B" service—FAA service pertaining to transmission and reception by teletype or radio of messages containing requests for and approval to conduct an aircraft flight, flight plans, in-flight progress reports, and aircraft arrival reports.

B supply or B+ supply—A source for supplying a positive voltage to the anodes and other positive electrodes of electron tubes.



Bucky diaphragm.

buck—To oppose, as one voltage bucking another, or the magnetic fields of two coils bucking each other.

bucket—A general term for a specific reference in storage in a computer, such as a section of storage, the location of a word, a storage cell, etc.

bucking coil—A coil connected and positioned in such a way that its magnetic field opposes the magnetic field of another coil. The hum-bucking coil of an electrodynamic speaker is an example.

bucking voltage—A voltage which is opposite in polarity to another voltage in the circuit and hence bucks, or opposes, the latter voltage.

buckling—The warping of the plates of a battery due to an excessively high rate of charge or discharge.

Bucky diaphragm—A grid composed of narrow strips of lead arranged with X-ray–transparent spaces between adjacent strips and placed between the specimen and the X-ray film. Used to reduce scattered radiation.

buffer—1. A circuit or component which isolates one electrical circuit from another. Usually refers to electron-tube amplifiers used for this purpose. 2. A vacuum-tube stage used chiefly to prevent undesirable interaction between two other stages. In a transmitter, it generally follows the master-oscillator stage. 3. An isolating circuit used in an electronic computer to avoid reaction of a driven circuit on the corresponding driver circuit. 4. A storage device used to compensate for a difference in the rate of flow of information or the time or occurrence of events when transmitting information from one device to another. 5. A computer circuit having an output and a multiplicity of inputs and designed so that the output is energized whenever one or more inputs are energized. Thus, a buffer performs the circuit function equivalent to the logical OR.

buffer amplifier—An amplifier designed to isolate a preceding circuit from the effects of a following circuit.

buffer capacitor—A capacitor connected across the secondary of a vibrator transformer, or between the anode and cathode of a cold-cathode rectifier tube, to suppress voltage surges that might otherwise damage other parts in the circuit.

buffer element—A low-impedance inverting driver circuit. Because of its very low source impedance the element can supply substantially more output current than the basic circuit. As a consequence, the buffer element is valuable in driving heavily loaded circuits or minimizing rise-time deterioration due to capacitive loading.

buffer storage—In a computer, a synchronized element of storage between two other forms of storage. Computation may continue while data are being transferred between the buffer and the other storage.

bug—1. A semiautomatic telegraph sending key consisting of a lever which is moved to one side to produce a series of correctly spaced dots, and to the other side to produce a dash. 2. A circuit fault due to improper design or construction. 3. An electronic listening device, generally small and concealed, used for commercial or military espionage.

build—The increase of diameter due to insulation.

building-out—Addition to an electric structure of an element or elements electrically similar to an element or elements of the structure, to bring a certain property or characteristic to a desired value.

building-out circuit—A short section of transmission line, or a network which is shunted across a transmission line, for the purpose of impedance matching.

building-out network—A network designed to be connected to a basic network so that the combination will simulate the sending-end impedance, neglecting dissipation, of a line having a termination other than that for which the basic network was designed.

building-out section—A short section of transmission line, either open or short-circuited at the far end, shunted across another transmission line for use on an impedance-matching transformer.

bulb—The glass envelope which encloses an incandescent lamp or an electronic tube.

bulb-temperature pickup—A temperature transducer in which the sensing element is enclosed in a metal tube or sheath to protect it against corrosive liquids or other contaminants.

bulge—The difference between the actual characteristic and a linear characteristic of the attenuation-frequency characteristic of a transmission line.

bulk degausser—*See* Bulk Eraser.

bulk-erased noise—The noise arising when a bulk-erased tape is reproduced with the erase and record heads completely de-energized. Ideally, this noise is governed by the number of magnetic particles that pass by the head in unit time.

bulk eraser—Also called bulk degausser or degausser. Equipment for erasing a roll of tape. The roll is usually rotated while a 60-hertz a-c erasing field is decreased, either by withdrawing the roll from an electromagnet or by reducing the a-c supply to an electromagnet.

bulk noise—*See* Excess Noise.

bulk resistor—A resistor made by providing ohmic contacts between two points of a homogeneous, uniformly doped crystal of silicon material.

bump contracts—A small mound of material formed on the chip substrate, to register with terminal pads, as then the chip is employed in "flip-chip circuits."

bunched pair—A group of pairs tied together or otherwise associated for identification.

buncher—1. The input resonant cavity in a conventional klystron oscillator. 2. In a velocity-modulated tube, the electrode which concentrates the electrons in the constant-current electron beam into bunches.

buncher gap—*See* Input Gap.

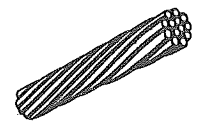
buncher resonator—The input cavity resonator in a velocity-modulated tube. It serves to modify the velocity of the electrons in the beam.

bunching—1. Grouping pairs together for identification and testing. 2. In a velocity-modulated electron stream the action that produces an alternating convection-current component as a direct result of the differences of electron transit time produced by the velocity modulation.

bunching parameter—One-half of the product of the bunching angle in the absence of velocity modulation and the depth of velocity modulation.

bunching time—The time in the armature motion of a relay during which all three contacts of a bridging-contact combination are electrically connected.

bunching voltage—The radio-frequency voltage between the grids of the buncher resonator in a velocity-modulated tube such as a klystron. Generally, the term implies the peak value of this oscillating voltage.



Bunch stranding.

bunch stranding—A method in which a number of wires are twisted together in a common direction and with a uniform pitch to form a finished, stranded wire.

bundled cable—Individual insulated wires laced together to form a bundle to facilitate handling.

buried cable—A cable installed underground and not removable except by disturbing the soil.

buried layer—A low-resistivity material introduced into a silicon substrate.

burned-in image—An image which remains in a fixed position in the output signal of a camera tube after the camera has been turned to a different scene.

burn-in—Operation of a device to stabilize its failure rate.

burn-in period—*See* Early Failure Period.

burst—1. A sudden increase in the strength of a signal. 2. The cosmic-ray effect upon matter, causing a sudden intense ionization that gives rise to great numbers of ion pairs at once. (*Also see* Color Burst.)

burst pedestal—A rectangular pulselike television signal which may be part of the color burst. The amplitude of the color-burst pedestal is measured from the alternating-current axis of the sine-wave portion of the horizontal pedestal.

burst pressure—The maximum pressure to which a device can be subjected without rupturing.

bus—1. In a computer, one or more conductors used as a path over which information is transmitted from any of several sources to any of several destinations. 2. The term used to specify an uninsulated conductor (a bar or wire); may be solid, hollow, square, or round. 3. Sometimes used to specify a bus bar. 4. The communications path between two switching points.

bus bar—A heavy copper strap or bar used to carry heavy currents or to make a common connection between several circuits.

bus reactor—A current-limiting reactor connected between two different buses or two sections of the same bus for the purpose of limiting and localizing the disturbance due to a fault on either bus.

bussback—The connection, by a common carrier, of the output portion of a circuit back to the input portion of a circuit. (*Also see* Loopback Test.)

busy test—In telephony, a test to find out whether certain facilities which may be desired, such as a subscriber line or a trunk, are available for use.

Butler oscillator—A two-tube (or transistor) crystal-controlled oscillator in which the crystal forms the positive feedback path when excited in its series-resonant mode.

butterfly resonator—Also called butterfly capacitor. A tuning device that combines both inductance and capacitance in such a manner that it exhibits resonant properties at very high and ultrahigh frequencies (characterized by a high tuning ratio and Q). So called because the shape of the rotor resembles the opened wings of a butterfly.

Butterworth filter—A filter network that exhibits the flattest possible response in the passband. The response is monotonic, rolling off smoothly into the stop band, where it approaches a constant slope of 6 db/octave.

butt joint—1. A splice or other connection formed by placing the ends of two conductors together and joining them by welding, brazing, or soldering. 2. A connection between two waveguides which maintains electrical continuity by providing physical contact between the ends.

button—1. The metal container in which the carbon granules of a carbon microphone are held. 2. Also called dot. A piece of metal used for alloying onto the base wafer in making alloy transistors.

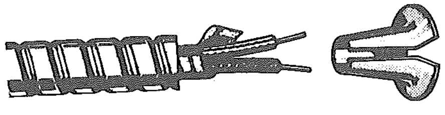
button silver-mica capacitor—A stack of silvered mica sheets encased in a silver-plated brass housing. The high-potential terminal is connected through the center of the stack. The other capacitor terminal is formed by the metal shell, which connects at all points around the outer edge of the electrodes. This design permits the current to fan out in a 360° pattern from the center terminal, providing the shortest possible electrical path between the center terminal and chassis. The internal series inductance is thus kept small.

button stem—In a tube, the glass base onto which the mount structure is assembled. The pins may be sealed into the glass; if so, no base is needed. In some large tubes, the stiff wires are passed directly into the base pins to give added strength. (*Also see* Pressed Stem.)

button up—To close or completely seal any operating device.

buzzer—A signaling device in which an armature vibrates to produce a raucous, nonresonant sound.

BV_{EBO}—The reverse-breakdown voltage of the emitter-to-base junction of a transistor with the collector open-circuited.



BX cable.

BX cable—Insulated wires in flexible metal tubing, used for wiring buildings and electrical and electronic equipment.

bypass—A shunt (parallel) path around one or more elements of a circuit.

bypass capacitor—A capacitor used for providing a comparatively low-impedance a-c path around a circuit element.

bypass filter—A filter providing a low-attenuation path around some other circuit or equipment.

B–Y signal—One of the three color-difference signals in color television. The B–Y signal forms a blue primary signal for the picture tube when combined—either inside or outside the picture tube—with a luminance or Y signal.

byte—A single group of bits processed together (in parallel). It can consist of a variable number of bits.

C

C—Symbol for capacitor, capacitance, carbon, coulomb, centigrade or Celsius, transistor collector, candle, velocity of light.

C– (C minus)—The negative terminal of a C battery, or the negative polarity of other sources of grid-bias voltage. Used to denote the terminal to which the negative side of the grid-bias voltage source should be connected.

C+ (C plus)—Positive terminal of a C battery, or the positive polarity of other sources of grid-bias voltage. The terminal to which the positive side of the grid-bias voltage source should be connected.

cabinet—A protective housing for electrical or electronic equipment.

cable—1. An assembly of one or more conductors, usually within a protective sheath, and so arranged that the conductors can be used separately or in groups. 2. A stranded conductor (single-conductor cable) or a combination of conductors insulated from one another (multiple-conductor cable).

cable assembly—A cable with plugs or connectors on each end for a specific purpose. It may be formed in various configurations.

cable clamp—A device used to give mechanical support to the wire bundle or cable at the rear of a plug or receptacle.

cable core—That portion of an insulated cable lying under the protective covering or jacket.

cable coupler—A device used to join lengths of similar or dissimilar cable having the same electrical characteristics.

cable fill—The ratio of the number in use to the total number of pairs in a cable.

cable filler—Material used in multiple-conductor cables to occupy the spaces between the insulated conductors.

cable Morse code—A three-element code used mainly in submarine-cable telegraphy. Dots and dashes are represented by positive and negative current impulses of equal length, and a space by the absence of current.

cable run—The path occupied by a cable on cable racks or other support from one termination to another.

cable sheath—A protective covering of rubber, neoprene, resin, or lead over a wire or cable core.

cable splice—A connection between two or more separate lengths of cable. The conductors in one length are individually connected to conductors in the other length, and the protecting sheaths are so connected that protection is extended over the joint.

cable terminal—A means of electrically connecting a predetermined number of cable conductors in such a way that they can be individually selected and extended by conductors outside the cable.

cable vault—A vault in which the outside plant cables are spliced to the tipping cables.

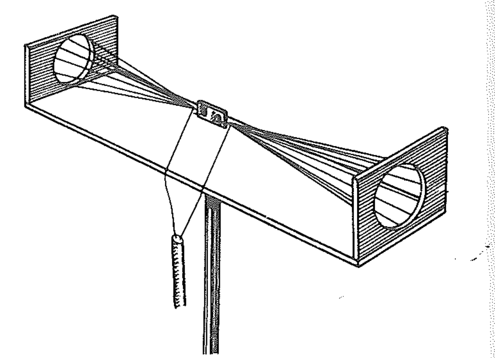
cabling—The method by which a group of insulated conductors is mechanically assembled (or twisted together).

cactus needle—A phonograph needle made from the thorn of a cactus plant.

cadmium—A metallic element widely used for plating steel hardware or chassis to improve its appearance and solderability and to prevent corrosion. It is also used in the manufacture of photocells.

cadmium selenide photoconductive cell—A photoconductive cell that uses cadmium selenide as the semiconductor material. It has a fast response time and high sensitivity to longer light wavelengths, such as those emitted by incandescent lamps and some infrared light sources.

cadmium sulfide photoconductive cell—A photoconductive cell in which a small wafer of cadmium sulfide is used to provide an extremely high dark-light resistance ratio. Some of the cells can be used directly as a light-controlled switch operated directly from the 120-volt a-c power line.



Cage antenna.

cage antenna—An antenna comprising a number of wires connected in parallel and arranged in the form of a cage. This is done to reduce the copper losses and increase the effective capacity.

calculating—Computing a result by multiplication, division, addition, or subtraction, or by a combination of these operations. A data-processing function.

calculating punch—A punched-card machine that reads data from a group of cards and punches new data in the same or other cards.

calculator—1. A device capable of performing arithmetic. 2. A calculator as in 1 which requires frequent manual intervention. 3. Generally and historically, a device for carrying out logical and arithmetical digital operations of any kind.

calendar age—Age of an item or object measured in terms of time elapsed since it was manufactured.

calendar life—That period of time expressed in days, months, or years during which an item may remain installed and in operation, but at the end of which the item should be removed and returned for repair, overhaul, or other maintenance.

calibrate—To ascertain, by measurement or by comparison with a standard, any variations in the readings of another instrument, or to correct the readings.

calibrated interference measurements—Measurements in which the meter is calibrated against a known sine wave or impulse-generator output and interference readings are taken directly from the output indicating meter on the receiver.

calibrated triggered sweep—In a cathode-ray oscilloscope, a sweep that occurs only when initiated by a pulse and moves horizontally at a known rate.

calibration—1. The process of comparing an instrument or device with a standard to determine its accuracy or to devise a corrected scale. 2. Taking measurements of various parts of electronic equipment to determine the performance level of the equipment and whether it conforms to technical order specifications.

calibration accuracy—Finite degree to which a device can be calibrated (influenced by sensitivity, resolution, and reproducibility of the device itself and the calibrating equipment). Expressed as a per cent of full scale.

calibration curve—A smooth curve connecting a series of calibration points.

calibration marker—On the screen of a radar indicator, the markings that divide the range scale into accurate intervals for range determination or checking against mechanical indicating dials, scales, or counters.

call—1. A transmission made for the purpose of identifying the transmitting station and the station for which the transmission is intended. 2. To transfer control to a specified closed subroutine. 3. In communication the action performed by the calling party, or the operations necessary in making a call, or the effective use made of a connection between two stations.

call circuit—A communication circuit between switching points used by traffic forces for transmitting switching instructions.

call in—To transfer control of a digital computer temporarily from a main routine to a subroutine, which is inserted in the sequence of calculating operations to fulfill a subsidiary purpose.

call letters—A series of government-assigned letters, or letters and numbers, which identify a transmitting station.

call sign—Any combination of characters or pronounceable words which identifies a communication facility, a command, an authority, an activity, or a unit; used primarily for establishing and maintaining communications.

call word—A call number which is exactly the size of one machine word.

calomel electrode—An electrode consisting of mercury in contact with a solution of potassium chloride saturated with mercurouse chloride (calomel). (*Also see* Glass Electrode.)

calorimeter—An apparatus for measuring quantities of heat. Used to measure microwave power in terms of heat generated.

calorimeter system—A precision r-f wattmeter as well as an efficient dummy load able to absorb energy at any frequency band. It can absorb and measure any level of microwave energy, and functions by circulating a known amount of liquid through a suitably designed low vswr load. The load is located in a wave-guide or coaxial section that mates to the termination of the r-f energy source being measured or absorbed.

camera—*See* Television Camera.

camera cable—A cable or group of wires that carry the picture signal from the television camera to the control room.

camera chain—A television camera, associated control units, power supplies, monitor, and connecting cables necessary to deliver a picture for broadcasting.

camera signal—The video-output signal of a television camera.

camera tube—An electron-beam tube in which an electron current or charge-density image is formed from an optical image and scanned in a predetermined sequence to provide an electric signal.

can—A metal shield placed around a tube, coil, or transformer to prevent electromagnetic or electrostatic interaction.

canal ray—Also called positive ray. Streams of positive ions that flow from the anode to the cathode in an evacuated tube.

candle—The unit of luminous intensity. One candle is defined as the luminous intensity of 1/60th square centimeter of a black-body radiator operating at the solidification temperature of platinum.

candlepower—Luminous intensity expressed in terms of standard candles.

candoluminescence—A phenomenon that produces white light without need for very high temperatures.

cannibalization—A method of maintenance or modification in which the required parts are removed from one system or assembly for installation on a similar system or assembly.

capacitance—1. Abbreviated C. Also called capacity. In a capacitor or a system of conductors and dielectrics, that property which permits the storage of electrically separated charges when potential differences exist between the conductors. The capacitance of a capacitor is defined as the ratio between the electric charge that has been transferred from one electrode to the other and the resultant difference in potential between the electrodes. The value of this ratio is dependent on the magnitude of the transferred charge.

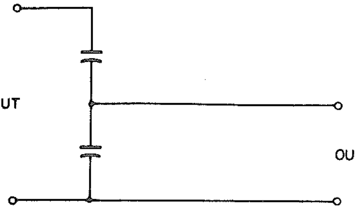
$$C\ (\text{farad}) = \frac{Q\ (\text{coulomb})}{V\ (\text{volt})}$$

2. In the case of fluid devices, it accumulates fluid by virtue of its volume and the pressure head available.

capacitance between two conductors—The ratio between the charge transferred from one conductor to the other and the resultant difference in the potentials of the two conductors when insulated from each other and from all other conductors.

capacitance divider—A circuit made up of capacitors and used for measuring the value of a high-voltage pulse by making available only a small, known fraction of the total pulse voltage for measurement.

capacitance meter—An instrument for measuring capacitance. If the scale is graduated in microfarads, the instrument is usually designated a microfaradmeter.



Capacitance divider.

capacitance-operated intrusion detector—A boundary alarm system in which the approach of an intruder to an antenna wire encircling the protected area (a few feet above ground) changes the antenna-ground capacitance and thereby sets off the alarm.

capacitance ratio—The ratio of maximum to minimum capacitance, as determined from a capacitance characteristic, over a specified voltage range.

capacitance relay—An electronic circuit incorporating a relay which responds to a small change in capacitance, such as that created by bringing the hand or body near a pickup wire or plate.

capacitive coupling—Also called electrostatic coupling. The association of two or more circuits with one another by means of mutual capacitance between them. Between stages of an amplifier, that type of interconnection which employs a capacitor in the circuit, between the plate of one tube and the grid of the succeeding tube.

capacitive divider—Two or more capacitors placed in series across a source, making available a portion of the source voltage across each capacitor. The voltage across each capacitor will be inversely proportional to its capacitance.

capacitive feedback—The process of returning part of the energy in the plate or output circuit of a vacuum tube to the grid, or input, circuit by means of a capacitance common to both circuits.

capacitive load—A predominantly capacitive load—i.e., one in which the current leads the voltage.

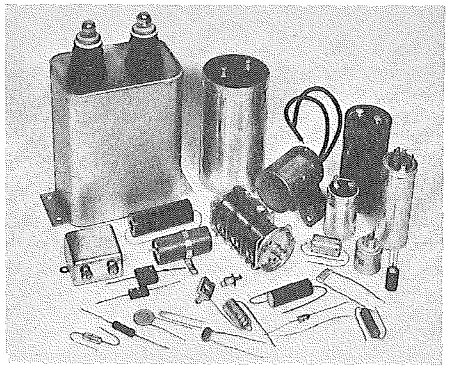
capacitive reactance—Symbolized by X_c. The impedance a capacitor offers to ac or pulsating dc. Measured in ohms and equal to $\frac{1}{2\pi fC}$, where f is in hertz and C is in farads.

capacitive speaker — *See* Electrostatic Speaker.

capacitive storage welding — A particular type of resistance welding whereby the energy is stored in banks of capacitors, which are then discharged through the primary of the welding transformer. The secondary current generates enough heat to produce the weld.

capacitive transduction—Conversion of the measurand into a change in capacitance.

capacitive tuning—Tuning by means of a variable capacitor.



Capacitors.

capacitivity—*See* Dielectric Constant.

capacitor—A device consisting essentially of two conducting surfaces separated by an insulating material or dielectric such as air, paper, mica, glass, plastic film, or oil. A capacitor stores electrical energy, blocks the flow of direct current, and permits the flow of alternating current to a degree dependent upon the capacitance and the frequency.

capacitor antenna—Also called condenser antenna. An antenna which consists of two conductors or systems of conductors and the essential characteristic of which is its capacitance.

capacitor bank—A number of capacitors connected together in series, parallel, or in series-parallel.

capacitor color code—Color dots or bands placed on capacitors to indicate one or more of the following: capacitance, capacitance tolerance, voltage rating, temperature coefficient, and the outside foil (on paper capacitors).

capacitor-input filter—A power-supply filter in which a capacitor is connected directly across, or in parallel with, the rectifier output.

capacitor microphone—*See* Electrostatic Microphone.

capacitor motor—A single-phase induction motor with the main winding arranged for direct connection to the power source, together with an auxiliary winding connected in series with a capacitor.

capacitor pickup — A phonograph pickup which depends for its operation on the variation of its electrical capacitance.

capacitor series resistance—An equivalent resistance in series with a pure capacitance which gives the same resultant losses as the actual capacitor. This equivalent circuit does not represent the variation in capacitor losses with frequency.

capacitor speaker—*See* Electrostatic Speaker.

capacitor-start motor—An a-c split-phase induction motor in which a capacitor is connected in series with an auxiliary winding to provide a means of starting. The auxiliary circuit opens when the motor reaches a predetermined speed.

capacitor voltage — The voltage across the terminals of a capacitor.

capacity—1. The current-output capability of a cell or battery over a period of time. Usually expressed in ampere-hours (amp-hr). 2. Capacitance. 3. The limits, both upper and lower, of the items or numbers which may be processed in a computer register, in the accumulator. When quantities exceed the capacity, a computer interrupt develops and requires special handling. 4. The total quantity of data that a part of a computer can hold or handle, usually expressed as words per unit of time. 5. The capability of a specific system to store data, accept transactions, process data, and generate reports.

capstan—The driven spindle or shaft in a tape recorder—sometimes the motor shaft itself—which rotates against the tape, pulling it through the machine at a constant speed during recording and playback modes of operation. The rotational speed and diameter of the capstan thus determine the tape speed.

capstan idler—*See* Pressure Roller.

captive screw—Screw-type fastener that is retained when unscrewed and cannot easily be separated from the part it secured.

capture effect — 1. The selection of the stronger of two frequency-modulated signals of the same frequency, with the complete rejection of the weaker signal. If both signals are of equal strength, both may be accepted and no intelligible signal will result. 2. An effect occurring in a transducer (usually a demodulator) whereby the input wave having the largest magnitude controls the output.

capture ratio—The ability of a tuner to reject unwanted f-m stations and interference on the same frequency as a desired one, measured in db. The lower the figure, the better the performance of the tuner.

carbon—One of the elements, consisting of a nonmetallic conductive material occurring as graphite, lampblack, diamond, etc. Its resistance is fifty to several hundred times that of copper and decreases as the temperature increases.

carbon brush — A current-carrying brush made of carbon, carbon and graphite, or carbon and copper.

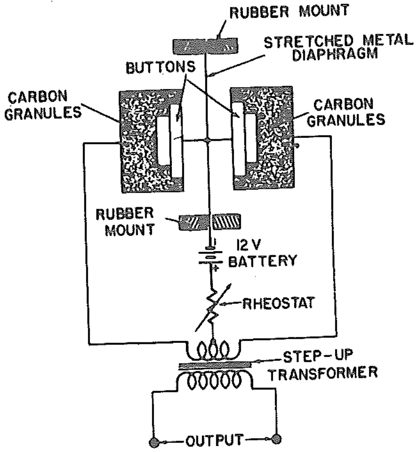
carbon-contact pickup—A phonograph pickup which depends for its operation on the variation in resistance of carbon contacts.

carbon-film resistor—A resistor formed by vacuum-depositing a thin carbon film on a ceramic form.

carbonize—To coat with carbon.

carbonized filament — A thoriated-tungsten filament treated with carbon. A layer of tungsten carbide formed on the surface slows down the evaporation of the active emitting thorium and thus permits higher operating temperatures and much greater electron emission.

carbonized plate—An electron-tube anode that has been blackened with carbon to increase its heat dissipation.



Carbon microphone.

carbon microphone—A microphone which depends for its operation on the variation in resistance of carbon contacts.

carbon-pile regulator—An arrangement of carbon discs the series resistance of which decreases as more pressure or compression is applied.

carbon resistor—Also called composition resistor. A resistor consisting of carbon particles which are mixed with a binder molded into a cylindrical shape, and then baked. Terminal leads are attached to opposite ends. The resistance of a carbon resistor decreases as the temperature increases.

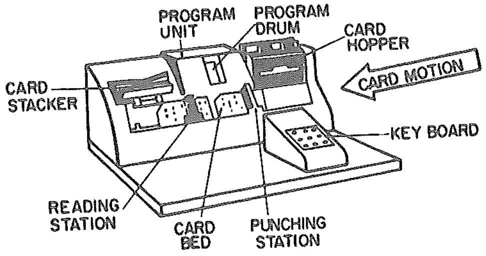
carbon transfer recording—A type of facsimile recording in which carbon particles are deposited on the record sheet in response to the received signal.

carborundum—A compound of carbon and silicon used in crystals to rectify or detect radio waves.

carcinotron—A voltage-tuned, backward-wave oscillator tube used to generate frequencies ranging from uhf up to 100GHz or more.

card—*See* Punched Card and Printed Circuit Board.

card bed — A mechanical device for holding punch cards to be transported past the punching and reading stations.

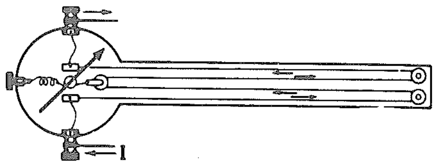


Card bed.

card code—An arbitrary code in which holes punched in a card are assigned numeric or alphabetic values.

card column—One of 20 to 90 single-digit columns in a tabulating card. When punched, a column contains only one digit, one letter, or one special code.

Cardew voltmeter—The earliest type of hot-wire instrument. It consisted of a small-diameter platinum-silver wire sufficiently long to give a resistance high enough to be connected directly across the circuit being measured. The wire was looped over pulleys and it expanded as current flowed, causing the pointer to rotate.



Cardew voltmeter.

card face—The printed side of a punched card if only one side is printed.

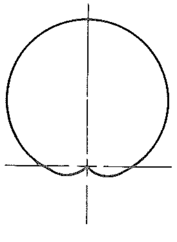
card feed—A mechanism that moves punch cards, one at a time, into a machine.

card field—On a punch card, the fixed columns in which the same type of information is routinely entered.

card hopper—*See* Card Stacker.

cardiac monitor—An instrument that usually has an oscilloscope display of the heart wave, and combines the features of several cardiac instruments such as an electrocardiograph, cardiotachometer, etc. May also allow upper and lower limits to be set and trigger audible and/or visual alarms when these limits are exceeded.

card image—1. A representation in storage of the holes punched in a card, in such a manner that the holes are represented by one binary digit and the unpunched spaces are represented by the other binary digit. 2. In machine language, a duplication of the data contained in a punch card.



Cardioid diagram.

cardiograph—An instrument (or recording of instruments) for measuring the form or force of heart motion.

cardioid diagram—Heart-shaped polar diagram showing the response or radiation characteristic of certain directional antennas, or the response characteristic of certain types of microphones.

cardioid microphone—A microphone that has a heart-shaped response pattern that gives nearly uniform response for a range of about 180° in one direction and a minimum response in the opposite direction.

cardiostimulator—A device used to stimulate the heart and/or regulate its beat. *Also see* Pacemaker and Defibrillator.

card jam—A pile-up of cards in a machine.

card machine—A machine used to transfer information from or to punched cards.

card programmed—1. The capability of being programmed by punched cards. 2. The capability of performing sequences of calculating operations according to instructions contained in a stack of punched cards.

card punch—A device to record information in cards by punching holes in the cards to represent letters, digits, and special characters.

card reader—A device designed to read punched cards and convert each hole into an electrical impulse for use in a computer system.

card row—On a punched card, one of the horizontal lines of punching positions.

card sensing—The process of sensing or reading the information in punched cards and converting this information, usually into electrical pulses.

card stacker—A mechanism that stacks cards in a pocket or bin after they have passed through a computer. Also called card hopper.

carillon—A bell tower designed to play from a keyboard. In an organ, this may be achieved by tube synthesis of bell-like tones struck with felt hammers, or completely electronically.

Carnot theorem—A thermodynamic principle which states that a cycle continuously operating between a low temperature and a high temperature can be no more efficient than a reversible cycle operating between the same temperatures.

carriage tape—*See* Control Tape.

carrier—1. A wave of constant amplitude, frequency, and phase which can be modulated by changing amplitude, frequency, or phase. 2. An entity capable of carrying an electric charge through a solid (e.g., holes and conduction electrons in semiconductors).

carrier-amplitude regulation—The change in amplitude of the carrier wave in an amplitude-modulated transmitter when symmetrical modulation is applied.

carrier beat—In facsimile transmission, an undesirable heterodyne of signals, each synchronous with a different stable oscillator, causing a pattern in received copy. Where one or more of the oscillators is fork-controlled, this is called fork beat.

carrier chrominance signal—In color television, sidebands of a modulated chrominance subcarrier, plus any unsuppressed subcarrier, added to the monochrome signal to convey color information.

carrier color signal—In color television, sidebands of a modulated chrominance subcarrier, plus the chrominance subcarrier, if not suppressed, which are added to the monochrome signal to convey color information.

carrier concentration—The number of carriers in a cubic centimeter of semiconductor material.

carrier control—A control by the presence or absence of an r-f carrier.

carrier current—The current associated with a carrier wave.

carrier-current communication—The superimposing of a high-frequency alternating current on ordinary telephone, telegraph, and power-line frequencies for telephone communication and control.

carrier-current control—Remote control in which the receiver and transmitter are coupled together through power lines.

carrier frequency—1. The frequency (hertz) of the wave modulated by the intelligence wave; usually a radio frequency (rf). 2. The reciprocal of the period of a periodic carrier.

carrier-frequency interconnection—In the formation of carrier networks, the transfer of groups of channels between terminals of wire-line cable or radio carrier systems at carrier frequencies.

carrier-frequency peak-pulse power—The power, averaged over that carrier-frequency cycle, which occurs at the maximum pulse of power (usually half the maximum instantaneous power).

carrier-frequency pulse—A carrier that is amplitude-modulated by a pulse. The amplitude of the modulated carrier is zero before and after the pulse.

carrier-frequency range—The continuous range of frequencies within which a transmitter may normally operate. A transmitter may have more than one carrier-frequency range.

carrier-frequency stereo disc—A stereo disc with two laterally-cut channels. One channel is cut in the usual manner. The second channel is employed to frequency-modulate a supersonic carrier frequency. The playback cartridge delivers the signal for one channel plus the carrier frequency containing the other channel. The latter must then be demodulated to obtain the second channel.

carrier-isolating choke coil—An inductor inserted in series with a line on which carrier energy is applied to impede the flow of carrier energy beyond that point.

carrier leak—The carrier-frequency signal remaining after suppression in a suppressed carrier system.

carrier level—The strength, expressed in decibels, of an unmodulated carrier signal at a particular point in a system.

carrier lifetime—The time required for excess carriers doped into a semiconductor to recombine with other carriers of the opposite sign.

carrier line—A transmission line used for multiple-channel carrier communications.

carrier loading—The insertion of additional lump inductance in a cable section of a transmission line utilized for carrier transmission up to about 35 kHz. Loading serves to minimize impedance mismatch between cable and open wire, and to reduce the cable attenuation.

carrier mobility—The average drift velocity of carriers per unit electric field in a homogeneous semiconductor. The mobility of electrons is usually different from that of holes.

carrier noise level—Also called residual modulation. The noise level produced by undesired variations of a radio-frequency signal in the absence of any intended modulation.

carrier power output rating—The power available at the output terminals of a transmitter when the output terminals are connected to the normal-load circuit or to a circuit equivalent thereto.

carrier repeater—An assembly, including an amplifier (or amplifiers), filters, equalizers, level controls, etc., used to raise the carrier signal level to a value suitable for traversing a succeeding line section while maintaining an adequate signal-to-noise ratio.

carrier shift—1. The transmission of radio teletypewriter messages by shifting the carrier frequency in one direction for a marking signal and in the opposite direction for a spacing signal. 2. The condition resulting from imperfect modulation, whereby the positive and negative excursions of the envelope pattern are unequal, thus effecting a change in the power associated with the carrier.

carrier signaling—In a telephone system, the method by which ringing, busy signals, or dial-signaling relays are operated by the transmission of a carrier-frequency tone.

carrier suppression—The method of operation in which the carrier wave is not transmitted.

carrier swing—The total deviation of a frequency- or phase-modulated wave from the lowest to the highest instantaneous frequency.

carrier system—A means of obtaining a number of channels over a single path by modulating each channel upon a different carrier frequency and demodulating at the receiving point to restore the signals to their original form.

carrier tap choke coil—A carrier-isolating choke coil inserted in series with a line tap.

carrier tap transmission choke coil—An inductor inserted in series with a line tap to control the amount of carrier energy flowing into the tap.

carrier telegraphy—That form of telegraphy in which the transmitted signal is formed by modulating the alternating current, under control of the transmitting apparatus, before supplying it to the line.

carrier telephony—Ordinarily applied only to wire telephony. That form of telephony in which carrier transmission is used, the modulating wave being at an audio frequency.

carrier terminal—Apparatus at one end of a carrier transmission system, whereby the processes of modulation, demodulation, filtering, amplification, and associated functions are effected.

carrier-to-noise ratio—Ratio of the magnitude of the carrier to the magnitude of the noise after selection and before any nonlinear process such as amplitude limiting and detection. This ratio is expressed in many different ways—for example, in terms of peak values in the case of impulse noise, and in terms of root-mean-square values in the case of random noise.

carrier-transfer filter—A group of filters arranged to form a carrier-frequency crossover or bridge between two transmission circuits.

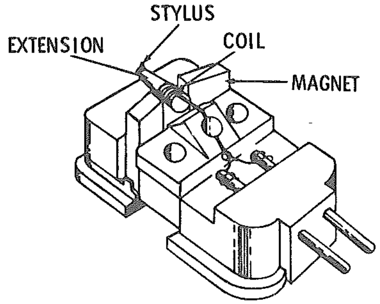
carrier transmission—That form of electrical transmission in which a single-frequency wave is modulated by another wave containing the information.

carrier type d-c amplifier—An amplifier system which converts a d-c input to modulated a-c amplifiers, and synchronously detects to provide amplified d-c output.

carrier wave—The single-frequency wave which is transmitted and which is modulated by another wave containing the information.

carry—1. A signal or expression produced in an electronic computer by an arithmetic operation on a one-digit place of two or more numbers expressed in positional notation and transferred to the next higher place for processing there. 2. A signal or expression—as defined in (1)—which arises when the sum of two digits in the same digit place equals or exceeds the base of the number system in use. If a carry into a digit place will result in a carry out of the same digit place and the normal adding circuit is bypassed when this new carry is generated, the result is called a high-speed or "stand-on-nines" carry. If the normal adding circuit is used, the result is called a cascade carry. If a carry resulting from the addition of carries is not allowed to propagate, the process is called a partial carry; if it is, a complete carry. A carry generated in the most significant digit place and sent directly to the least significant place is called an end-around carry. 3. In direct subtraction, a signal or expression—as defined in (1) above—which arises when the difference between the digits is less than zero. Such a carry is frequently called a borrow. 4. The action of forwarding a carry. 5. The command directing a carry to be forwarded.

carry time—The time required for a computer to transfer a carry digit to the next higher column and add it there.



Cartridge.

cartridge—A removable phonograph pickup.

cartridge fuse—A tubular fuse the end caps of which are enclosed in a glass or composition insulating tube to confine the arc or vapor when the fuse blows.

cascade—*See* Tandem.

cascade amplifier—A multiple-stage amplifier in which the output of each stage is connected to the input of the next stage.

cascade connection—Two or more similar component devices arranged in tandem, with the output of one connected to the input of the next.

cascade control—Also called piggy-back control. An automatic control system in which the control units, linked in chain fashion, feed into one another in succession. Each unit thus regulates the operation of the next in line.

cascaded carry—In a computer, a system of executing the carry process in which carry information cannot be passed on to place (N + 1) unless the Nth place has received carry information or produced a carry.

cascaded feedback canceler—Also called velocity-shaped canceler. A sophisticated moving-target indicator canceler which provides clutter and chaff rejection.

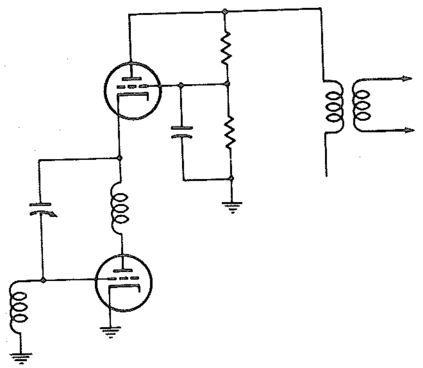
cascaded thermoelectric device—A thermoelectric device having two or more stages that are arranged thermally in series.

cascode amplifier—An amplifier using a neutralized grounded-cathode input stage followed by a grounded-grid output stage. The circuit has high gain, high input impedance, and low noise.

case pressure—The total differential pressure in the internal cavity of a transducer and the ambient pressure. The term is commonly used to summarize the limiting combined differential and/or line-pressure capabilities of differential transducers.

case temperature—The temperature on the surface of the case at a designated point.

Cassegrain antenna—An antenna the feed of which is positioned near the vertex of the reflector, with a small subreflector placed near the focal point. The feed illuminates the subreflector, and the subreflector redirects the waves toward the main reflector, which then forms the radiated beam (called the secondary beam or pattern). The shapes of the subreflector and main reflector are so chosen that the secondary rays will emerge parallel to the main-reflector axis.



Cascode amplifier.

casting-out-nines check—A partial verification of an arithmetical operation on two or more numbers. It involves casting out nines from the numbers and from the results.

catalyst—Also called hardener and promoter. A substance which markedly speeds up the cure of a casting or molding compound when added in a minor quantity as compared to the amounts of primary reactants.

catatastrophic failure—A sudden failure without warning, as opposed to degradation failure. Or, a failure the occurrence of which can prevent the satisfactory performance of an entire assembly or system.

catcher—In a velocity-modulated vacuum tube, an electrode on which the spaced electron groups induce a signal. The output of the tube is taken from this element.

catena—A chain or connected series.

catenate—*See* Concatenate.

catenation—*See* Concatenation.

cathamplifier—A push-pull amplifier in which the push-pull transformer is in the cathode circuit.

cathode—1. In an electron tube the electrode through which a primary source of electrons enters the interelectrode space. 2. General name for any negative electrode. 3. The lower-potential electrode of a corrosion cell where the action of the corrosion current may reduce or eliminate corrosion, or the negatively charged metallic parts of an impressed-current system. 4. When a semiconductor diode is biased in the forward direction, that terminal of the diode which is negative with respect to the other terminal.

cathode activity—Measure of the efficiency of an emitter. The mathematical relationship between two values of emission current measured under two conditions of cathode temperature.

cathode bias—A method of biasing a vacuum tube by placing the biasing resistor in the common cathode-return circuit, thereby making the cathode more positive—rather than the grid more negative—with respect to ground.

cathode-coupled amplifier—A cascade amplifier in which the coupling between two stages is accomplished by a common-cathode resistor.

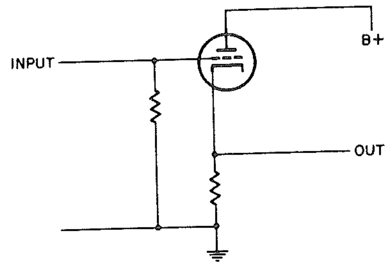
cathode coupling—The use of an input or output element in the cathode circuit for coupling energy to another stage.

cathode current—*See* Electrode Current.

cathode-current density—The current per square centimeter of cathode area, expressed as amperes or milliamperes per centimeter squared.

cathode dark space—Also called Crookes' dark space. The relatively nonluminous region between the cathode and negative glow in a glow-discharge—cold-cathode tube.

cathode emission—The process whereby electrons are emitted from the cathode structure.



Cathode follower.

cathode follower—Also called grounded-plate amplifier. A vacuum-tube circuit in which the input signal is applied to the control grid, and the output is taken from the cathode. Electrically, such a circuit possesses a high input impedance and a low output impedance characteristic and a gain of less than unity. The equivalent circuit using a transistor is called an emitter follower.

cathode glow—The luminous glow which covers the surface of the cathode in a glow-discharge—cold-cathode tube, between the cathode and the cathode dark space.

cathode guide—The element of a glow tube used in switching the neon glow from one indicated number to the next.

cathode heating time—The time required for the cathode to attain a specified condition—for example, a specified value of emission or a specified rate of change in emission.

cathode interface—A resistive and capacitive layer formed between the nickel sleeve and oxide coating of an indirectly-heated cathode. Raising the cathode temperature will largely nullify the layer.

cathode keying—A method of keying a radiotelegraph transmitter by opening the plate return lead to the cathode or filament center tap.

cathode luminous sensitivity (of a multiplier phototube)—The photocathode current divided by the incident luminous flux.

cathode modulation—A form of amplitude modulation in which the modulating voltage is applied to the cathode circuit.

cathode pulse modulation—Modulation produced in an amplifier or oscillator by applying externally generated pulses to the cathode circuit.

cathode radiant sensitivity—The current leaving the photocathode divided by the incident radiant power of a given wavelength.

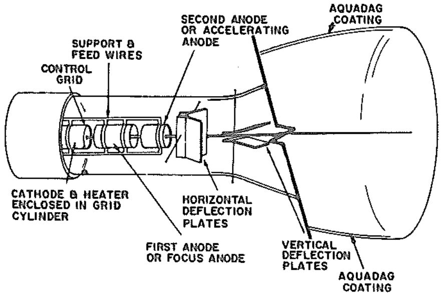
cathode ray—A stream of electrons emitted, under the influence of an electric field, from the cathode of an evacuated tube or from the ionized region nearby.

cathode-ray charge-storage tube — A charge-storage tube in which the desired information is written by means of a cathode-ray beam.

cathode-ray instrument—*See* Electron-Beam Instrument.

cathode-ray oscillograph — An apparatus capable of producing, from a cathode-ray tube, a permanent record of the value of an electrical quantity as a function of time.

cathode-ray oscilloscope—A test instrument which, when properly adjusted, makes possible the visual inspection of alternating-current signals. It consists of an amplifier, time-base generating circuits, and a cathode-ray tube for transformation of electrical energy into light energy.



SECOND ANODE OR ACCELERATING ANODE
AQUADAG COATING
SUPPORT & FEED WIRES
CONTROL GRID
CATHODE & HEATER ENCLOSED IN GRID CYLINDER
HORIZONTAL DEFLECTION PLATES
FIRST ANODE OR FOCUS ANODE
VERTICAL DEFLECTION PLATES
AQUADAG COATING

Cathode-ray tube.

cathode-ray tube—Abbreviated crt. A tube in which its electron beam can be focused to a small cross section on a luminescent screen and can be varied in position and intensity to produce a visible pattern.

cathode-ray tuning indicator — Commonly called magic eye. A small-diameter cathode-ray tube that visually indicates whether an apparatus such as a radio receiver is tuned precisely to a station.

cathode resistor—A resistance connected in the cathode circuit of a tube so that the voltage drop across it will supply the proper cathode-biasing voltage.

cathode spot—On the cathode of an arc, the area from which electrons are emitted at a current density of thousands of amperes per square centimeter and where the temperature of the electrode is too low to account for such currents by thermionic emission.

cathode sputtering—*See* Sputtering.

cathodic protection—The control of the electrolytic corrosion of an underground or underwater metallic structure by the application of an electric current through a sacrificial anode in such a way that the structure is made to act as a cathode of an electrolytic cell.

cathodolumninescence — Luminescence produced by the bombardment with high-velocity electrons of a metal in a vacuum. Small amounts of the metal are vaporized in an excited state by the bombardment and emit radiation characteristic of the metal.

cation—A positive ion that moves toward the cathode in a discharge tube, electrolytic cell, or similar equipment. The corresponding negative ion is called an "anion."

catv — Abbreviation for community antenna television.

catwhisker—A small, pointed wire used to make contact with a sensitive area on the surface of a crystal or semiconductor.

cavitation—In ultrasonic cleaning, the local formation of cavities in a liquid as the total pressure in that region is reduced.

cavitation noise — The noise produced in a liquid by the collapse of the bubbles created by cavitation.

cavity — A metallic enclosure inside which resonant fields may be excited at a microwave frequency.

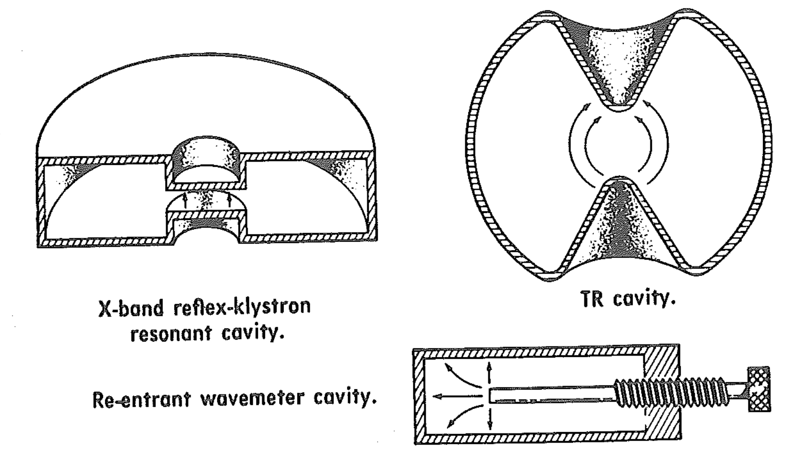
cavity filter—A selective tuned device having the proper coupling means for insertion into a transmission line to produce attenuation of unwanted off-frequency signals.

cavity impedance—The impedance that appears across the gap of the cavity of a microwave tube.

cavity magnetron—A magnetron having a number of resonant cavities forming the anode; used as a microwave-transmitting oscillator.

cavity radiation — The radiation (heat) emerging from a small hole leading to a constant-temperature enclosure. Such radiation is identical with black-body radiation at the same temperature, no matter what the nature of the inner surface of the enclosure.

cavity resonator—A space which is normally bounded by an electrically conducting surface and in which oscillating electromagnetic energy is stored; the resonant frequency is determined by the geometry of the enclosure.



X-band reflex-klystron resonant cavity.

TR cavity.

Re-entrant wavemeter cavity.

Cavities.

cavity-resonator frequency meter—A cavity resonator used for determining the frequency of an electromagnetic wave.

cavity-tuned, absorption-type frequency meter—A device used for measuring frequency. Its operation depends on the use of an enclosure with a conductive inner wall; the resonant frequency of the wall is determined by its internal dimensions.

cavity-tuned, heterodyne-type frequency meter—A device for measuring frequency. Its operation depends on the use of an enclosure, the resonant frequency of which is determined by its internal dimensions.

cavity-tuned, transmission-type frequency meter—A device for measuring frequency. Its operation depends on the use of an enclosure with a conductive inner wall; the resonant frequency of the wall is determined by its internal dimensions.

C-band—A radio-frequency band of 3.9 to 6.2 GHz, with wavelengths of 7.69 to 4.84 cm. It includes the top two sidebands of S-band, and the bottom three sidebands of the X-band.

C-battery—Also called grid battery. The energy source which supplies the voltage for biasing the grid of a vacuum tube.

C-bias—*See* Grid Bias.

CCIF — Abbreviation for International Telephone Consultative Committee.

CCIR—Abbreviation for International Radio Consultative Committee.

CCIT — Abbreviation for International Telegraph Consultative Committee.

CCS—Abbreviation for continuous commercial service. Refers to the power rating of transformers, tubes, resistors, etc. Used for rating components in broadcasting stations and some industrial applications.

ccw—Abbreviation for counterclockwise.

C-display—A type of radar display in which the signal is a bright spot, with the bearing as the horizontal and the elevation angle as the vertical co-ordinate.

celestial guidance—A system of guidance in which star sightings that are automatically taken during the flight of a missile provide position information used by the guidance equipment.

cell—1. A single unit that produces a direct voltage by converting chemical energy into electrical energy. 2. A single unit that produces a direct voltage by converting radiant energy into electrical energy—for example, a solar or photovoltaic cell. 3. A single unit that produces a varying voltage drop because its resistance varies with illumination. 4. Elementary unit of storage. 5. In corrosion processes, a source of electric potential that is responsible for corrosion. It consists of an anode and a cathode immersed in an electrolyte and electrically bonded together. The anode and cathode may be separate metals or dissimilar areas on the same metal. The different metals will develop a difference in potential that is accompanied by corrosion of the anode. When this cell involves an electrolyte as it does in corrosion processes, it is referred to as an electrolytic cell.

cell counter—An electronic instrument used to count white or red blood cells or other very small particles.

cell-type enclosure — A prefabricated basic shielded enclosure of double-walled copper-mesh construction. The original screen-room design.

cell-type tube (TR, ATR, and PRE-TR tubes)—A gas-filled, radio-frequency switching tube which operates in an external resonant circuit. A tuning mechanism may be incorporated into the external resonant circuit or the tube.

cellulose-nitrate discs — *See* Lacquer Disc.

Celsius temperature scale—Also called centigrade temperature scale. A temperature scale based on the freezing point of water defined as 0°C. and the boiling point defined as 100°C. both under conditions of normal atmospheric pressure (760 mm of mercury).

center frequency—1. Also called resting frequency. The average frequency of the emitted wave when modulated by a symmetrical signal. 2. The frequency at the center of a spectrum display (for linear frequency scanning). It is usually tunable.

centering control—One of two controls used to shift the position of the entire image on the screen of a cathode-ray tube. The horizontal-centering control moves the image to the right or left, and the vertical-centering control moves it up or down.

centering diode—A clamping circuit used in some types of plan-position indicators.

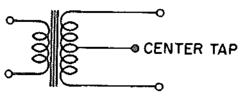
center of gravity—A point inside or outside a body and around which all parts of the body balance each other.

center of mass—On a line between two bodies, the point around which the two bodies would revolve freely as a system.

center poise—Scale of viscosity for insulating varnishes.

center ring—The part that supports the stator in an induction-motor housing. The motor end shields are attached to the ends of the center ring.

center tap—A connection at the electrical center of a winding, or midway between the electrical ends of a resistor or other portion of a circuit.



Center tap.

center-tapped winding—An internal tap at the center of a winding (three external leads).

center wire—A fine loop of wire used in proportional counters as an anode. A high voltage is applied to it to set the conditions for radiation measurement.

centigrade temperature scale—The older name for a Celsius temperature scale in the English-speaking countries. Officially abandoned by international agreement in 1948, but still in common usage.

centimeter waves—Microwave frequencies between 3 and 30 GHz, corresponding to wavelengths of 1 to 10 centimeters.

central processing unit—Also called central processor. Part of a computer system which contains the main storage, arithmetic unit, and special register groups. Performs arithmetic operations, controls instruction processing, and provides timing signals and other housekeeping operations.

Central Radio Propagation Laboratory—An organization, reporting to the Department of Commerce through the National Bureau of Standards, which is responsible for the collection, correlation, and analysis of data on which radio-propagation predictions are based, and issuance of radio-propagation predictions, and research on radio propagation and measurement methods and standards.

centrifugal force—The force which acts on a rotating body and which tends to throw the body farther from the axis of its rotation.

centripetal force—The force which compels a rotating body to move inward toward the center of rotation.

Ceracircuits—A trademark of the Sprague Electric Company for hybrid thick-thin film integrated circuits that consist of discrete passive and semiconductor active elements attached to precision resistor substrates to form functional electronic modules.

ceramic—A clay-like material, consisting primarily of magnesium and aluminum oxides, which after molding and firing is used as an insulating material. It withstands high temperatures and is less fragile than glass. When glazed, it is called porcelain.

ceramic-based microcircuit—A microminiature circuit printed on a ceramic substrate. Usually consists of combinations of resistive, capacitive, or conductive elements fired on a waferlike piece of ceramic.

ceramic capacitor—A capacitor the dielectric of which is a ceramic material such as steatite or barium titanate, the composition of which can be varied to give a wide range of temperature coefficients. The electrodes are usually silver coatings, fired on opposite sides of the ceramic disc or slab, or fired on the inside and outside of a ceramic tube. After connecting leads are soldered to the electrodes, the unit is usually given a protective insulating coating.

ceramic microphone—A microphone with a ceramic cartridge.

ceramic permanent magnet—A permanent, nonmetallic magnet made from pressed and sintered mixtures of metallic-oxide powders, usually oxides of barium and iron.

ceramic pickup—A phonograph pickup with a ceramic cartridge.

ceramic transducer—*See* Piezoelectric Transducer.

Cerenkov radiation—Light emitted when charged particles pass through a transparent material at a velocity greater than that of light in that material. It can be seen, for example, as a blue glow in the water around the fuel elements of pool reactors. P.A. Cerenkov was the Russian scientist who first explained the origin of this light.

Cerenkov rebatron radiator—A device in which a tightly bunched velocity-modulated electron beam is passed through a hole in a dielectric. The reaction between the higher velocity of the electrons passing through the hole and the slower velocity of the electromagnetic energy passing through the dielectric results in radiation at some frequency higher than the frequency of modulation of the electron beam.

cermet—A metal-dielectric mixture used in making thin-film resistive elements. The first half of the term is derived from *cer*amic and the second half from *met*al.

cesium—A chemical element having a low work function. Used as a getter in vacuum tubes and in cesium-oxygen-silver photocell cathodes.

cesium-vapor lamp—A low-voltage arc lamp for producing infrared radiation.

C_{gk}—Symbol for grid-cathode capacitance in a vacuum tube.

C_{gp}—Symbol for grid-plate capacitance in a vacuum tube.

cgs electromagnetic system of units—A coherent system of units for expressing the magnitude of electrical and magnetic quantities. The most common fundamental units of these quantities are the centimeter, gram, and second. Their unit of current (abampere) is of such a magnitude that if maintained constant in two straight parallel conductors having an infinite length and negligible circular sections and placed one centimeter apart in a vacuum, a force equal to 2 dynes per centimeter of length will be produced.

cgs electrostatic system of units—A coherent system of units for expressing the magnitude of electrical and magnetic quantities. The most common fundamental units of these quantities are the centimeter, gram, and second. Their unit of electrical charge (statcoulomb) is of such a magnitude that two equal unit point charges one centimeter apart in a vacuum will repel each other with a force of one dyne.

chad—The piece of material removed when a hole or notch is formed in a storage medium such as punched tape or punched cards.

chadless tape—A type of punched paper tape in which each chad is left fastened by about a quarter of the circumference of the hole. Chadless punched paper tape must be sensed by mechanical fingers, because chad interferes with reliable electrical or photoelectrical reading.

chafe—Undesirable rubbing with friction.

chaff—A general name applied to radar-confusion reflectors which consist of thin, narrow, metallic strips of various length and frequency responses used to reflect radar echoes.

chaining—In a computer, a system of storing records such that each record belongs to a list or group of records and has a linking field for tracing the chain.

chain printer—In a computer, a high-speed printer having type slugs carried on the links of a revolving chain.

chain radar system—A radar system comprising a number of radars or radar stations located at various sites along a missile-flight path. These radar stations are linked together by data and communication lines for target acquisition, target positioning, and/or data-recording purposes. The target-acquisition link makes it possible for any radar to position any other radar on target.

chain reaction—A reaction that stimulates its own repetition. In a fission chain reaction a fissionable nucleus absorbs a neutron and fissions, releasing additional neutrons. These in turn can be absorbed by other fissionable nuclei, releasing still more neutrons. A fission chain reaction is self-sustaining when the number of neutrons released in a given time equals or exceeds the number of neutrons lost by absorption in nonfissioning material or by escape from the system.

challenger—*See* Interrogator.

chance failure—*See* Random Failure.

channel—1. A portion of the spectrum assigned for the operation of a specific carrier and the minimum number of sidebands necessary to convey intelligence. 2. A single path for transmitting electric signals. (Note: The word "path" includes separation by frequency division or time division. Channel may signify either a one-way or two-way path, providing communication in either one direction only or in two directions.) *Also see* Alternate Channel. 3. In electric computers, that portion of a storage medium which is accessible to a given reading station. 4. The path along which information, particularly a series of digits or characters, may flow. 5. In computer circulating storage, one recirculating path containing a fixed number of words stored serially by word. 6. The main current path between the source and the drain in a field-effect transistor or other semiconductor.

channel balance—Equal response on both left and right channels.

channel capacity—The maximum possible information rate through a channel, subject to the constraints of that channel. May be either per second or per symbol.

channel frequency—The band of frequencies which must be handled by a carrier system to transmit a specific quantity of information.

channeling—The utilization of a modulation-frequency band for the simultaneous transmission from two or more communication channels in which the channel separation is accomplished by the use of carriers or subcarriers, each in a different discrete frequency band forming a subdivision of the main band. This covers a special case of multiplex transmission.

channel interval—The time allocated to a channel, including on and off time.

channelizing—The process of subdividing wideband transmission facilities for the purpose of putting many different circuits requiring comparatively narrow bandwidths on a single wideband facility.

channel pulse—Intelligence on a channel, by virtue of the modulation characteristic.

channel pulse synchronization—Synchronization of a local-channel rate oscillator by comparison and phase lock with separate channel synchronizing pulses.

channel reliability—The percentage of time that the channel meets the arbitrary standards established by the user.

channel reversal—Shifting the outputs of a stereo system so the channel formerly heard from the left speaker now comes from the right and vice versa.

channel-reversing switch—A switch that reverses the connections of two speakers in a stereo system with respect to the channels, so that the channel heard previously from the right speaker is heard from the left and vice versa.

channel sampling rate — The number of times per second that individual channels are sampled. This is different from commutation rate, since it is possible for more than one channel to be applied to a given commutator input (with subcommutation).

channel selector—A switch or dial used for selecting a desired channel.

channel separation—In stereo the electrical or acoustical difference between the left and right channels. Inadequate separation can lessen the stereo effect; excessive separation can exaggerate it beyond natural proportions.

channel strip—An amplifier, or other device having a sufficiently wide bandpass to amplify one television channel.

channel subcarrier—The channel required to convey telemetric data involving a subcarrier band.

channel synchronizing pulse separator—A device for separating channel synchronizing pulses from commutated signals.

channel-to-channel connection — A device for rapid data transfer between two computers. A channel adapter is available that permits the connection between any two channels on any two systems. Data are transferred at the rate of the slower channel.

channel-utilization index—In a computer, the ratio between the information rate (per second) through a channel and the channel capacity (per second).

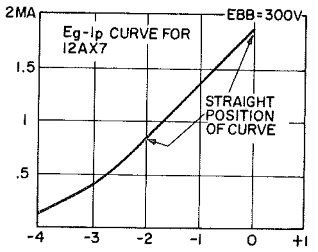
channel wave—Any elastic wave propagated in a sound channel because of a low-velocity layer in the solid earth, the sea, or the atmosphere.

character—1. In electronic computers, one of a set of elementary symbols which may be collectively arranged in order to express information. These symbols may include the decimal digits 0 through 9, the letters A through Z, punctuation and typewriter symbols, and any other single symbol which a computer may read, store, or write. 2. One of a set of symbols used to present information on a display tube.

character crowding—The effect of reducing the time interval between subsequent characters read from tape. It is caused by a combination of mechanical skew, gap scatter, jitter, amplitude variation, etc. Also called packing.

character emitter—In a computer, an electromechanical device that puts out coded pulses.

characteristic—An inherent and measurable property of a device. Such a property may be electrical, mechanical, thermal, hydraulic, electromagnetic, or nuclear; and it can be expressed as a value for stated or recognized conditions. A characteristic may also be a set of related values (usually in graphical form).



Characteristic curve.

characteristic curve—A graph plotted to show the relationship between changing values. An example would be a curve showing plate-current changes as the grid voltage varies.

characteristic distortion — Displacement of signal transitions due to the persistence of transients caused by preceding transitions.

characteristic frequency — The frequency which can be easily identified and measured in a given emission.

characteristic impedance—Also called surge impedance. 1. The driving-point impedance of a line if it were of infinite length. 2. In a delay line, the value of terminating resistance which provides minimum reflection to the network input and output. 3. The ratio of voltage to current at every point along a transmission line on which there are no standing waves. 4. The square root of the product of the open- and short-circuit impedance of the line.

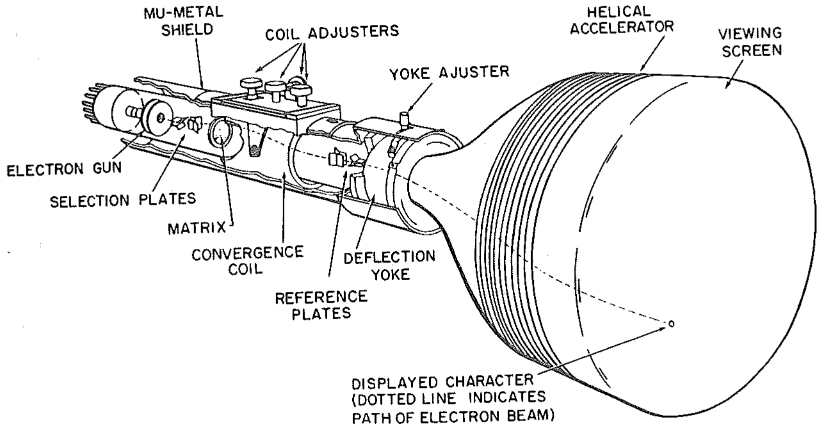
characteristic impedance of free space—The relationship between the electric and magnetic intensities of space due to the expansion of the impedance concept to electromagnetic fields.

characteristic spread—The range between the minimum and maximum values for a given characteristic that is considered normal in any large group of tubes or other devices.

characteristic telegraph distortion—Distortion which does not affect all signal pulses alike. Rather, the effect on each transition depends on the signal previously sent, because remnants of previous transitions or transients persist for one or more pulse lengths.

characteristic wave impedance—The ratio of the transverse electric vector to the transverse magnetic vector at the point it is crossed by an electromagnetic wave.

character reader — A computer input device which can directly recognize printed or written characters; they need not first be converted into punched holes in cards or paper or polarized magnetic spots.



Charactron.

character recognition — In a computer, the act of reading, identifying, and encoding a printed character.

character sensing — To detect the presence of characters optically, magnetically, electrostatically, etc.

Charactron—Trade name of General Dynamics/Electronics for a specially constructed cathode-ray tube used to display alphanumeric characters and other special symbols directly on its screen.

charge—1. The electrical energy stored in a capacitor or battery or held on an insulated object. 2. The quantity of electrical energy in (1) above.

charge carrier—A mobile hole or conduction electron in a semiconductor.

charge density—The charge per unit area on a surface, or charge per unit volume in space.

charged particle — An ion, an elementary particle that carries a positive or negative electric charge.

charger—A device used to convert alternating current into a pulsating direct current which can be used for charging a storage battery.

charge retention—The ability of a battery to hold its energy once it has been charged.

charge-storage tube—A storage tube which retains information on its surface in the form of electric charges.

charge transfer—The process in which an ion takes an electron from a neutral atom of the same type with a resultant transfer of electronic charge.

charging—The process of converting electrical energy to stored chemical energy.

charging current—The current that flows into a capacitor when a voltage is first applied.

charging rate—The rate of current flow used in charging a battery.

chassis—1. A sheet-metal box, frame, or simple plate on which electronic components and their associated circuitry can be mounted. 2. The entire equipment (less cabinet) when so assembled. (*Also see* Printed-Circuit Board.)

chassis ground—A connection to the metal structure that supports the electrical components which make up the unit or system.

chatter — 1. Prolonged undesirable opening and closing of electrical contacts. 2. The vibration of a cutting stylus in a direction other than the direction in which it is driven.

chatter time—The interval of time from initial actuation of a contact to the end of chatter.

check—The partial or complete verification of the correctness of equipment operations, the existence of certain prescribed conditions, and/or the correctness of results.

check digit—A digit carried along with a machine word and used to report information about the other digits in the word so that if a single error occurs, the check fails and an error alarm signal is initiated.

checkerboard—*See* Worst-Case Noise Pattern.

check point—In a computer routine, a point at which it is possible to store sufficient information to permit restarting the computation from that point.

check-point routine—A computer routine in which information for a check point is stored.

check problem—A problem which, when incorrectly solved, indicates an error in the programming or operation of a computer.

check register—A special register provided in some computers to temporarily store transferred information for comparison with a second transfer of the same information in order to verify that the information transferred each time agrees precisely.

check routine — A program the purpose of which is to determine whether a computer or a program is operating correctly.

checksum—In a computer, a summation of digits or bits summed according to an arbitrary set of rules and primarily used for checking purposes.

cheese antenna—An antenna with a cylindrical parabolic reflector enclosed by two plates perpendicular to the cylinder and so spaced that more than one mode can be propagated in the desired direction of polarization. It is fed on the focal line.

chelate—A molecule in which a central inorganic ion is covalently bonded to one or more organic molecules, with at least two bonds to each molecule; used as a laser dopant.

chemical deposition—The process of depositing a substance on a surface by means of the chemical reduction of a solution.

chemically deposited printed circuit—A printed circuit formed on a base by the reaction of chemicals alone. Dielectric, magnetic, and conductive circuits can be applied.

chemically reduced printed circuit—A printed circuit formed by chemically reducing a metallic compound.

chemisorption—*See* Adsorption.

Child's law—Also known as the three-halves power equation. It states that the current in a thermionic diode varies directly with the three-halves power of the anode voltage and inversely with the square of the distance between electrodes.

chip—1. Also called thread. In mechanical recording, the material removed from the recording medium by the recording stylus as it cuts the groove. 2. In punched cards, a piece of cardboard removed in the punching process. 3. A single substrate on which all the active and passive elements of an electronic circuit have been fabricated utilizing the semiconductor technologies of diffusion, passivation, masking, photoresist, and epitaxial growth. A chip is not ready for use until it is packaged and provided with terminals for connection to the outside world.

chirp—1. An all-encompassing term for the various techniques of pulse expansion-pulse compression applied to pulse radar. A technique to expand narrow pulses to wide pulses for transmission, and to compress wide received pulses to the original narrow pulse width and waveshape. This improves the signal-to-noise ratio without degradation to the range resolution and range discrimination. 2. A colloquial expression for a coded pulse. In coding the pulse, the carrier frequency is increased in a linear manner for the duration of the pulse, and when the pulse is translated to an audio frequency, it sounds like a chirp. 3. A change in the pitch of code signals, generally due to poor regulation of the transmitter power supply.

choke—An inductance used to impede the flow of pulsating direct current or alternating current by means of its self-inductance.

choke coil—Also called impedance coil. An inductor (reactor) used to limit or suppress the flow of alternating current without appreciable effect on the flow of direct current.

choke flange—A waveguide flange with a grooved surface; the groove is so dimensioned that the flange forms part of a choke joint.

choke-input filter—A power-supply filter in which a choke is the first element in series with the input.

choke joint—1. A connector between two sections of transmission line in which the gap between sections to be connected is built out to form a series-branching transmission line carrying a standing wave, in which actual contact falls at or near a current minimum. 2. A joint for connecting two sections of waveguide together. Permits efficient energy transfer without the necessity of an electrical contact at the inside surface of the guide.

chopped mode—A time-sharing method of displaying output signals of two or more channels with a single crt gun, in sequence, at a rate not referenced to the sweep.

chopper—1. A device for interrupting a current or a light beam at regular intervals. Choppers are frequently used to facilitate amplification. 2. An electromechanical switch for the production of modified square waves. The waves are of the same frequency as a driving sine wave and bear a definite relationship to it. 3. An electromechanical or electronic device used to interrupt a d-c or low-frequency a-c signal at regular intervals to permit amplification of the signal by an a-c amplifier. It may also be used as a demodulator to convert an a-c signal to dc. 4. A rotating shutter for interrupting an otherwise continuous stream of particles. Choppers can release short bursts of neutrons with known energies. Used to measure nuclear cross sections.

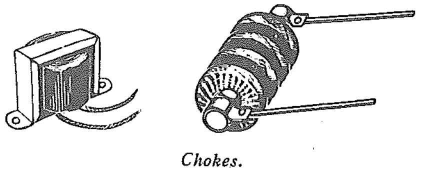
chopper amplifier—A circuit that amplifies a low-level signal after it has gone through a chopper.

chopper stabilization—1. The addition of a chopper amplifier to the regulator input circuitry of a regulated power supply in order to reduce output drift. 2. A method of improving the d-c drift of an amplifier by utilization of chopper circuits.

chopper-stabilized amplifier—An amplifier configuration utilizing a carrier-type d-c amplifier to reduce the effect of input offset and drift of a direct-coupled amplifier.

chopping—Removal by electronic means of one or both extremities of a wave at a predetermined level.

chord—A harmonious combination of tones sounded together through the use of one or more fingers on either or both hands. On chord organs a full chord is selected by depressing a single chord button.



Chokes.

chord organ—An organ with provision for playing a variety of chords, each produced by means of a single button or key.

chorus—A natural electromagnetic phenomenon in the vlf range. Probably originates in the exosphere. Also called "dawn chorus" because it sounds like birds at dawn. It generally consists of a multitude of rising tones, each tone rising from 1-2 kHz to 3-4 kHz and usually lasting 0.1 to 0.5 second.

Christmas-tree pattern—1. *See* Optical Pattern. 2. A pattern resembling a Christmas tree, sometimes produced on the screen of a television receiver when the horizontal oscillator falls out of sync.

chroma—That quality which characterizes a color without reference to its brightness; that quality which embraces hue and saturation. White, black, and gray have no chroma.

chroma-clear raster—Also called white raster. Looks like a clear raster, but each of the three guns in the crt is operating under the influence of a color level determined by a white video signal. In this case, all tv set chroma circuits are working as though the tv set were receiving a color transmission of a completely white scene.

chroma control—A variable resistor which controls saturation by varying the level of chrominance signal fed to the demodulators of a color television receiver.

chromatic aberration—An effect which causes refracted white light to produce an image with colored fringes due to the various colors being bent at different angles.

chromaticity—1. The combination of the hue and saturation attributes of color. 2. A term quantitatively descriptive of a color, and dependent upon both hue and saturation, but without reference to brilliance.

chromaticity coordinate—The ratio of any one of the tristimulus values of a sample color to the sum of the three tristimulus values.

chromaticity diagram—A plane diagram formed when any one of the three chromaticity co-ordinates is plotted against another.

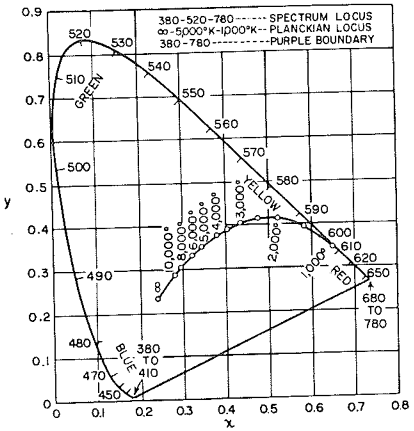
chromaticity flicker—The flicker which results from fluctuation of the chromaticity only.

chrominance—Colorimetric difference between any color and a reference color of equal luminance, the reference color having a specified chromaticity. In standard color-television transmission, the specified chromaticity is that of the zero subcarrier.

chrominance amplifier—The amplifier that separates the chrominance signal from the total video signal.

chrominance cancellation—A cancellation of the brightness variations produced by the chrominance signal on the screen of a monochrome picture tube.

chrominance-carrier reference—A continuous signal having the same frequency as the chrominance subcarrier, and a fixed phase with the color burst. The phase reference of carrier-chrominance signals for modulation or demodulation.



Chromaticity diagram.

chrominance channel—In color television, a combination of circuits designed to pass only those signals having to do with the reproduction of color.

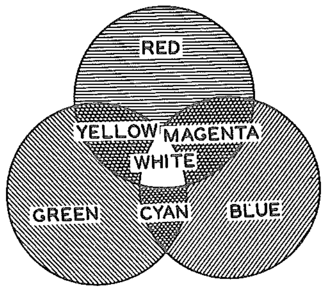
chrominance component—Either of the I and Q signals which add to produce the complete chrominance signal in NTSC systems.

chrominance demodulator—A demodulator used in color-television reception for deriving video-frequency chrominance components from the chrominance signal and a sine wave of the chrominance subcarrier frequency.

chrominance gain control—In red, green, and blue matrix channels, variable resistors which individually adjust the primary-signal levels. Used in color television.

chrominance modulator—A modulator used in color-television transmission for generating the chrominance signal from the video-frequency chrominance components and the chrominance subcarrier.

chrominance primary—One of two transmission primaries, the amounts of which deter-



Chrominance primaries.

mine the chrominance of a color. Chrominance primaries have zero luminance and are not physical.

chrominance signal—That portion of the composite color signal used to represent electrically the hues and saturation levels of the colors in a televised scene.

chrominance subcarrier — Also called color carrier. An r-f signal which has a specific frequency of 3.579545 MHz and which is used as a carrier for the I and Q signals.

chrominance-subcarrier oscillator — In a color-tv receiver, a crystal-controlled oscillator which generates the subcarrier signal for use in the chrominance demodulators.

chrominance video signals—Output voltages from the red, green, and blue sections of a color-television camera or receiver matrix.

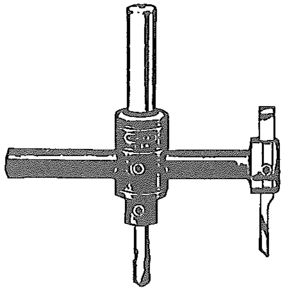
chronistor—A subminiature elapsed-time indicator that uses electroplating principles to totalize the operating time of equipment up to several thousand hours.

chronograph—An instrument for producing a graphical record of time as shown by a clock or other device.

chronometer — A portable timekeeper with compensated balance, capable of showing time with high precision and accuracy.

chronoscope—An instrument for measuring very small intervals of time.

CIE — Initials of the Commission Internationale de l'Eclairage or International Commission on Illumination.



Circle cutter.

circle cutter—A tool consisting of a center drill with an adjustable extension-arm cutter and used to cut holes in panels and chassis.

circle of confusion—The circular image of a point source due to the inherent aberrations in an optical system.

circlotron amplifier—A one-port, nonlinear cross-field high power microwave amplifier which uses a magnetron as a negative-resistance element, much as a maser uses an active material.

circuit—1. An electronic path between two or more points capable of providing a number of channels. 2. A number of conductors connected together for the purpose of carrying an electrical current. 3. The interconnection of a number of devices in one or more closed paths to perform a desired electrical or electronic function. Examples of simple circuits are high- or low-pass filters, multivibrators, oscillators, and amplifiers.

circuit analyzer — Also called multimeter. Several instruments or instrument circuits combined in a single enclosure and used in measuring two or more electrical quantities in a circuit.

circuit breaker—An automatic device which, under abnormal conditions, will open a current-carrying circuit without damaging itself (unlike a fuse, which must be replaced when it blows).

circuit-breaker cascade system—A system wherein the protective devices are arranged in order of ratings such that those in series will coordinate and provide the required protection.

circuit capacity—The number of communication channels which can be handled by a given circuit at the same time.

circuit dropout—A momentary interruption of a transmission because of the complete failure of a circuit.

circuit efficiency (of the output circuit of electron tubes)—Ratio of the power, at the desired frequency, delivered to a load at the output-circuit terminals of an oscillator or amplifier, to the power, at the desired frequency, delivered to the output circuit by the electron stream.

circuit element—Any basic constituent of a circuit except the interconnections.

circuit hole — On a printed-circuit board, a hole that lies partially or completely within the conductive area.

circuit noise—The noise brought to the receiver electrically from a telephone system, but not the noise picked up acoustically by the telephone transmitters.

circuit noise level—At any point in a transmission system, the ratio of the circuit noise at that point to some arbitrary amount of circuit noise chosen as a reference. This ratio is usually expressed in decibels above reference noise, abbreviated dbrn, signifying the reading of a circuit noise meter; or in adjusted decibels, abbreviated dba, signifying the circuit noise meter reading adjusted to represent interfering effect under specified conditions.

circuit-noise meter—Also called noise-measuring set. An instrument for measuring the circuit-noise level. Through the use of a suitable frequency-weighting network and other characteristics, the instrument gives equal readings for noises of approximately equal interference. The readings are expressed in decibels above the reference noise.

circuit parameters—The values of the physical quantities associated with circuit elements—for example, the resistance (parameter) of a resistor (element), the amplification factor and plate resistance (parameters) of a tube (element), the inductance per unit length (parameter) of a transmission line (element).

circuit protection—Automatic protection of a consequence-limiting nature used to minimize the danger of fire or smoke, as well as the disturbance to the rest of the system which may result from electrical faults or prolonged electrical overloads.

circuit re-entrancy—*See* Re-entrancy.

circuit reliability—The percentage of time the circuit meets arbitrary standards set by the user.

circuitry—A complex of circuits describing interconnection within or between systems.

circular antenna—A horizontally polarized antenna derived essentially from a half-wave antenna but having its elements bent into a circle.

circular electric wave—A wave with circular electric lines of force.

circular magnetic wave—A wave with circular magnetic lines of force.

circular mil—The universal term used to define cross-sectional areas. Equal to the area of a circle one mil (.001 inch) in diameter.

circular mil area—The square of the diameter of a round conductor measured in thousandths of an inch. The circular mil area of a braid is the sum of the circular mil area of each of the wires that make up the braid.

circular polarization—Polarization such that the vector representing the wave has a constant magnitude and rotates continuously about a point.

circular polarized wave—Applied usually to transverse waves. An electromagnetic wave for which the electric and/or magnetic field vector at a point describes a circle.

circular scan—A radar scan in which a given point on the direct beam describes a circle in space, with the antenna at the center.

circular scanning—Scanning in which the direction of maximum radiation generates a plane or a right circular cone with a vertex angle close to 180°.

circular trace—A cro time base produced by applying sine waves of the same frequency and amplitude, but 90° out of phase, to the horizontal- and vertical-deflection plates of a cathode-ray tube. This results in a circular trace, and signals then give inward or outward radial deflections from the circle.

circular waveguide—A waveguide having a circular cross-sectional area.

circulating memory — *See* Circulating Register.

circulating register—Also called circulating memory. A register (or memory) consisting of a means for delaying the information and a means for regenerating and reinserting it into the delaying means. This is accomplished as the information moves around a loop and returns to its starting place after a fixed delay.

circulating storage—A device using a delay line to store information in a train or pattern of pulses. The pulses at the output end are sensed, amplified, reshaped, and re-inserted into the input end of the delay line.

circulator — A microwave coupling device having a number of terminals so arranged that energy entering one terminal is transmitted to the next adjacent terminal in a particular direction.

Citizens band channels—

Channel No.	*Frequency (MHz)*	*Channel No.*	*Frequency (MHz)*
1	26.965	13	27.115
2	26.975	14	27.125
3	26.985	15	27.135
4	27.005	16	27.155
5	27.015	17	27.165
6	27.025	18	27.175
7	27.035	19	27.185
8	27.055	20	27.205
9	27.065	21	27.215
10	27.075	22	27.225
11	27.085	23*	27.255
12	27.105		

*This channel is shared with class-C radio control.

Citizens Radio Service—A type of radio service intended for private or personal use for communication, radio control, and similar purposes. A license can be obtained from the FCC; there is no need to take a technical examination. The frequencies assigned are in the 460-470-MHz and 26.965-27.255-MHz bands.

clamp—*See* Clamping Circuit.

clamper—*See* Clamping Circuit.

clamping — The process that establishes a fixed level for the picture signal at the beginning of each scanning line.

clamping circuit — Also called clamper or clamp. A circuit which adds a fixed bias to a wave at each occurrence of some predetermined feature of the wave. This is done to hold the voltage or current of the feature at (clamp it to) a specified fixed or variable level. (*Also see* D-C Restorer.)

clamping diode—A diode used to fix a voltage level at some point in a circuit.

clapotis—A standing wave in which there is no horizontal motion of the crest. This phenomenon results from the interference caused by the reflection of a wave train from a barrier which the wave train approaches with its crest parallel to the barrier.

clapper—A hinged or pivoted armature.

Clapp oscillator — A Colpitts-type oscillator using a series-resonant tank circuit for improved stability.

Clark cell—An early standard cell that used an anode of mercury, a cathode of zinc amalgam, and an electrolyte containing zinc sulphate and mercurous sulphate. Its voltage is 1.433 at 15°C.

class-A amplifier—An amplifier in which the grid bias and alternating grid voltage are such that plate current flows at all times. To denote that no grid current flows during any part of the input cycle, the suffix *1* is sometimes added to the letter or letters of the class identification. The suffix *2* denotes that grid current flows during part of the input cycle.

class-AB amplifier—An amplifier in which the grid bias and alternating grid voltage are such that plate current flows for more than half but less than the entire electrical cycle. To denote that no grid current flows during any part of the input cycle, the suffix *1* is sometimes added to the letter or letters of the class identification. The suffix *2* denotes that grid current flows during part of the cycle.

class-AO emission—The incidental radiation of an unmodulated carrier wave from a station.

class-A1 emission—A carrier wave (unmodulated by an audio frequency) keyed normally for telegraphy to transmit intelligence in the International Morse Code at a speed not exceeding 40 words per minute (the average word is composed of five letters).

class-A2 emission—A carrier wave which is amplitude-modulated at audio frequencies not exceeding 1,250 hertz. The modulated carrier wave is keyed normally for telegraphy to transmit intelligence in the International Morse Code at a speed not exceeding 40 words per minute, the average word being composed of five letters.

class-A3 emission—A carrier wave which is amplitude-modulated at audio frequencies corresponding to those necessary for intelligible speech transmitted at the speed of conversation.

class-A insulating material—A material or combination of materials such as cotton, silk, and paper suitably impregnated, coated, or immersed in a dielectric liquid such as oil. Other materials or combinations of materials may be included if shown to be capable of satisfactory operation at 105°C.

class-A modulator—A class-A amplifier used for supplying the signal power needed to modulate the carrier.

class-A operation—Operation of a vacuum tube with grid bias such that plate current flows throughout 360° of the input cycle.

class-A signal area—A strong tv signal area for vhf, 2,500 microvolts per meter or greater; and for uhf, 5,000 microvolts per meter or greater.

class-A transistor amplifier—An amplifier in which the input electrode and alternating input signal are biased so that output current flows at all times.

class-B amplifier—An amplifier in which the grid bias is approximately equal to the cutoff value so that, when no exciting grid voltage is applied, the plate current will be approximately zero and will flow for approximately half of each cycle when an alternating grid voltage is applied. To denote that no grid current flows during any part of the input cycle, the suffix *1* is sometimes added to the letter or letters of the class identification. The suffix *2* denotes that grid current flows during part of the cycle.

class-B insulating material — A material or combination of materials such as mica, glass fiber, asbestos, etc., suitaby bonded. Other materials or combinations, not necessarily inorganic may be included if shown to be capable of satisfactory operation at 130°C.

class-B modulator—A class-B amplifier used specifically for supplying the signal power needed to modulate a carrier.

class-B operation—Operation of a vacuum tube with the grid bias set at or very near cutoff, so that plate current flows for approximately the positive half of each cycle of the input signal.

class-B transistor amplifier—An amplifier in which the input electrode is biased so that when no alternating input signal is applied, the output current is approximately zero, and when an alternating input signal is applied, the output current flows for approximately half a cycle.

class-C amplifier—An amplifier in which the grid bias is appreciably beyond the cutoff point, so that plate current is zero when no alternating grid voltage is applied, and plate current flows for appreciably less than half of each cycle when an alternating grid voltage is applied. To denote that no grid current flows during any part of the input cycle, the suffix *1* is sometimes added to the letter or letters of the class identification. The suffix *2* denotes that grid current flows during part of the cycle.

class-C insulating material—Insulation consisting entirely of mica, porcelain, glass, quartz, or similar inorganic materials. Other materials or combinations of materials may be included if shown to be capable of satisfactory operation at temperatures over 220°C.

class-C operation—Operation of a vacuum tube with grid bias considerably greater than cutoff. The plate current is zero with no input signal to the grid and flows for appreciably less than one-half of each cycle of the input signal.

class-F insulating material—A material or combination of materials such as mica, glass fiber, asbestos, etc., suitably bonded. Other materials or combinations of materials, not necessarily inorganic, may be included if shown to be capable of satisfactory operation at 155°C.

class-H insulating material—A material or combination of materials such as silicone elastomer, mica, glass fiber, asbestos, etc., suitably bonded. Other materials or combinations of materials may be included if shown to be capable of satisfactory operation at 180°C.

class-J oscilloscope—*See* J-Scope.

class-O insulating material—An unimpregnated material or combination of materials such as cotton, silk, or paper. Other materials or combinations of materials may be included if shown to be capable of satisfactory operation at 90°C.

clavier — Any keyboard, either hand or foot operated.

clean room—An area in which high standards of control of humidity, temperature, dust and all forms of contamination are maintained.

clear—Also called reset. To restore a storage or memory device to a prescribed state, usually to zero.

clearance — The shortest distance through space between two live parts, between live parts and supports or other objects, or between any live part and grounded part.

clearing ends — The operation of removing the sheath from the end of a cable, eliminating all moisture, and checking for crosses, shorts, and grounds in preparation for testing.

clear raster—A raster free of snow such as would be obtained in the absence of a video signal on either the cathodes or the grids of the three guns in the color crt (mostly a function of bias conditions).

click filter—A capacitor and resistor connected across the contacts of a switch or relay to prevent a surge being introduced into an adjacent circuit. (*Also see* Key-Click Filter.)

clipped-noise modulation—A clipping action performed to increase the bandwidth of a jamming signal. Results in more energy in the sidebands, correspondingly less energy in the carrier, and an increase in the ratio of average power to peak power.

clipper—A device the output of which is zero or a fixed value for instantaneous input amplitudes up to a certain value, but is a function of the input for amplitudes exceeding the critical value.

clipper amplifier—An amplifier designed to limit the instantaneous value of its output to a predetermined maximum.

clipper-limiter—Also called slicer. A device the output of which is a function of the instantaneous input amplitude for a range of values lying between two predetermined limits, but is approximately constant at another level for input values above the range.

clipping—The loss of initial or final parts of words or syllables due to less-than-ideal operation of voice-operated devices.

clock—The primary source of synchronizing signals in electronic computers.

clocked flip-flops—Directly coupled units operating on the "master-slave" principle. Information enters the "master" while the trigger input voltage is high, and transfers to the "slave" when the trigger input voltage goes low.

clock frequency—In digital computers, the master frequency of periodic pulses that are used to schedule the operation of the computer.

clock rate—The rate at which a word or characters of a word (bits) are transferred from one internal computer element to another. Clock rate is expressed in cycles (in a parallel-operation machine, in words; in a serial-operation machine, in bits) per second.

clockwise-polarized wave — *See* Right-Handed Polarized Wave.

close coupling—Also called tight coupling. Any degree of coupling greater than critical coupling.

closed array—An array which cannot be extended at either end.

closed circuit—1. A complete electric circuit through which current may flow when a voltage is applied. 2. A program source that is not broadcast for general consumption, but is fed to remote monitoring units by wire.

closed-circuit communication systems — Certain communication systems which are entirely self-contained and do not exchange intelligence with other facilities and systems.

closed-circuit signaling—Signaling in which current flows in the idle conditions and a signal is initiated by increasing or decreasing the current.

closed-circuit television—A television system in which the television signals are not broadcast, but are transmitted over a closed circuit and received only by interconnected receivers.

closed entry—A design that places a limit on the size of a mating part.

closed loop—1. A circuit in which the output is continuously fed back to the input for constant comparison. 2. In a computer, a group of indefinitely repeated instructions.

closed-loop bandwidth — The frequency at which the closed-loop gain drops 3 db from its midband or d-c value.

closed-loop gain — The response of a feedback circuit to a voltage inserted in series with the amplifier input.

closed-loop input impedance—The impedance looking into the input port of an amplifier with feedback.

closed-loop output impedance—The impedance looking into the output port of an operational amplifier with feedback.

closed-loop voltage gain—The voltage gain of an amplifier with feedback.

closed magnetic circuit—A circuit in which the magnetic flux is conducted continuously around a closed path through ferromagnetic materials.

closed routine — In a computer, a routine that is entered by basic linkage from the main routine rather than being inserted as a block of instructions within a main routine.

close-talking microphone—Also called noise-cancelling microphone. A microphone designed to be held close to the mouth of the speaker.

closing rating—In a relay, conditions under which the contact must close, with a prescribed duty cycle and contact life.

cloverleaf antenna—An nondirectional vhf transmitting antenna that consists of a number of horizontal four-element radiators arranged much like a four-leaf clover, stacked a half-wave apart vertically. These horizontal units are energized to give maximum radiation in the horizontal plane.

clutter—Confusing, unwanted echoes which interfere with the observation of desired signals on a radar display.

clutter gating—The technique which provides switching between moving-target indicators and normal videos. This results in normal video being displayed in regions with no clutter, and moving-target indicator video being switched in only for the clutter areas.

CML—Abbreviation for current mode logic.

C-network—A network composed of three impedance branches in series. The free ends are connected to one pair of terminals, and the junction points to another pair.

coarse-chrominance primary—Also called the Q signal. A zero-luminance transmission primary associated with the minimum bandwidth of chrominance transmission and chosen for its relatively small importance in contributing to the subjective sharpness of the color picture.

coast—On a radar, a memory feature which, when activated, causes the range and/or angle systems to continue to move in the same direction and at the same speed as an original target was moving. Used to prevent lock-up to a stronger target if approached by the target being tracked.

coast station—A land-based radio station in the maritime mobile service. It carries on communications with shipboard stations.

coated cathode—In a vacuum tube, a cathode that has been coated with compounds so as to increase its electron emission (e.g., an oxide-coated cathode).

coated filament—A vacuum-tube filament that has been coated with metal oxides to increase its electron emission.

coating—The magnetic layer, consisting of oxide particles held in a binder that is applied to the base film, used for magnetic recordings.

coating thickness—The thickness of the magnetic coating applied to the base film. Modern tape coatings range in thickness from 170 to 650 microinches, with a preponderance of coatings being approximately 400 microinches thick. In general, thin coatings give good resolution, at the expense of reduced output at long wavelengths; thick coatings give a high output at long wavelengths, at the expense of degraded resolution.

coated tape—*See* Magnetic-Powder—Coated Tape.

coaxial antenna—An antenna comprised of a quarter-wavelength extension to the inner conductor of a coaxial line, and a radiating sleeve which in effect is formed by folding back the outer conductor of the coaxial line for approximately one-quarter wavelength.

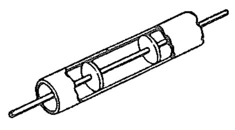
coaxial cable—*See* Coaxial Line.

coaxial cavity—A cylindical reasonating cavity that has a central conductor in contact with its movable pistons or other reflecting devices. The conductor serves to pick up a desired wave in the microwave region.

coaxial diode—A diode that has the same outer diameter and terminations as a coaxial cable into which the diode is designed to be inserted.

coaxial-fed linear array—A beacon antenna having a uniform azimuth pattern.

coaxial filters—A passive, linear, essentially nondissipative network that transmits certain frequencies and rejects others.



Coaxial line.

coaxial line—Also called coaxial cable, coaxial transmission line, and concentric line. A transmission line in which one conductor completely surrounds the other, the two being coaxial and separated by a continuous solid dielectric or by dielectric spacers. Such a line has no external field and is not susceptible to external fields from other sources.

coaxial-line connector—A connection between two coaxial lines, or between a coaxial line and the equipment.

coaxial-line frequency meter—A shorted section of coaxial line which acts as a resonant circuit and is calibrated in terms of frequency or wavelength.

coaxial relay—A type of relay used for switching high-frequency circuits.

coaxial speaker—A single speaker comprising a high and a low-frequency unit plus an electrical crossover network.

coaxial stub—A short length of coaxial cable joined as a branch to another coaxial cable. Frequently a coaxial stub is short-circuited at the outer end, and its length is so chosen that a high or low impedance is presented to the main coaxial cable at a certain frequency range.

coaxial transistor—A diffused-base, alloy-emitter, epitaxial mesa germanium semiconductor device with a bandwidth product up to 3 gigahertz capable of being operated at medium power.

coaxial transmission line—*See* Coaxial Line.

COBOL—Acronym for COmmon Business Oriented Language. Used to express problems of data manipulation and processing in English narrative form.

co-channel interference—Interference between two signals of the same type from transmitters operating on the same channel.

Cockcroft-Walton accelerator—A device for accelerating charged particles by the action of a high direct-current voltage on a stream of gas ions, in a straight insulated tube. The voltage is generated by a voltage-multiplier system consisting essentially of a number of condenser pairs connected through switching devices (vacuum tubes). The particles (which are nuclei of an ionized gas, such as protons from hydrogen) gain energies of up to several million electron-volts from the single acceleration so produced. Named for the British physicists J. D. Cockcroft and E.T.S. Walton, who developed this machine in the 1930's.

codan—Acronym for Carrier-Operated Device, Anti-Noise. An electronic circuit that keeps a receiver inactive except when a signal is received.

codan lamp—A visual indication that a usable transmitted signal has been received by a particular radio receiver.

code—1. A communications system in which arbitrary groups of symbols represent units of plain text of varying length. Codes may be used for brevity or security. 2. System of signaling by utilizing dot-dash-space, mark-space, or some other method where each letter or figure is represented by prearranged combinations. 3. System of characters and rules for representing information. 4. Loosely, the set of characters resulting from the use of a code.

code character—One of the elements which make up a code and which represent a specified symbol or value to be encoded. Dot-dot-dot-dash is the Morse code character for the letter V.

coded decimal digit—A decimal digit expressed in terms of four or more ones and zeros.

coded passive reflector antenna—An object intended to reflect Hertzian waves and having variable reflecting properties according to a predetermined code for the purpose of producing an indication on a radar receiver.

coded program—A description of a procedure for solving a problem with a digital computer. It may vary in detail from a mere outline of the procedure to an explicit list of instructions coded in the machine's language.

code element—One of the finite set of parts of which the characters in a code may be composed.

code-practice oscillator—An audio oscillator with a key and either headphones or a speaker, used to practice sending and receiving Morse code.

coder—1. A device which sets up a series of signals in code form. 2. A beacon circuit which forms the trigger-pulse output of a discriminator into a series of pulses and then feeds them to a modulator circuit. 3. A person who prepares instruction sequences from detailed flowcharts and other algorithmic procedures prepared by others, as contrasted with a programmer who prepares the procedures and flowcharts.

coding—1. Converting program flowcharts into the language used by the computer. 2. The assignment of identification codes to transactions, such as a customer code number. 3. A method of representing characters within a computer.

codiphase radar—A radar system including a phased-array radar antenna and signal-processing and beam-forming techniques.

codistor—A multijunction semiconductor device which provides noise-rejection and voltage-regulation functions.

coefficient—The ratio of change under specified conditions of temperature, length, volume, etc.

coefficient of coupling—*See* Coupling Coefficient.

coefficient of performance of a thermoelectric cooling couple—The quotient of the net rate of heat removal from the cold junction divided by the electrical power input to the thermoelectric couple, assuming perfect thermal insulation of the thermoelectric arms.

coefficient of performance of a thermoelectric cooling device—The quotient of the rate at which heat is removed from the cooled body divided by the electrical power input to the device.

coefficient of performance of a thermoelectric heating couple—The quotient of the rate at which heat is added to the hot junction divided by the electrical power input to the thermoelectric couple, assuming perfect thermal insulation of the thermoelectric arms.

coefficient of performance of a thermoelectric heating device—The quotient of the rate at which heat is added to the heated body divided by the electrical power input to the device.

coercive force—Symbolized by H. The magnetizing force that must be applied to a magnetic material in a direction opposite the residual induction in order to reduce the induction to zero.

coercivity—The property of a magnetic material measured by the coercive force corresponding to the saturation induction for the material.

cogging—Nonuniform angular velocity. The armature coil of a motor tends to speed up when it enters the magnetic field produced by the field coils, and to slow down when leaving it. This becomes apparent at low speeds, and the fewer the coils, the more noticeable it is.

coherent carrier—A carrier, derived from a c-w signal, the frequency and phase of which have a fixed relationship to the frequency and phase of the reference signal.

coherent detection—A method of deriving additional information from the phase of the carrier.

coherent electroluminescence device—*See* Diode Laser.

coherent interrupted waves—Interrupted continuous waves occurring in wave trains in which the phase of the waves is maintained through successive wave trains.

coherent light—A single frequency of light. Light having characteristics similar to a radiated radio wave that has a single frequency.

coherent light detection and ranging—*See* Colidar.

coherent oscillator—An oscillator within some radar sets which furnishes phase references for target returns during intervals between transmitter pulse, and its output compared with the returns so that the echo becomes coherent video. Coherent video is applied to a cancellation circuit which eliminates nonmoving targets, and only moving targets are supplied to the indicator.

coherent-pulse operation — The method of pulse operation in which a fixed phase relationship is maintained from one pulse to the next.

coherent radiation—A form of radiation in which definite phase relationships exist between radiation at different positions in a cross section of the radiant beam.

coherent reference—The reference signal, usually of stable frequency, to which other signals are phase-locked to establish coherency throughout a system.

coherent system of units—Also called absolute system of units. A system of units in which the magnitude and dimensions of each unit are related to those of the other units by definite simple relationships in which the proportionality factors are usually chosen to be unity.

coherent transponder—A transponder, the output signal of which is coherent with the input signal. Fixed relations between frequency and phase of input and output signals are maintained.

coherer—An early form of detector used in wireless telegraphy.

coil—A number of turns of wire wound around an iron core or onto a form made of insulating material, or one which is self-supporting. A coil offers considerable opposition to the passage of alternating current, but very little opposition to direct current.

coil dissipation—The amount of electrical power consumed by a winding. For the most practical purposes, this equals the I^2R loss.

coil form—An insulating support of ceramic, plastic, or cardboard onto which coils are wound.

coil loading—As commonly understood, the insertion of coils into a line at uniformly spaced intervals. However, the coils are sometimes inserted in parallel.

coil neutralization — *See* Inductive Neutralization.

coil rating—*See* Input-Power Rating.

coil resistance—The total terminal-to-terminal resistance of a coil at a specified temperature.

coil serving—A covering, such as thread or tape, that serves to protect a coil winding from mechanical damage.

coil temperature rise — The increase in winding temperature above the ambient temperature when energized under specified conditions for a given period of time, usually that required to reach a stable temperature.

coil tube — A tubular coil form. (*Also see* Spool.)

coincidence amplifier—An amplifier which produces no output unless two input pulses are applied simultaneously to the circuit.

coincidence circuit—A circuit that produces a specified output pulse when and only when a specified number (two or more) or combination of input terminals receives pulses within a specified time interval.

coincidence gate—A circuit with the ability to produce an output which is dependent upon a specified type or the coincident nature of the output.

coincident-current selection—The selection of a magnetic core, for reading or writing, by the simultaneous application of two or more currents.

cold cathode—A cathode the operation of which does not depend on its temperature being above the ambient temperature.

cold-cathode tube—An electron tube containing a cathode which will emit electrons without being heated.

cold emission—*See* Field Emission.

cold flow—Change of dimension or distortion, caused by sustained application of a force.

cold-pressure welding—A method of making an electrical connection in which the members to be joined are compressed to the plastic range of the metals.

cold rolling—Rolling a magnetic core alloy into the form of a rod so that the metallic grains are oriented in the long direction of the rod.

cold weld—A joint between two metals (without an intermediate material) produced by the application of pressure only.

colidar — Abbreviation for COherent LIght Detection And Ranging. An optical radar system that uses the direct output from a ruby laser source without further pulse modulation.

collate—To combine two or more similarly ordered sets of items to produce another ordered set. Both the number and the size of the individual items may differ from those of the original sets or their sums.

collator—A device to collate sets of punched cards or other documents into a sequence.

collating sequence—1. In digital computers, the sequence in which the characters acceptable to a computer are ordered. The British term is marshalling sequence. 2. An ordering assigned to a set of items, such that any two sets in that assigned order can be collated.

collector—1. An electrode that collects electrons or ions which have completed their functions within an electron tube. 2. The collector of a transistor is an electrode through which a primary flow of carriers leaves the interelectrode region.

collector capacitance — Depletion-layer capacitance associated with the collector junction of a transistor.

collector-coupled logic—*See* Current-Sourcing Logic.

collector current—The direct current flowing in the collector of a transistor.

collector cutoff—The operating condition of a transistor when the collector current is reduced to the leakage current of the collector-base junction.

collector cutoff current—The minimum current that will flow in the collector circuit of a transistor with zero current in the emitter circuit.

collector efficiency—The ratio, usually expressed in percentage, of useful power output to final-stage power-supply power input of a transistor.

collector family—Set of transistor characteristic curves in which the collector current and voltage are variables.

collector junction—Of a semiconductor device, a junction normally biased in the high-resistance direction, so that the current through the junction can be controlled by the introduction of minority carriers.

collector resistance — Resistance in series with the collector lead in the common-T equivalent circuit of a transistor.

collector rings (slip rings)—Metal rings suitably mounted on an electric machine serving, through stationary brushes bearing thereon, to conduct current into or out of the rotating member.

collector transition capacitance — The capacitance across the collector-to-base transition region of a transistor.

collector voltage—The d-c collector supply voltage applied between the base and collector of a transistor.

collimation—The process of adjusting an instrument so that its reference axis is aligned in a desired direction within a predetermined tolerance.

collimation equipment—Equipment designed specifically for aligning optical equipment.

collimator—An optical device that creates a beam made up of parallel rays of light, used in testing and adjusting certain optical instruments.

collinear array—An antenna array in which half-wave elements are arranged end to end on the same vertical or horizontal line.

color balance—The adjustment of electron-gun emissions to compensate for the difference in the light emitting efficiencies of the three phosphors on the screen of the color picture tube.

color-bar pattern—A test pattern (usually a series of vertical bars, each having a specific hue), used for checking the performance of a color-television receiver.

color breakup—Any fleeting or partial separation of a color picture into its display primary components because of a rapid change in the condition of viewing. For example, fast movement of the head, abrupt interruption of the line of sight, and blinking of the eyes are illustrations of rapid changes in the conditions of viewing.

color burst—Also called reference burst. Approximately nine cycles of the chrominance subcarrier added to the back porch of the horizontal blanking pedestal of the composite color signal and used in the color receiver as a phase reference for the 3.579545-MHz oscillator.

color carrier—*See* Chrominance Subcarrier.

colorcast—A color television broadcast.

color code—A system of colors for specifying the electrical value of a component part or for identifying terminals and leads. Also used to distinguish between cable conductors.

color coder—Also called color encoder. In a color-tv transmitter, that circuit or section which combines the camera signals and the chrominance subcarrier to form the transmitted color picture signal.

color contamination—An error in color rendition due to incomplete separation of the paths carrying different color components of the picture. Such errors can arise in the optical, electronic, or mechanical portions of a color-television system as well as in the electrical portions.

color-coordinate transformation — Computation of the tristimulus values of colors in terms of one set of primaries from the tristimulus values of the same colors in another set of primaries. Such computation may be performed electrically in a color-television system.

color decoder—A section or circuit of a color-television receiver used for deriving the signals for the color-display device from the color-picture signal and the color burst.

color-difference signal—The signal produced when the amplitude of a color signal is reduced by an amount equal to the amplitude of the luminance signal. Color-difference signals are usually designated R-Y, B-Y, and G-Y. In a sense, I and Q signals are also color-difference signals because they are formed when specific proportions of R-Y and B-Y color-difference signals have been combined.

color edging—Spurious color at the boundaries of differently colored areas in a picture.

color encoder—*See* Color Coder.

color fidelity—The degree to which a color television system is capable of faithfully reproducing the colors in an original scene.

color flicker—The flicker which results from fluctuation of both the chromaticity and the luminance.

color fringing—Spurious chromaticity at the boundaries of objects in a color-tv picture. It can be caused by the change in relative position of the televised object from field to field, or by misregistration. Color fringing may cause small objects to appear separated into different colors.

colorimeter—An optical instrument designed to compare the color of a sample with that of a standard sample or a synthesized stimulus. (In a three-color colorimeter, the synthesized stimulus consists of three colors of constant chromaticity but variable luminance.)

colorimetric—The measurement of color characteristics, particularly wavelength and primary-color content.

colorimetry—The technique of measuring color and interpreting the results.

color killer—A stage designed to prevent signals in a color receiver from passing through the chrominance channel during monochrome telecasts.

color match—The condition in which the two halves of a structureless photometric field look exactly the same.

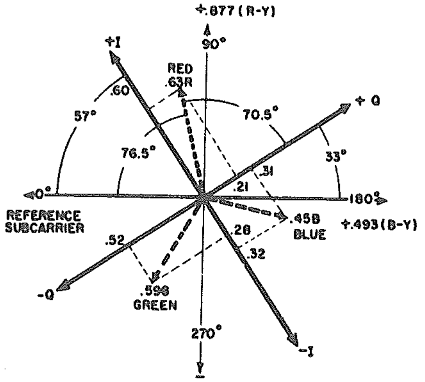
color mixture—Color produced by the combination of lights of different colors. The combination may be accomplished by successive presentation of the components, provided the rate of alternation is sufficiently high; or the combination may be accomplished by simultaneous presentation, either in the same or in adjacent areas, provided they are small enough and close enough together to eliminate pattern effects.

color oscillator—In a color-television receiver, the oscillator operating at the burst frequency of 3.579545 MHz. Its frequency and phase are synchronized by the master oscillator at the transmitter.

color phase—The difference in phase between a chrominance primary signal (I or Q) and the chrominance carrier reference.

color-phase alternation—Periodic changing of the color phase of one or more components of the color-television subcarrier between two sets of assigned values.

color-phase diagram—A vector diagram which denotes the phase difference between the color-burst signal and the chrominance signal for each of the three primary and complementary colors. This diagram also designates vectorially the peak amplitude of the chrominance signal for each of these colors, and the polarities and peak amplitudes of the in-phase and quadrature portions required to form these chrominance signals.



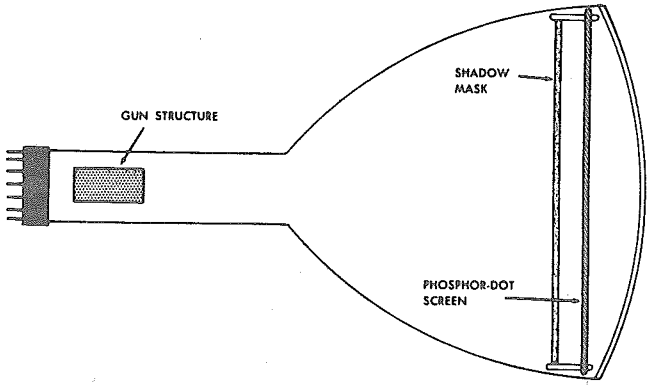
Color-phase diagram.

color-picture signal—1. A signal which represents electrically the three color attributes (brightness, hue, and saturation) of a scene. 2. A combination of the luminance and chrominance signals, excluding all blanking and synchronizing signals.

color-picture tube—An electron tube that provides an image in color by scanning a raster and by varying the intensity at which it excites the phosphors on the screen to produce light of the chosen primary colors.

color primaries—In the color receiver, the saturated colors of definite hue and variable luminance produced by the receiver. These color primaries, when mixed in proper proportions, form other colors.

color purity—Freedom of a color from white light or any colored light not used to produce the desired color.



Color picture tube.

color-purity magnet—A magnet placed in the neck region of a color-picture tube to alter the electron-beam path and thereby improve color purity.

color registration—The accurate superimposing of the red, green, and blue images that are used to form a complete color picture in a color television receiver.

color sampling rate—In a color television system, the number of times per second that each primary color is sampled.

color saturation—The degree to which white light is absent in a particular color. A fully saturated color contains no white light. If 50% of the light intensity is due to the presence of white light, the color is said to have a saturation of 50%.

color sensitivity—The spectral sensitivity of a light-sensitive device such as a phototube or camera tube.

color signal—Any signal at any point in a color-television system, used for wholly or partially controlling the chromaticity values of a color-television picture. This is a general term encompassing many specific connotations, such as are conveyed by the words, "color-picture signal," "chrominance signal," "carrier-color signal," "monochrome signal" (in color television), etc.

color subcarrier—A monochrome signal to which modulation sidebands have been added to convey color information.

color-sync signal—The series of color bursts (pulses of subcarrier-reference signal) applied to the back porch of the horizontal-sync pedestal in the composite video signal.

color-television receiver—A standard monochrome receiver to which special circuits have been added. Phosphors capable of glowing in the three primary colors are used on the special screen. By using these primary colors and mixing them to produce complementary colors, and by varying their intensity, it is possible to reproduce an image in somewhat the original colors.

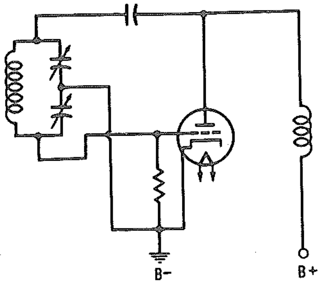
color-television signal—The complete signal used to transmit a color picture. Included are horizontal-, vertical-, and color-sync components.

color temperature—The temperature to which a perfectly black body must be heated to match the color of the source being measured. Color-temperature measurements begin at absolute zero and are expressed in degrees Kelvin.

color transmission—The transmission of color-television signals which can be reproduced with different values of hue, saturation, and luminance.

color triad—One cell of a three-color, phosphor-dot screen of a phosphor-dot, color-picture tube. Each triad contains one dot of each of the three color-producing phosphors.

color triangle—A triangle drawn on a chromaticity diagram to represent the entire range of chromaticities obtainable when the 3 prescribed primaries are added. These are represented by the corners of the triangle.



Colpitts oscillator.

Colpitts oscillator—An electron-tube oscillator comprising a parallel-tuned tank circuit connected between grid and plate. The tank capacitance contains two voltage-dividing capacitors in series, with their common connection at cathode potential. When these two capacitances are the plate-to-cathode and grid-to-cathode capacitances of the tube, the circuit is known as an Ultra-audion oscillator.

column—Also called place. In positional notation, a position corresponding to a given power of the radix. A digit located in any particular column is a coefficient of a corresponding power of the radix.

coma—1. An aberration of spherical lenses, occuring in the case of oblique incidence, when the bundle of rays forming the image is unsymmetrical. The image of a point is comet shaped, hence the name. 2. A cathode-ray tube image defect that makes the spot on the screen appear comet shaped when away from the center of the screen.

comb filter—A type of filter network that is, in effect, a multiple-bandpass design that passes only frequencies within a number of narrow bands, or provides outputs corresponding to each of its passbands. Comb filters are so named because their response characteristics have the appearance of a comb.

combination cable—A cable in which the conductors are grouped in combinations such as pairs and quads.

combination microphone—A microphone consisting of two or more similar or dissimilar microphones combined into one.

combination tones—Frequencies produced in a nonlinear device, such as in an audio amplifier having appreciable harmonic distortion.

combiner — A circuit for mixing video, trigger, and scan data from the synchronizer for the modulation of a link.

combiner circuit—One that combines the luminance and chroma channels with the sync signals in color-television cameras.

combustible—*See* Flammable.

command—1. In a computer, one or more sets of signals which occur as the result of an instruction. (*Also see* Instruction.) 2. An independent signal from which the dependent signals in a feedback-control system are controlled according to the prescribed system relationships. 3. A signal which initiates or triggers an action in the device that receives the signal.

command control—A system whereby functions are performed as the result of a transmitted signal.

command destruct signal—A radio signal for destroying a missile in flight.

command guidance system—A missile guidance system in which both the missile and the target are tracked by radar. The missile is guided by signals transmitted to it while it is in flight. (*Also see* Command Link.)

command link—The portion of a command guidance system used to transmit steering commands to the missile. (*Also see* Command Guidance System.)

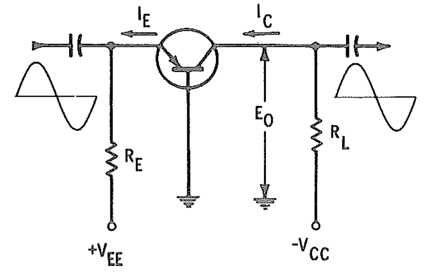
command module—*See* Module.

command net— A communication network which connects an echelon of command with some or all of its subordinate echelons for the purpose of command and control.

command reference—In a servo or control system, the voltage or current to which the feedback signal is compared. As an independent variable, the command reference exercises complete control over the system output.

comment—An expression which explains or identifies a particular step in a routine, but which has no effect on the operation of the computer in performing the instructions for the routine.

commercial test (measuring) equipment—Devices used as "working instruments" selected from suppliers' catalogs as suitable for the user's measuring needs and procured as standard ("off-the-shelf") items. This includes measuring devices installed, intact and in consoles. Devices procured from suppliers but modified by user-imposed specifications, in such a manner as to affect console performance, do not fall into this category.



Common-base amplifier.

common-base amplifier — Also called a grounded-base amplifier. A transistor amplifier in which the base element is common to both the input and the output circuit. It is comparable to the grounded-grid configuration of a triode electron-tube amplifier.

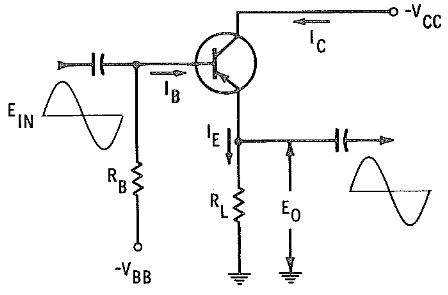
common battery—A system of current supply in which all direct-current energy for a unit of a telephone system is supplied by one source in a central office or exchange.

common-battery office — A central office which supplies transmitter and signal current for its associated stations, and for signaling by the central office equipment from a power source located in the central office.

common business oriented language—Specific language by which business data-processing procedures may be precisely described in a standard form. Intended not only as a means for directly presenting any business program to any suitable computer for which a compiler exists, but also as a means of communicating such procedures among individuals.

common-carrier fixed station—A fixed station that is open to public correspondence.

common-collector amplifier—Also known as an emitter-follower and a grounded-collector amplifier. A transistor amplifier in which the collector element is common to both the input and the output circuit. This configuration is comparable to an electron-tube cathode follower.



Common-collector amplifier.

common communications carrier— A company recognized by an appropriate regulatory agency as having a vested interest in furnishing communications services.

common-emitter amplifier — Also called grounded-emitter amplifier. A transistor amplifier in which the emitter element is common to both the input and the output circuit. This configuration is comparable to a conventional electron-tube amplifier.

common language—A form of representing information which a machine can read and which is common to a group of computers and data-processing machines.

common mode—Signals that are identical with respect to both amplitude and time. Also used to identify the respective parts of two signals that are identical with respect to amplitude and time.

common-mode characteristics—The characteristics pertaining to performance of an operational amplifier where the inverting and noninverting inputs have a common signal.

common-mode gain—The ratio of the common-mode output voltage of a differential amplifier divided by the common-mode input voltage.

common-mode impedance input—The internal impedance between either one of the input terminals of a differential operational amplifier and signal ground.

common-mode input—That signal applied in phase (i.e., common mode) equally to both inputs of a differential amplifier.

common-mode input capacitance — The equivalent capacitance of both inverting and noninverting inputs of an operational amplifier with respect to ground.

common-mode input impedance — The open-loop input impedance of both inverting and noninverting inputs of an operational amplifier with respect to ground.

common-mode input voltage — The maximum voltage that can be applied simultaneously between the two inputs of a differential amplifier and ground without causing damage.

common-mode rejection — Also called in-phase rejection. A measure of how well a differential amplifier ignores a signal which appears simultaneously and in phase at both input terminals (called a common-mode signal). Usually and preferably stated as a voltage ratio, but more often stated in the db equivalent of said ratio at a specified frequency—e.g., "120 db at 60 hertz with 1K source impedance."

common-mode rejection ratio—The ratio of the common-mode input voltage to the output voltage expressed in db. The extent to which a differential amplifier does not provide an output voltage when the same signal is applied to both inputs.

common-mode resistance — The resistance between the input- and output-signal lines or circuit ground. In an isolated amplifier, this is its insulation resistance. (Common-mode resistance has no connection with common-mode rejection.)

common-mode signal — The instantaneous algebraic average of two signals applied to a balanced circuit (i.e., two ungrounded inputs of a balanced amplifier), all signals referred to a common reference.

common-mode voltage—1. The amount of voltage common to both input lines of a balanced amplifier. Usually specified as the maximum voltage which can be applied without breaking down the insulation between the input circuit and ground. (Common-mode voltage has no connection with common-mode rejection.) 2. The voltage on both inputs of a differential input amplifier.

common-mode voltage gain—The ratio of the signal voltage applied at the inputs (in parallel) to the signal voltage between the outputs.

common-mode voltage range—The range of voltage that may be applied to both inputs of an operational amplifier without saturating the input stage. This may limit the output capabilities in the voltage-follower connection.

common-user channels — Communication channels which are available to all authorized agencies for transmission of command, administrative, and logistic traffic.

communication—The transmission of information from one point, person, or equipment to another.

communication band—The band of frequencies due to the modulation (including keying) necessary for a given type of transmission.

communication channel—Part of a radio or wire circuit, or a combination of wire and radio which connects two or more terminals.

communication link—The physical means of connecting one location to another for the purpose of transmitting and receiving information.

communications common carriers — Companies that furnish communications services to the public, regulated by the FCC or appropriate state agencies.

communications receiver — A receiver designed for reception of voice or code signals from stations operating in the communications service.

communication switch — A device used to execute repetitive sequential switching.

communication zone indicator—A device that indicates whether or not long-distance high-frequency broadcasts are successfully reaching their destination.

community antenna television—A television system that receives and retransmits commercial television broadcasts. Microwave transmitters and coaxial cables are used to bring the television signals to subscribers in a community. Abbreviated catv.

commutation—1. A mechanical process of converting the alternating current in the armature of direct-current generators into the direct-current generator output. 2. Sampling of various quantities in a repetitive manner, for transmission over a single channel in telemetering. 3. Repetitive sampling of two or more information channels for transmission over a single link.

commutation capacitors — Cross-connected capacitors in a thyratron inverter. They provide a path such that the start of conduction in one thyratron causes an extinguishing pulse to be applied to the alternate thyratron. Also used in inverter circuits employing semiconductor devices.

commutator—The part of the armature to which the coils of a motor are connected. It consists of wedge-shaped copper segments arranged around a steel hub and insulated from it and from one another. The motor brushes ride on the outer edges of the commutator bars and thereby connect the armature coils to the power source.

compactron—An electron tube based on a building-block concept which involves the standardizing of basic tube sections, diodes, triodes, pentodes; clipping them together as required; and sealing them in a single envelope.

compander—A combination comprised of a compressor at one point in a communication path to reduce the volume range of signals, followed by an expander at another point to improve the ratio of the signal to the interference entering the path between the compressor and expander.

companding—A process in which compression is followed by expansion. Companding is often used for noise reduction, in which case the compression is applied before the noise exposure and the expansion afterward.

compandor—*See* Compander.

companion keyboard — A remote keyboard connected by a multiwire cable to an ordinary keyboard and able to operate it.

comparator—A circuit which compares two signals and supplies an indication of agreement or disagreement.

compare—A computer operation in which two quantities are matched for the purpose of discovering their relative magnitudes or algebraic values.

comparison bridge—A type of voltage-comparison circuit resembling a four-arm electrical bridge. The elements are so arranged that if a balance exists in the circuit, a zero error signal is derived.

compatible IC—A hybrid IC in which the active circuit element is within the silicon planar integrated structure. A passive network, which may be separately optimized, is deposited onto its insulating surface to complete the IC device.

compatible monolithic integrated circuit—A device in which passive components are deposited by thin-film techniques on top of a basic silicon-substrate circuit containing the active components and some passive parts. *Also see* All-Diffused Monolithic Integrated Circuit.

compatibility—1. That property of a color-television system which permits typical, unaltered monochrome receivers to receive substantially normal monochrome from the transmitted signal. 2. In stereo, a system usable with a monophonic program source, or a stereo program that can be reproduced monophonically on a monophonic system.

compensated amplifier — A broad-band amplifier the frequency range of which is extended by the proper choice of circuit constants.

compensated-impurity resistor—A diffused-layer resistor into which are introduced additional N- and P-type impurities.

compensated-loop direction finder—A direction finder employing a loop antenna and a second antenna system to compensate for polarization error.

compensated semiconductor—A semiconductor in which one type of impurity or imperfection (donor) partially cancels the electrical effects of the other (acceptor).

compensated volume control—*See* Loudness Control.

compensating filter—A filter used to alter the spectral emission of an emulsion to a specified response to different wavelengths.

compensation — The controlling elements which compensate for or offset the undesirable characteristics of the process to be controlled in a system.

compensation signal—A signal recorded on the tape, along with the computer data and on the same track as the data; this signal is used during the playback of data to electrically correct for the effects of tape-speed errors.

compensation theorem—An impedance in a network may be replaced by a generator of zero internal impedance, the generated voltage of which at any instant is equal to the instantaneous potential difference produced across the replaced impedance by the current flowing through it.

compensator—1. In a direction finder, the portion which automatically applies to the direction indication all or part of the correction for the deviation. 2. An electronic circuit for altering the frequency response of an amplifier system to achieve a specified result. This refers to record equalization or loudness correction.

compile — To bring digital-computer programming subroutines together into a main routine or program.

compiler—An automatic coding system in a computer which generates and assembles a program from instructions written by a programmer.

compiling routine — A routine by means of which a computer can itself construct the program used to solve a problem.

complement—1. In an electronic computer, a number the representation of which is derived from the finite positional notation of another by one of the following rules:

True complement—Subtract each digit from 1 less than the base; then add 1 to the least significant digit and execute all required carries.

Base minus 1's complement—Subtract each digit from 1 less than the base (e.g., "9's complement" in the base 10, "1's complement" in the base 2, etc.)

2. To form the complement of a number. (In many machines, a negative number is represented as a complement of the corresponding positive number.)

complementary colors—Two colors are complementary if, when added together in proper proportion such as by projection, they produce white light.

complementary rectifier—Half-wave rectifying circuit elements which are not self-saturating rectifiers in the output of a magnetic amplifier.

complementary-symmetry circuit — An arrangement of PNP and NPN transistors that provides push-pull operation from one input signal.

complementary tracking—A system of interconnection of two or more devices in which one (the master) operates to control the others (the slaves).

complementary transistor amplifier — An amplifier that utilizes the complementary symmetry of NPN and PNP transistors.

complementary transistor logic—A digital logic circuit configuration making use of a complementary transistor emitter coupled AND-OR gate. Basically a two-level diode gate using simultaneous NPN and PNP action.

complementary transistors — Two transistors of opposite conductivity (PNP and NPN) that are operated in the same functional unit.

complementary wave—A wave brought into existence at the ends of a coaxial cable or two-conductor transmission lines, or any discontinuity along the line.

complementary wavelength — The wavelength of light of a single frequency. When combined with a sample color in suitable proportions, the wavelength matches the reference-standard light.

complementor—A circuit or device that produces a Boolean complement. A NOT circuit.

complete carry—A system of executing the carry process in a computer. All carries, and any other carries to which they give rise, are allowed to propagate to completion in this system.

complex components—Indivisible and nonrepairable components having more than one function.

complex function—An integrated device in which three or more circuits are integral to a single silicon chip. In addition, the circuits are interconnected on the chip itself to form some electronic function at a higher level of organization than a single circuit. The interconnection pattern for the function is predetermined by the fixed mask; no wiring discretion is available for yield purposes. The input and outputs of all the circuits are not normally exposed to the package terminals. An example of a complex function would be a full adder or a multibit serial shift register.

complex parallel permeability — The complex relative permeability measured under stated conditions on a core with the aid of a coil. The parameter characterizing the induction is the impedance of the coil when placed on the core, expressed as a parallel connection of reactance and resistance. The parameter characterizing the field strength is the reactance the coil would have if placed on a core of the same dimensions but with unity relative permeability, the distribution of the magnetic field being identical in both cases. The coil should have negligible copper losses.

complex permeability—Under stated conditions, the complex quotient of the moduli of the parallel vectors representing induction and field strength in a material. One of the moduli varies sinusoidally with time, and the component chosen from the other modulus varies sinusoidally at the same frequency.

complex series permeability—The complex relative permeability measured under stated conditions on a core with the aid of a coil. The parameter characterizing the induction in the core is the impedance of the coil when placed on the core, expressed as a series connection of reactance and resistance. The parameter characterizing the field strength is the reactance this coil would have if placed on a core of the same dimensions but with unity relative permeability. The coil should have negligible copper losses, etc.

complex steady-state vibration—A periodic vibration of more than one sinusoid. It includes repeating square waves, sawtooth waves, etc., because these waveforms can be expressed in terms of a Fourier series of sinusoidal terms.

complex tone—A sound wave produced by the combination of simple sinusoidal components of different frequencies. A sound sensation characterized by more than one pitch.

complex wave—A periodic wave made up of a combination of several frequencies or several sine waves superimposed on one another.

complex-wave generator — A device which generates a nonsinusoidal signal having a desired repetitive characteristic and waveform.

compliance—1. The reciprocal of stiffness—i.e., the ability to yield or flex. 2. The ease with which a phonograph stylus responds to an outside force. 3. The mechanical and acoustical equivalent of capacitance.

compliance extension—A form of master/slave interconnection of two or more current-regulated supplies to increase their output-voltage range through series connection.

compliance range — The range of voltage needed to sustain a given constant current throughout a range of load resistances.

compliance voltage—The output voltage of a constant-current supply.

compliance voltage range—The output voltage range of a d-c power supply operating in a constant-current mode.

component — 1. An essential functional part of a subsystem or equipment. It may be any self-contained element with a specific function, or it may consist of a combination of parts, assemblies, accessories, and attachments. 2. In vector analysis, one of the parts of a wave, voltage, or current considered separately.

component density—The volume of a circuit assembly divided by the total number of discrete circuit components utilized, usually expressed in components per cubic foot.

component layout—The physical arrangement of the components in a chassis or printed circuit.

component operating hours — A unit of measurement for the period of successful operation of one or more components (of a specified type) which have endured a given set of environmental conditions.

component stress—Those factors of usage or test, such as voltage, power, temperature, frequency, etc., which tend to affect the failure rate of component parts.

composite cable—A cable in which conductors of different gages or types are combined under one sheath.

composite circuit—A circuit which can be used simultaneously for telephony and direct-current telegraphy or signaling, the two being separated by frequency discrimination.

composite color signal—The color-picture signal plus all blanking and synchronizing signals. Includes luminance and chrominance signals, vertical- and horizontal-sync pulses, vertical- and horizontal-blanking pulses, and the color-burst signal.

composite color sync—The signal comprising all the sync signals necessary for proper operation of a color receiver. Includes the deflection sync signals to which the color sync signal is added in the proper time relationship.

composite conductor—Two or more strands of different metals, such as aluminum and steel or copper and steel, assembled and operated in parallel.

composite controlling voltage—The voltage of the anode of an equivalent diode, combining the effects of all individual electrode voltages in establishing the space-charge limited current.

composited circuit—A circuit which can be used simultaneously for telephony and for direct-current telegraphy or signaling, separation between the two being accomplished by frequency discrimination.

composite filter—A filter with two or more sections.

composite guidance system—A guidance system using a combination of more than one individual guidance system.

composite picture signal—The television signal produced by combining a blanked picture signal with the sync signal.

composite video signal—The complete video signal. For monochrome, it consists of the picture signal and the blanking and synchronizing signals. For color, color-synchronizing signals and color-picture information are added.

composite wave filter—A combination filter consisting of two or more low-pass, high-pass, bandpass, or band-elimination filters.

composition resistor—*See* Carbon Resistor.

compound-connected transistor—Two transistors which are combined to increase the current amplification factor at high emitter currents. This combination is generally employed in power-amplifier circuits.

compound-filled transformer — A transformer which is contained within a case and in which the structural insulating material is supplemented by submergence in a solid or semisolid insulating material introduced into the case in a fluid state.

Composite picture signal.

compound horn—An electromagnetic horn of rectangular cross section. The four sides of the horn diverge in such a way that they coincide with or approach four planes, with the provision that the two opposite planes do not intersect the remaining planes.

compound modulation—*See* Multiple Modulation.

compound-wound motor—A d-c motor having two separate field windings. One, usually the predominant field, is connected in parallel with the armature circuit and the other is connected in series.

compressed-air loudspeaker—A loudspeaker that has an electrically actuated valve to modulate a stream of compressed air.

compression—A process in which the effective amplification of a signal is varied as a function of the signal magnitude, the effective gain being greater for small than for large signals. In television, the reduction in gain at one level of a picture signal with respect to the gain at another level of the same signal.

compressional wave—In an elastic medium, a wave which causes a change in volume of an element of the medium without rotation of the element.

compression driver unit—A speaker driver unit that does not radiate directly from the vibrating surface. Instead, it requires acoustic loading from a horn which connects through a small throat to an air space adjacent to the diaphragm.

compression ratio—The ratio between the magnitude of the gain (or amplification) at a reference signal level and its magnitude at a higher stated signal level.

compressor—A transducer which, for a given amplitude range of input voltages, produces a smaller range of output voltages. In one important type of compressor, the envelope of speech signals is used to reduce their volume range.

compromise network—In a telephone system, a network used in conjunction with a hybrid coil to balance a subscriber's loop. The network which is adjusted for an average loop length, an average subscriber's set, or both, and gives compromise (not precision) isolation between the two directional paths of the hybrid coil.

Compton effect — The elastic scattering of photons by electrons. Because the total energy and momentum are conserved in the collisions, the wavelength of the scattered radiation undergoes a change that depends on the scattering angle.

computer — Any device, usually electronic, capable of accepting information, comparing, adding, subtracting, multiplying, dividing, and integrating this information, and then supplying the results of these processes in acceptable form.

computer code — Also called machine language. The code by which data are represented within a computer system. An example is a binary-coded decimal.

computing—To perform basic and more involved mathematical processes of comparing, adding, subtracting, multiplying, dividing, integrating, etc.

computing machine — An automatic device which carries out well defined mathematical operations.

concatenate—To link together or unite in a series.

concatenation — The joining or linking of sets or series.

concave—Curved inward.

concentrated-arc lamp—A type of low-voltage arc lamp having nonvaporizing electrodes sealed in an atmosphere of inert gas and producing a small, brilliant, incandescent cathode spot.

concentration gradient—A difference in carrier concentration (holes or free electrons) from point to point in a semiconductor.

concentric cable—*See* Coaxial Line.

concentric groove—*See* Locked Groove.

concentric-lay conductor—A conductor composed of a central core surrounded by one or more layers of helically laid wires. In the most common type of concentric-lay conductor, all wires are of the same size, and the central core is a single wire.

concentric line—*See* Coaxial Line.

concentric stranding—A method of stranding wire in which the final wire is built up in layers such that the inner diameter of a succeeding layer always equals the outer diameter of the underlying layer.

concentric-wound coil—A coil with two or more insulated windings which are wound one over the other.

concurrent processing — The ability of a computer to work on more than one program at the same time.

condensed mercury temperature—The temperature of a mercury-vapor tube, measured on the outside of the tube envelope, in the region where the mercury is condensing in a glass tube or at a designated point on a metal tube.

condenser—*See* Capacitor.

condenser antenna—*See* Capacitor Antenna.

condenser microphone — *See* Electrostatic Microphone.

condenser speaker—*See* Electrostatic Speaker.

conditional—1. In a computer, subject to the result of a comparison made during computation. 2. Subject to human intervention.

conditional jump—Also called conditional transfer of control. An instruction to a computer which will cause the proper one of two (or more) addresses to be used in obtaining the next instruction, depending on some property of one or more numerical expressions or other conditions.

conditional transfer of control—*See* Conditional Jump.

Condor—A c-w navigational system, similar to benito, which automatically measures bearing and distance from a single ground station and displays them on a cathode-ray indicator. The distance is determined by phase comparison, and the bearing, by automatic direction finding.

conductance—Symbolized by G or g. 1. In an element, device, branch, network, or system, the physical property that is the factor by which the square of an instantaneous voltage must be multiplied to give the corresponding energy lost by dissipation as heat or other permanent radiation, or by loss of electromagnetic energy from the circuit. 2. The real part of admittance.

conducted heat—Thermal energy transferred by thermal conduction.

conducted interference—Any unwanted electrical signal conducted on the power lines supplying the equipment under test, or on lines supplying other equipment to which the one under test is connected.

conduction—The transmission of heat or electricity through or by means of a conductor.

conduction band—In a semiconductor, a partially filled energy band in which electrons can move freely, allowing the material to carry an electric current.

conduction current—The power flow parallel to the direction of propagation, expressed in mhos/meter.

conduction-current modulation—1. Periodic variations in the conduction current passing a point in a microwave tube. 2. The process of producing such variations.

conduction electrons—The electrons which are free to move under the influence of an electric field in the conduction band of a solid.

conduction error—The error in a temperature transducer due to heat conduction between the sensing element and the mounting to the transducer.

conduction field—Energy which surrounds a conductor when an electric current is passed through the conductor, and which, because of the difference in phase between the electrical field and magnetic field set up in the conductor, cannot be detached from the conductor.

conductive gasket—A special highly resilient gasket used to reduce r-f leakage in shielding which has one or more access openings.

conductive material—A material in which a relatively large conduction current flows when a potential is applied between any two points on or in a body constructed from the material. Metals and strong electrolytes are examples of conductors.

conductive pattern—The arrangement or design of the conductive lines on a printed-circuit board.

conductivity—1. The conductance between opposite faces of a unit cube of material. The volume conductivity of a material is the reciprocal of the volume resistivity. 2. The ability of a material to conduct current. The reciprocal of resistivity.

conductivity modulation — The change in conductivity of a semiconductor as the charge-carrier density is varied.

conductivity - modulation transistor — A transistor in which the active properties are derived from minority-carrier modulation of the bulk resistivity of the semiconductor.

conductor—1. A bare or insulated wire or combination of wires not insulated from one another, suitable for carrying an electric current. 2. A body of conductive material so constructed that it will serve as a carrier of electric current.

conduit — A tubular raceway for holding wires or cables designed and used expressly for this purpose.

conduit wiring—Wiring carried in conduits and conduit fittings.

cone—The cone-shaped paper or fiber diaphragm of a speaker.

cone of nulls—A conical surface formed by directions of negligible radiation.

cone of silence — An inverted cone-shaped space directly over the aerial towers of some radio beacons. Within the cone, signals cannot be heard or will be greatly reduced in volume.

confetti—Flecks or streaks of color caused by tube noise in the chrominance amplifier. Because of its colors, confetti is much more noticeable than snow in a black-and-white picture. The chrominance amplifier is therefore cut off during a monochrome program.

confidence—1. The likelihood, expressed in per cent, that a statement is true. 2. The degree of assurance that the stated failure rate has not been exceeded.

confidence factor—The percentage figure expressing confidence level.

confidence interval—A range of values believed to include, with a preassigned degree of confidence, the true characteristic of the lot.

confidence level—The probability (expressed as a percentage), that a given assertion is true or that it lies within certain limits calculated from the date. 2. A degree of certainty.

confidence limits—Extremes of a confidence interval within which there is a designated chance that the true value is included.

configuration—1. The relative arrangement of parts (or components) in a circuit. 2. A listing of the names and/or serial numbers of the assemblies which comprise an equipment.

conformance error — The deviation of a calibration curve from a specified curve line.

conical horn—A horn the cross-sectional area of which increases as the square of the axial length.

conical scanning—A form of scanning in which the beam of a radar unit describes a cone, the axis of which coincides with that of the reflector.

conjugate branches—Any two branches of a network in which a driving force impressed

on one branch does not produce a response in the other.

conjugate bridge—A bridge in which the detector circuit and the supply circuits are interchanged, compared with a normal bridge.

conjugate impedance — An impedance the value of which is the conjugate of a given impedance. For an impedance associated with an electric network, the conjugate is an impedance with the same resistance component and a negative reactive component of the original.

connected—A network is connected if, between every pair of nodes of the network, there exists at least one path composed of branches of the network.

connection — 1. The attachment of two or more component parts so that conduction can take place between them. 2. The point of such attachment.

connection diagram—A diagram showing the electrical connections between the parts comprising an apparatus.

connector—A coupling device which provides an electrical and/or mechanical junction between two cables, or between a cable and a chassis or enclosure.

connector assembly—The combination of a mated plug and receptacle.

conoscope—An instrument for determining the optical axis of a quartz crystal.

consequent poles—Additional magnetic poles present at other than the ends of a magnetic material.

consol—*See* Sonne.

console—1. A cabinet for a radio or television receiver that stands on the floor rather than on a table. 2. Main operating unit in which indicators and general controls of a radar or electronic group are installed.

console operator — A person who monitors and controls an electronic computer by means of a central control unit or console.

consonance — Electrical or acoustical resonance between bodies or circuits not connected directly together.

constant — An unvarying or fixed value or data item.

constant-amplitude recording—The disc-recording characteristic in which the groove displacement is directly proportionate to the signal amplitude.

constant current — A current that does not undergo a change greater than the required precision of the measurement when the impedance of the generator is halved.

constant-current characteristic—The relationship between the voltages of two electrodes, the current to one of them as well as all other voltages being maintained constant.

constant-current modulation — Also called Heising modulation. A system of amplitude modulation in which the output circuits of the signal amplifier and carrier-wave generator or amplifier are directly and conductively coupled by a common inductor. The inductor has an ideally infinite impedance to the signal frequencies and therefore maintains the common plate-supply current of the two devices constant. The signal-frequency voltage thus appearing across the common inductor also modulates the plate supply to the carrier generator or amplifier, with corresponding modulation of the carrier output.

constant-current power supply — A regulated power supply which acts to keep its output current constant in spite of changes in load, line, or temperature. Thus, for a change in load resistance, the output current remains constant to a first approximation, while the output voltage changes by whatever amount necessary to accomplish this.

constant-current transformer — A transformer that automatically maintains a constant current in its secondary circuit under varying conditions of load impedance when supplied from a constant-potential source.

constant-delay discriminator — *See* Pulse Demoder.

constant-K filter—An image-parameter filter comprising a tandem connection of a number of identical prototype L-section filters. Each adjacent pair of L-sections together forms either a T- or π-network. The product of the series and shunt impedances is a constant that is independent of frequency.

constant-K network—A ladder network in which the product of its series and shunt impedances is independent of frequency within the range of interest.

constant-luminance transmission—A type of transmission in which the transmission primaries are a luminance primary and two chrominance primaries.

constant-power-dissipation line — A line superimposed on the output static characteristic curves and representing the points of collector voltage and current, the product of which represents the maximum collector power rating of a particular transistor.

constant-resistance network — A network that will reflect a constant resistance to the output circuit of the driving amplifier when terminated in a resistive load. Loudspeakers do not reflect a constant impedance; therefore, an amplifier does not see a constant resistance. This disadvantage may be somewhat compensated for by the use of negative feedback by the amplifier.

constant-velocity recording — The disc-recording characteristic in which the groove displacement is inversely proportionate to the signal frequency.

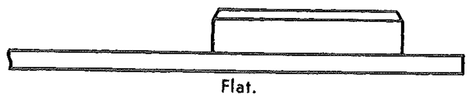
constant voltage — A voltage that does not undergo a change greater than the required precision of the measurement when the impedance of the generator is doubled.

constant-voltage/constant-current (cv/cc) output characteristic—A regulated power supply which acts as a constant-voltage source for comparatively large load resistances and as a constant-current source for comparatively small load resistances.

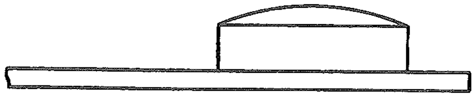
constant-voltage power supply — A regulated power supply which acts to keep its output voltage constant in spite of changes in load, line, or temperature. Thus, for a change in load resistance, the output voltage of this type of supply remains constant to a first approximation, while the output current changes by whatever amount necessary to accomplish this.

constant-voltage transformer — A transformer delivering a fixed predetermined voltage over a limited range of input voltage variations (e.g. 95-125 volts).

consumer's reliability risk—The risk to the consumer that a product will be accepted by a reliability test when the reliability of the product is actually below the value specified for rejection.



Flat.



Convex.

Contacts (side view).

contact—1. One of the current-carrying parts of a relay, switch, or connector that are engaged or disengaged to open or close the associated electrical circuits. 2. (v) To join two conductors or conducting objects in order to provide a complete path for current flow. 3. (n) The juncture point to provide the complete path.

contact-actuation time—The time required for any specified contact on the relay to function. When not otherwise specified, it is the initial actuation time. For some purposes, it is preferable to use either the final or effective actuation time.

contact arc — The electrical (current) discharge that occurs between mating contacts when the circuit is being disestablished.

contact area — The common area between two conductors or a conductor and a connector through which the flow of electricity takes place.

contact arrangement—The combination of contact forms that make up the entire relay-switching structure.

contact bounce—The uncontrolled making and breaking of contact when the relay contacts are closed.

contact chatter—The undesired vibration of mating contacts during which there may or may not be actual physical contact opening. If there is no actual opening but only a change in resistance, it is referred to as dynamic resistance, and it appears as "grass" on the screen of an oscilloscope having adequate sensitivity and resolution.

contact combination—1. The total assembly of contacts on a relay. 2. Sometimes used for contact form.

contact emf — A small voltage established whenever two conductors of different materials are brought into contact.

contact follow—The displacement of a stated point on the contact-actuating member following the initial closure of a contact.

contact force—1. The amount of force exerted by one of a pair of closed contacts on the other. 2. The force exerted by the moving mercury on a stationary contact or electrode in a mercury switch.

contact gap—Also called contact separation. The distance between a pair of mating relay contacts when they are open.

contact length—The length of travel of one contact while touching another contact during the assembly or disassembly of a connector.

contact load—The electrical power demands encountered by a contact set in any particular application.

contact microphone—A microphone designed to pick up mechanical vibrations directly from the sound source and convert them into corresponding electrical currents or voltages.

contact modulator — A switch used to produce modified square waves having the same frequency as, and a definite phase relationship to, a driving sine wave. Also called electromechanical chopper.

contact noise—The random fluctuation of voltage across a junction through which current is flowing from one solid to another.

contactor—A heavy-duty relay used to control electrical circuits.

contactor alarm—A signal calling attention to lowered pressure in a cable gas-pressure system.

contact potential—Also called volta effect. The difference of potential that exists when two dissimilar, uncharged metals are placed in contact. One becomes positively charged and the other negatively charged, the amount of potential depending on the nature of the metals.

contact-potential difference—The difference between the work functions of two materials, divided by the electronic charge generated by them.

contact pressure — The amount of pressure holding a set of contacts together.

contact rating — The electrical power-handling capability of relay or switch contacts under specified environmental conditions and for a prescribed number of operations.

contact rectifier—A rectifier consisting of two different solids in contact. Rectification is due to the greater conductivity across the contact in one direction than in the other.

contact resistance—Total electrical resistance of a contact system, such as the resistance of a relay or a switch measured at the terminals. Usually this resistance is only a fraction of an ohm.

contact retention—The minimum axial load a contact in a connector can withstand in either direction while remaining firmly fixed in its normal position in the insert.

contacts — In a relay, the current-carrying parts that engage or disengage to open or close electrical circuits.

contact separation—The maximum distance between the stationary and movable contacts when the circuit is broken.

contact spring—1. A current-carrying spring to which the contacts are fastened. 2. A non-current-carrying spring that positions and tensions a contact-carrying member.

contact wetting—The coating of a contact surface with an adherent film of mercury.

contact wipe—The sliding or tangential motion between two touching contact surfaces.

contaminated—Made radioactive by addition of a radioactive material.

contents—The information stored in any part of the computer memory.

Continental code—*See* International Morse Code.

continuity—1. A continuous path for the flow of current in an electric circuit. 2. In radio broadcasting, the prepared copy from which the spoken material is presented.

continuity test—An electrical test for determining whether a connection is broken.

continuity writer—In radio broadcasting, the person who writes the copy from which the spoken material is presented.

continuous carrier — A carrier over which transmission of information is accomplished by means which do not interrupt the carrier.

continuous commercial service—*See* CCS.

continuous-duty rating—The rating applied to equipment if operated for an indefinite length of time.

continuously loaded cable — A submarine cable in which the conductors are continuously loaded.

continuous power—The power an amplifier is capable of delivering for at least 30 seconds with a sine-wave signal.

continuous rating—The rating that defines the load which can be carried for an indefinite length of time.

continuous recorder—A recorder that makes its record on a continuous sheet or web rather than on individual sheets.

continuous spectrum—The spectrum which exhibits no structure and appears to represent a continuous variation of wavelength from one to the other.

continuous variable—A variable that may assume any value within a defined range.

continuous-wave radar—A system in which a transmitter sends out a continuous flow of radio energy to the target, which reradiates (scatters) the energy intercepted and returns a small fraction to a receiving antenna.

continuous waves — Electromagnetic waves generated as a continuous train of identical oscillations. They can be interrupted according to a code, or modulated in amplitude, frequency, or phase in order to convey information. Abbreviated cw.

continuous-wave tracking system—A tracking system which operates by keeping a continuous radio beam on a target and determining its behavior from changes in the antenna necessary to keep the beam on the target.

contrahelical—In the wire and cable industry the term is used to mean the direction of a layer with respect to the previous layer. Thus it would mean a layer spiraling in an opposite direction from the preceding layer within a wire or cable.

Contran — A computer-programming language in which instructions are written at a compiler level, thereby eliminating the need for translation by a compiling routine.

contrast—1. The actual difference in density between the highlights and the shadows. Contrast is not concerned with the magnitude of density, but only with the difference in densities. 2. Amplitude ratio between picture white and picture black. 3. Ratio between the maximum and minimum brightness values in a picture. 4. In optical character recognition, the differences between the color or shading of the printed material on a document and the background on which it is printed.

contrast control—A method of adjusting the contrast in a television picture by changing the amplitude of the video signal.

contrast range — The ratio between the whitest and blackest portions of a television image.

contrast ratio—Ratio of the maximum to the minimum luminance values in a television picture or a portion thereof.

control—Also called a control circuit. 1. In a digital computer, those parts which carry out the instructions in proper sequence, interpret each instruction, and apply the proper signals to the arithmetic unit and other parts in accordance with the interpretation. 2. Sometimes called a manual control. In any mechanism, one or more components responsible for interpreting and carrying out manually initiated directions. 3. In some business applications, a mathematical check. 4. In electronics, a potentiometer or variable resistor.

control ampere turns—The magnitude and polarity of the control magnetomotive force required for operation of a magnetic amplifier at a specified output.

control card—In computer programming, a card containing input data or parameters for a specific application of a general routine.

control characteristic—1. A plot of the load current of a magnetic amplifier as a function of the control ampere turns for various loads and at the rated supply voltage and frequency. 2. The relationship, usually shown by a graph, between the critical grid voltage and the anode voltage of a tube.

control circuits—In a digital computer, the circuits which carry out the instruction in proper sequence, interpret each instruction, and apply the proper commands to the arithmetic element and other circuits in accordance with the interpretation.

control-circuit transformer — A voltage transformer utilized to supply a voltage suitable for the operation of control devices.

control-circuit voltage — The voltage provided for the operation of shunt-coil magnetic devices.

control compartment — A space within the base, frame, or column of a machine used for mounting the control panel.

control counter — In a computer, a device which records the storage location of the instruction word to be operated on following the instruction word in current use.

control data — In a computer, one or more items of data used to control the identification, selection, execution, or modification of another routine, record file, operation, data value, etc.

control electrode—An electrode on which a voltage is impressed to vary the current flowing between other electrodes.

control field—In a sequence of similar items of computer information, a constant location where control information is placed.

control grid—The electrode of a vacuum tube, other than a diode, upon which a signal voltage is impressed to regulate the plate current.

control-grid bias—The average direct-current voltage between the control grid and cathode of a vacuum tube.

control-grid plate transconductance—The ratio of the amplification factor of a vacuum tube to its plate resistance, combining the effect of both into one term.

controlled avalanche device — A semiconductor device that has very specific maximum and minimum avalanche-voltage characteristics and is also able to operate and absorb momentary power surges in this avalanche region indefinitely without damage.

controlled-carrier modulation — Also called variable-carrier or floating-carrier modulation. A modulation system in which the carrier is amplitude-modulated by the signal frequencies, and also in accordance with the envelope of the signal, so that the modulation factor remains constant regardless of the amplitude of the signal.

controlled rectifier—1. A rectifier employing grid-controlled devices such as thyratrons or ignitrons to regulate its own output current. 2. Also called an scr (silicon-controlled rectifier). A four-layer PNPN semiconductor which functions like a grid-controlled thyratron.

controller—An element or group of elements that take data proportional to the difference between input and output of a device or system and convert these data into power used to restore agreement between input and output.

control locus—A curve which shows the critical value of grid bias for a thyratron.

control panel — A panel having a systematic arrangement of terminals used with removable wires to direct the operation of a computer or punched-card equipment.

control-power disconnecting device—A disconnective device such as a knife switch, circuit breaker, or pullout fuse block used for the purpose of connecting and disconnecting, respectively, the source of control power to and from the control bus or equipment.

control ratio—1. The ratio of the change in anode voltage to the corresponding change in critical grid voltage of a gas tube, with all other operating conditions maintained constant. 2. Also called programming coefficient. The required range in control resistance of a regulated power supply to produce a 1-volt change in output voltage. Expressed in ohms per volt.

control register—In a digital computer, the register that stores the current instruction governing the operation of the computer for a cycle. Also called instruction register.

control section—*See* Control Unit.

control sequence—In a computer, the normal order of execution of instructions.

control tape—In a computer, a paper or plastic tape used to control the carriage operation of some printing output devices. Also called carriage tape.

control unit—That section of an automatic digital computer that directs the sequence of operations, interprets coded instructions, and sends the proper signals to the other computer circuits to carry out the instructions. Also called control section.

control-voltage winding—The motor winding which is excited by a varying voltage at a time phase difference from the voltage applied to the fixed voltage windings of a servomotor.

control winding—In a saturable reactor, the winding used for applying a controlling magnetomotive premagnetization force to the saturable-core material.

convection—The motion in a fluid as a result of differences in density and the action of gravity.

convection cooling—A method of heat transfer which depends on the natural upward movement of the air warmed by the heat dissipated from the device being cooled.

convection current—The amount of time required for a charge in an electron stream to be transported through a given surface.

convection-current modulation — 1. The time variation in the magnitude of the convection current passing through a surface. 2. The process of producing such a variation.

convergence—The condition in which the electron beams of a multibeam cathode-ray tube intersect at a specified point.

convergence coil—One of the two coils associated with an electromagnet, used to obtain dynamic beam convergence in a color-television receiver.

convergence control—A variable resistor in the high-voltage section of a color-television receiver. It controls the voltage applied to the three-gun picture tube.

convergence electrode — An electrode the electric field of which causes two or more electron beams to converge.

convergence magnet—A magnet assembly the magnetic field of which causes two or more electron beams to converge.

convergence phase control—A variable resistor or inductance for adjusting the phase of the dynamic convergence voltage in a color-tv receiver employing a three-gun picture tube.

convergence surface—The surface generated by the point at which two or more electron beams intersect during the scanning process in a multibeam cathode-ray tube.

conversion efficiency—1. The ratio of a-c output power to the d-c input power to the electrodes of an electron tube. 2. The ratio of the output voltage of a converter at one frequency to the input voltage at some other frequency. 3. In a rectifier, the ratio of d-c output power to a-c input-power.

conversion gain—1. The ratio of the intermediate-frequency output voltage to the input-signal voltage of the first detector of a superheterodyne receiver. 2. The ratio of the available intermediate-frequency power output of a converter or mixer to the available radio-frequency power input.

conversion loss—The ratio of available input power to available output power under specified test conditions.

conversion time — The length of time required by a computer to read out all the digits in a given coded word.

conversion transconductance — The magnitude of the desired output-frequency component of current divided by the magnitude of the input-frequency component of voltage when the impedance of the output external termination is negligible for all frequencies which may affect the result.

conversion transducer—One in which the signal undergoes frequency conversion. The gain or loss is specified in terms of the useful signal.

conversion voltage gain (of a conversion transducer)—With the transducer inserted between the input-frequency generator and the output termination, the ratio of the magnitude of the output-frequency voltage across the output termination to the magnitude of the input-frequency voltage across the input termination of the transducer.

convert — To change information from one form to another without changing the meaning, e.g., from one number base to another.

converter—1. In a superheterodyne radio receiver, the section which converts the desired incoming r-f signal into a lower carier frequency known as the intermediate frequency. 2. A rotating machine consisting of an electric motor driving an electric generator, used for changing alternating current to direct current. 3. A facsimile device that changes the type of modulation delivered by the scanner. 4. Generally called a remodulator. A facsimile device that changes amplitude modulation to audio-frequency-shift modulation. 5. Generally called a discriminator. A device that changes audio-frequency-shift modulation to amplitude modulation. 6. A conversion transducer in which the output frequency is the sum or difference of the input frequency and an integral multiple of the local-oscillator frequency. 7. A device that accepts an input that is a function of maximum voltage and time, and converts it to an output that is a function of maximum voltage only. 8. *See* Shaft Position Encaser. 9. A device capable of converting impulses from one mode to another, such as analog to digital, or parallel to serial, or one code to another.

converter tube — A multielement electron tube that combines the mixer and local-oscillator functions of a heterodyne conversion transducer.

converter unit—The unit of a radar system in which the mixer of a superheterodyne receiver and usually two stages of intermediate-frequency amplification are located. Performs a preamplifying operation.

converting—Changing data from one form to another to facilitate its transmission, storage, or manipulation of information.

convex—Curved outward.

Cook system—An early stereo-disc recording technique in which the two channels were recorded simultaneously with two cutters on different portions (bands) of a record as concentric spirals. The playback equipment consisted of two pickups mounted side by side so that each played at the correct spot on its own band.

Coolidge tube—An X-ray tube in which the electrons are produced by a hot cathode.

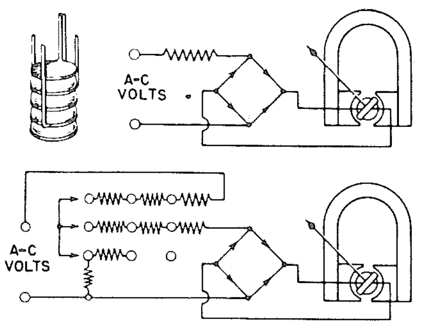
coordinated transpositions—Transpositions which are installed in either electric supply or communication circuits, or in both, for the purpose of reducing inductive coupling, and which are located effectively with respect to the discontinuities in both the electric supply and communication circuit.

coordinater indexing—1. In a computer, a system in which individual documents are indexed by descriptors of equal rank so that a library can be searched for a combination of one or more descriptors. 2. A computer indexing technique in which the coupling of individual words is used to show the interrelations of terms.

coordination—A term describing the ability of the lower rating of two breakers in series to trip before the higher-rating one trips.

copper loss—*See* I^2R Loss.

copper-oxide rectifier — A metallic rectifier in which the rectifying barrier is the junction between metallic copper and cuprous oxide. A disc of copper is coated with cuprous oxide on one side, and a soft lead washer is used to make contact with the oxide layer.



Copper-oxide rectifier.

copper-sulfide rectifier — A semiconductor rectifier in which the rectifying barrier is a junction between magnesium and copper sulfide.

copy—*See* Subject Copy.

copying telegraph—An absolute term for a facsimile system for the transmission of black-and-white copy only.

Corbino effect—A special case of the Hall effect that occurs when a disc carrying a radial current is placed perpendicularly into a magnetic field.

cord—One or a group of flexible insulated conductors covered by a flexible insulation and equipped with terminals.

cord sets—Portable cords fitted with any type of wiring device at one or both ends.

cordwood — A sandwich-type construction wherein components lie in a vertical "cordwood" pattern between horizontal layers.

cordwood module — A high-density circuit module in which discrete components are mounted between and perpendicular to two small, parallel printed-circuit boards to which their terminals are attached.

core—1. A magnetic material placed within a coil to intensify the magnetic field. 2. Magnetic material inside a relay or coil winding.

coreless-type induction heater—A device in which an object is heated by induction without being linked by a magnetic-core material.

core loss—Also called iron loss. Loss of energy in a magnetic core as the result of eddy currents, which circulate through the core and dissipate energy in the form of heat.

core memory — A computer memory device containing magnetic cores.

core plane — A horizontal network of magnetic cores that contains a core common to each storage position.

core storage—In a computer, a form of high-speed storage that uses magnetic cores.

core transformer—A transformer in which the windings are placed on the outside of the core.

core-type induction heater — A device in which an object is heated by induction. Unlike the coreless type, a magnetic core links the inducing winding to the object.

core wrap—Insulation placed over a core before the addition of windings.

corner—An abrupt change in direction of the axis of a waveguide.

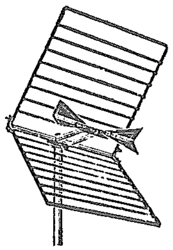
corner cut — A corner removed, for orientation purposes, from a card to be used with a computer.

corner effect—The rounding off of the attenuation versus frequency characteristic of a filter at the extremes (or corners) of the passband.

corner frequency — 1. The frequency at which the open-loop gain-versus-frequency curve changes slope. For a servo motor, the product of the corner frequency in radians per second and the time constant of the motor is unity. 2. The frequency at which the two asymptotes of the gain-magnitude curves of an operational amplifier intersect.

corner reflector—A reflecting object consisting of two (dihedral) or three (trihedral) mutually intersecting conducting surfaces. Trihedral reflectors are often used as radar targets.

corner-reflector antenna—An antenna consisting of a primary radiating element and a dihedral corner reflector formed by the elements of the reflector.



Corner-reflector antenna.

corona—A luminous discharge of electricity, due to ionization of the air, appearing on the surface of a conductor when the potential gradient exceeds a certain value.

corona effect (of alternating current)—The effect produced when two wires, or other conductors having a great difference of voltage, are placed near each other.

corona failure—Failure due to corona degradation at areas of high voltage stress.

corona loss—A loss or discharge which occurs when two electrodes having a great difference of pressure are placed near each other. The corona loss takes place at the critical voltage and increases very rapidly with increasing pressure.

corona resistance—That length of time that an insulation material withstands the action of a specified level of field-intensified ionization that does not result in the immediate, complete breakdown of the insulation. Also called ionization resistance, brush-discharge resistance, or slot-discharge resistance.

corona shield — A shield placed around a high-potential point to redistribute electrostatic lines of force and prevent corona.

corona voltmeter—A voltmeter in which the peak voltage value is indicated by the beginning of corona at a known and calibrated electrode spacing.

corrective equalization—*See* Frequency-Response Equalization.

corrective maintenance—The maintenance performed on a nonscheduled basis to restore equipment to satisfactory condition.

corrective network—Also called shaping network. An electric network designed to be inserted into a circuit to improve its transmission or impedance properties, or both.

correlated characteristic — A characteristic known to be reciprocally related to some other characteristic.

correlation—1. The relationship, expressed as a number between minus one and plus one, between two sets of data, etc. 2. A relationship between two variables; the strength of the linear relationship is indicated by the coefficient of correlation.

correlation detection—A method of detection in which a signal is compared, point to point, with an internally generated reference. The output of such a detector is a measure of the degree of similarity of the input and reference signal. The reference signal is constructed in such a way that it is at all times a prediction, or best guess, of what the input signal should be at that time.

correlation direction finder—A satellite station separated from a radar to receive a jamming signal. By correlating the signals received from several such stations, the range and azimuth of many jammers may be obtained.

correlation distance—A term used in tropospheric propagation. The minimum spatial separation between antennas which will give rise to independent fading of the received signals.

Correlation Orientation Tracking and Range System—A system generally using a parabolic antenna for the analysis of a narrow band of radar energy for tracking and ranging purposes.

correlation tracking and ranging—A nonambiguous short-base-line, single-station c-w phase comparison system measuring two direction cosines and a slant range from which space position can be computed.

correlation tracking and triangulation—A trajectory-measuring system composed of several antenna base lines separated by large distances and used to measure direction cosines to an object. From these measurements, the space position is computed by triangulation.

correlation tracking system—A system utilizing correlation techniques in which signals derived from the same source are correlated to derive the phase difference between the signals. This phase difference contains the system data.

corrosion—A chemical action which causes gradual destruction of the surface of a metal by oxidation or chemical contamination. Also caused by reduction of the electrical efficiency between the metal and a contiguous substance or to the disintegrating effect of strong electrical currents or ground-return currents in electrical systems. The latter is known as electrolytic corrosion.

cosecant - squared antenna — An antenna which emits a cosecant-squared beam. In the shaped-beam antenna used, the radiation intensity over part of its pattern in some specified plane (usually the vertical) is proportionate to the square of the cosecant of the angle measured from a specified direction in that plane (usually the horizontal).

cosecant-squared beam—A radar-beam pattern designed to give uniform signal intensity in echoes from distant and nearby objects. It is generated by a spun-barrel reflector. The beam intensity varies as the square of the cosecant of the elevation angle.

cosine law—The law which states that the brightness in any direction from a perfectly diffusing surface varies in proportion to the cosine of the angle between that direction and the normal to the surface.

cosmic noise—Radio static, the origin of which is due to sources outside the earth's atmosphere. The source may be similar to sunspots, or spots on other stars.

cosmic rays—Any rays of high penetrating power produced by transmutations of atoms in outer space. These particles continually enter the earth's upper atmosphere from interstellar space.

coulomb—The quantity of electricity which passes any point in an electric circuit in 1 second when the current is maintained constant at 1 ampere. The coulomb is the unit of electric charge in the mksa systems.

Coulomb's law—Also called law of electric charges or law of electrostatic attraction. The force of attraction or repulsion between two charges of electricity concentrated at two points in an isotropic medium is proportionate to the product of their magnitudes and is inversely proportionate to the square of the distance between them. The force between unlike charges is an attraction, and between like charges a repulsion.

coulometer—An electrolytic cell which measures a quantity of electricity by the amount of chemical action produced.

Coulter counter—An electronic-cell counting instrument operating on the ion-conductivity principle. Designed by J. R. Coulter. (*Also see* cell counter.)

count — In radiation counters, a single response of the counting system.

countdown—A decreasing tally that indicates the number of operations remaining in a series.

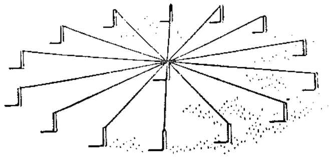
counter—1. A circuit which counts input pulses. One specific type produces one output pulse each time it receives some predetermined number of input pulses. The same term may also be applied to several such circuits connected in cascade to provide digital counting. 2. In mechanical analog computers, a means for measuring the angular displacement of a shaft. 3. Sometimes called accumulator. A device capable of changing from one to the next of a sequence of distinguishable states upon receipt of each discrete input signal.

counter circuit—A circuit which receives uniform pulses representing units to be counted and produces a voltage in proportion to their frequency.

counterclockwise polarized wave—*See* Left-Handed Polarized Wave.

counterelectromotive cell — Cells of practically no ampere-hour capacity used to oppose the line voltage.

counterelectromotive force — Abbreviated counter emf. A voltage developed in an inductive circuit by an alternating or pulsating current. The polarity of this voltage is at every instant opposite that of the applied voltage.



Counterpoise.

counterpoise—A system of wires or other conductors, elevated above and insulated from ground, forming a lower system of conductors of an antenna.

counter tube—Also called radiation counter tube. An electron tube that converts an incident particle or burst of incident radiation into a discrete electric pulse. This is generally done by utilizing the current flow through a gas that is ionized by the radiation.

counting efficiency—In a scintillation counter, the ratio, under specified conditions, of the average number of photons or particles of ionizing radiation that produce counts to the average number of photons or particles incident on the sensitive area.

counting-rate meter—A device for indicating the time rate of occurrence of input pulses averaged over a time interval.

counting-type frequency meter—An instrument for measuring frequency. Its operation depends on the use of pulse-counting techniques to indicate the number and/or rate of recurring electrical signals applied to its input circuits.

counts per turn—The total number of code positions per 360° of encoder shaft rotation.

couple — Two or more dissimilar metals or alloys in electrical contact with each other that act as the electrodes of an electrolytic cell when they are immersed in an electrolyte.

coupled circuit — Any network containing only resistors, inductors (self and mutual), and capacitors, and having more than one independent mesh.

coupler—An arrangement of coils or capacitors so placed with respect to each other that there is electromagnetic or electrostatic coupling between their circuits.

coupling—The association of two or more circuits or systems in such a way that power may be transferred from one to another.

coupling angle—In connection with synchronous motors, the mechanical-degree relationship between the rotor and the rotating field.

coupling aperture—Also called coupling hole or coupling slot. An aperture, in the wall of a waveguide or cavity resonator, designed to transfer energy to or from an external circuit.

coupling capacitor—Any capacitor used to couple two circuits together. Coupling is accomplished by means of the capacitive reactance common to both circuits.

coupling coefficient — Also called coefficient of coupling. The degree of coupling that exists between two circuits. It is equal to the ratio between the mutual impedance and the square root of the product of the total self-impedances of the coupled circuits, all impedances being of the same kind.

coupling hole—*See* Coupling Aperture.

coupling loop—A conducting loop projecting into a waveguide or cavity resonator and designed to transfer energy to or from an external circuit.

coupling probe—A probe projecting into a waveguide or cavity resonator and designed to transfer energy to or from an external circuit.

coupling slot—*See* Coupling Aperture.

coupling transformer—A transformer that couples two circuits together by means of its mutual inductance.

covalent bond—A type of linkage between atoms. Each atom contributes one electron to a shared pair that constitutes an ordinary chemical bond.

coverage—A percentage of the completeness with which a braid or shield covers the surface of underlying insulated conductors or conductor.

cpm—Abbreviation for cycles per minute.

C-power supply—A device connected in the circuit between the cathode and grid of a vacuum tube to apply grid bias.

cps—Abbreviation for cycles per second. Now replaced by hertz (Hz).

crash-locator beacon — Airborne equipment consisting of various transmitters, collapsible antennas, etc., designed to be ejected from a downed aircraft and to transmit beacon signals to help searching forces to locate the crashed aircraft.

crater lamp — 1. A glow-discharge type of vacuum tube the brightness of which is proportional to the current passing through the tube. The glow discharge takes place in a cup or crater rather than on a plate as in a neon lamp. 2. A gaseous lamp usually containing neon. Provides a point source of light that can be modulated with a signal.

crazing—Checking of an insulation material when it is stressed and in contact with certain solvents or their vapors.

creepage — The conduction of electricity across the surface of a dielectric.

creepage distance—The shortest distance between conductors of opposite polarities, or between a live part and ground measured over the surface of the supporting material.

creepage path—The path across the surface of a dielectric between two conductors. Lengthening the creepage path reduces the possibility of arc damage or tracking.

creepage surface—An insulating surface that provides physical separation between two electrical conductors of different potential.

creep recovery—The change in no-load output occurring with time after removal of a load which had been applied for a specific period of time.

crest factor—The ratio of the peak voltage to the rms voltage of a waveform (with the d-c component removed.)

crest factor of a pulse—The ratio of the peak amplitude to the rms amplitude of a pulse.

crest value—Also called peak value. The maximum absolute value of a function.

crest voltmeter—A peak-reading voltmeter.

crimp — To compress or deform a connector barrel around a cable so as to make an electrical connection.

crimp contact—A contact whose back portion is a hollow cylinder to allow it to accept a wire. After a bared wire is inserted, a swedging tool is applied to crimp the contact metal firmly against the wire. An excellent mechanical and electrical contact results. A crimp contact often is referred to as a solderless contact.

crippled leapfrog test—In a computer, a variation of the "leapfrog" test in which the test is repeated from a single set of storage locations rather than from a changing set of storage locations.

critical angle—The maximum angle at which a radio wave may be emitted from an antenna and still be returned to the earth by refraction in the ionosphere.

critical area—*See* elemental area.

critical characteristic—A characteristic not having the normal tolerance to variables.

critical coupling—Also called optimum coupling. Between two circuits independently resonant to the same frequency, the degree of coupling which transfers the maximum amount of energy at the resonant frequency.

critical current—That current, at a specified temperature and in the absence of external magnetic fields, above which a material is normal and below which it is superconducting.

critical damping—1. The value of damping which provides the most rapid transient response without overshoot. 2. Operation on the borderline between underdamping and overdamping.

critical dimension — The dimension of a waveguide cross section that determines the cutoff frequency.

critical failure—A failure that causes a system to operate outside designated limits.

critical field—Also called cutoff field. Of a magnetron, the smallest theoretical value of a steady magnetic-flux density, at a steady anode voltage, that would prevent an electron emitted from the cathode at zero velocity from reaching the anode.

critical frequency—Also called penetrating frequency. The limiting frequency below which a magneto-ionic wave component is reflected by an ionospheric layer and above which the component penetrates the layer at vertical incidence. (*Also see* Waveguide Cutoff Frequency.)

critical grid current—The instantaneous value of grid current in a gas tube when the anode current starts to flow.

critical grid voltage — The instantaneous value of grid voltage at which the anode current starts to flow in a gas tube.

critical high-power level—The radio-frequency power level at which ionization is produced in the absence of a control-electrode discharge.

critical item—*See* Critical Part.

critical magnetic field — That field intensity below which at a specified temperature and in the absence of current, a material is superconducting and above which it is normal.

critical part—A part whose failure to meet specified requirements results in the failure of the product to serve its intended purpose. Also called critical item.

critical potential—*See* Ionization Potential.

critical temperature—That temperature below which, in the absence of current and external magnetic fields, a material is superconducting and above which it is normal.

critical voltage—Also called cutoff voltage. In a magnetron, the highest theoretical value of steady anode voltage, at a given steady magnetic-flux density, at which electrons emitted from the cathode at zero velocity will fail to reach the anode.

critical wavelength — The free-space wavelength corresponding to the critical frequency.

cro — Abbreviation for cathode-ray oscilloscope.

Crookes dark space — *See* Cathode Dark Space.

Crosby system—A compatible multiplex f-m stereo broadcast technique in which the right and left signals are combined in phase (sum signal) and transmitted on the main carrier, and also combined out-of-phase (difference signal) and transmitted on the subcarrier. The two signals are combined (matrixed) in the receiving apparatus to restore the right and left channels.

crossbanding—The use of combinations of interrogation and reply frequencies such that either one interrogation frequency is used with several reply frequencies or one reply frequency is used with several interrogation frequencies.

crosscheck—To check a computation by two different methods.

cross color — The interference in a color-television receiver chrominance channel caused by cross talk from monochrome signals.

cross coupling—Unwanted coupling between two different communication channels or their components.

crossed-field amplifier—A high-power electron tube in which direct-current power is converted to microwave power by a combination of crossed electric and magnetic fields.

crossed-pointer indicator — A two-pointer indicator used with instrument landing systems to indicate the position of an aircraft with respect to the glide path.

crossfire — Interfering current in one telegraph or signaling channel resulting from telegraph or signaling currents in another channel.

crossfoot—1. In a computer, to add or subtract numbers in different fields of the same punch card and punch the result into another field of the same card. 2. To compare totals of the same numbers obtained by different methods.

cross-hatching — In a printed-circuit board, the breaking up of large conductive areas where shielding is required.

cross magnetostriction — Under specified conditions, the relative change of dimension in a specified direction perpendicular to the magnetization of a body of ferromagnetic material when the magnetization of the body is increased from zero to a specified value (usually saturation).

cross modulation—A type of intermodulation that occurs when the carrier of the desired signal is modulated by an undesired signal.

cross neutralization—A method of neutralization used in push-pull amplifiers. A portion of the plate-to-cathode a-c voltage of each tube is applied to the grid-to-cathode circuit of the other tube through a neutralizing capacitor.

crossover—The point where two conductors that are insulated from each other cross.

crossover distortion—Distortion that occurs in a push-pull amplifier at the points of operation where the input signals cross over (go through) the zero reference points.

crossover frequency—As applied to electrical dividing networks, the frequency at which equal power is delivered to each of the adjacent-frequency channels when all channels are terminated in the specified load. (*Also see* Transition Frequency.)

crossover network — A selective network which divides its audio input into two or more frequency bands for distribution to speakers.

crossover spiral—*See* Leadover Groove.

cross polarization—The component electric field vector normal to the desired polarization component.

cross-sectional area of a conductor—The summation of all cross-sectional areas of the individual strands in the conductor, expressed in square inches or more commonly in circular mils.

cross talk—Interference which appears in a given transmitting or recording channel but has its origin in another channel. (*Also see* Magnetic Printing.)

cross-talk coupling — Also called cross-talk loss. Cross coupling between speech communication channels or their component parts. Note: Cross-talk coupling is measured between specified points of the disturbing and disturbed circuit and is preferably expressed in decibels.

cross-talk level — The volume of cross-talk energy, measured in decibels, referred to a base.

cross-talk loss—*See* Cross-talk Coupling.

crowbar—A term describing the action which effectively creates a high overload on the actuating member of the protective device. This crowbar action may be triggered by a slight increase in current or voltage.

crowbar voltage protector—A separate circuit which monitors the output of a power supply and instantaneously throws a short circuit (or crowbar) across the output terminals of the power supply whenever a preset voltage limit is exceeded. An scr is usually used as the crowbar device.

crt—Abbreviation for cathode-ray tube.

cryogenic device—A device intended to function best at temperatures near absolute zero.

cryogenic motor—A motor that operates at a temperature below −129°C and that uses a cryogenic fluid or gas to cool its windings and bearings.

cryogenics—The study and use of devices utilizing properties of materials near absolute zero in temperature.

cryosar—A semiconductor device primarily intended for high-speed computer switching and memory applications. This device operates by the low-temperature avalanche breakdown produced by impact ionization of impurities.

cryostat—A refrigerating unit such as that for producing or utilizing liquid helium in establishing extremely low temperatures (approaching absolute zero).

cryotron — A superconductive four-terminal device in which a magnetic field, produced by passing a current through two input terminals, controls the superconducting-to-

normal transition—and thus the resistance—between the two output terminals.

cryotronics — A contraction of "cryogenic electronics."

crystal—A solid in which the constituent atoms are arranged with some degree of geometric regularity. In communication practice, a piezoelectric crystal, piezoelectric crystal plate, or crystal rectifier.

crystal anisotropy — A force which directs the magnetization of a single-domain particle along a direction of easy magnetization. To rotate the magnetization of the particle, an applied magnetic field must provide enough energy to rotate the magnetization through a difficult crystal direction.

crystal audio receiver—Similar to the crystal video receiver except for the path detection bandwidth, which is audio rather than video.

crystal calibrator—A crystal-controlled oscillator used as a reference to check and set the frequency tuning of a receiver or transmitter.

crystal can relay—A relay mounted in a can of a specific size and shape; called a crystal can because of its common usage as a mounting for quartz crystals used in frequency-control circuits.

crystal control—Control of the frequency of an oscillator by means of a specially designed and cut crystal.

crystal-controlled oscillator — *See* Crystal Oscillator.

crystal-controlled transmitter — A radio transmitter in which the carrier frequency is controlled directly by a crystal oscillator.

crystal cutter—A disc cutter in which the mechanical displacements of the recording stylus are derived from the deformities of a crystal having piezoelectric properties.

crystal detector—A mineral or crystalline material which allows electrical current to flow more easily in one direction than in the other. In this way, an alternating current can be converted to a pulsating current.

crystal diode—A rectifying element comprising a semiconductor crystal having two terminals. Its operation is analogous to that of electron-tube diodes.

crystal filter—A highly selective circuit capable of discriminating against all signals except those at the center frequency of a crystal, which serves as the selective element.

crystal headphones—Headphones using Rochelle-salt or other crystal elements to convert audio-frequency signals into sound waves.

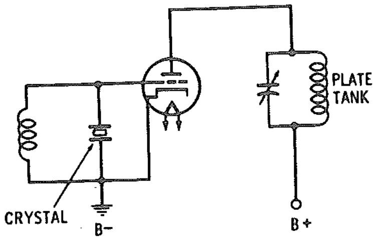
crystal holder—A case of insulating material for mounting a crystal. External prongs allow the crystal to be plugged into a suitable socket.

crystal imperfection—Any deviation in lattice structure from that of a perfect single crystal.

crystal microphone—Also called piezoelectric microphone. A microphone which depends for its operation on the generation of an electric charge by the deformation of a body (usually crystalline) having piezoelectric properties.

crystal mixer—1. A mixer circuit with the frequency of the local oscillator being controlled by a crystal. Normally used in superheterodyne radio receivers. 2. A mixer that utilizes the nonlinear characteristic of a crystal diode to mix two frequencies. Frequently used in radar receivers to convert the received radar signal to a lower i-f signal by mixing it with a local-oscillator signal.

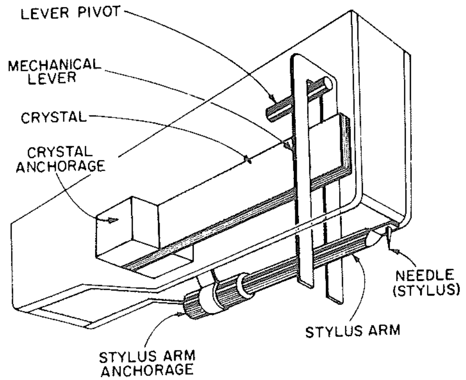
crystal operation—Operation using crystal-controlled oscillators.



Crystal oscillator.

crystal oscillator — Also called crystal-controlled oscillator. An oscillator in which the frequency of oscillation is controlled by a piezoelectric crystal.

crystal oven—A container, maintained at a constant temperature, in which a crystal and its holder are enclosed in order to keep their temperature constant and thereby reduce frequency drift.



Crystal pickup.

crystal pickup — Also called piezoelectric pickup. A phonograph pickup which depends for its operation on the generation of an electric charge by the deformation of a body (usually crystalline) having piezoelectric properties.

crystal pulling—A method of growing crystals in which the developing crystal is gradually withdrawn from a melt.

crystal rectifier—An electrically conductive or semiconductive substance, natural or synethetic, which has the property of rectifying small radio-frequency voltages.

crystal set—A simple type of radio receiver having only a crystal-detector stage for demodulation of the received signal and no amplifier stages.

crystal slab—A relatively thick piece of crystal from which crystal blanks are then cut.

crystal speaker—Also called piezoelectric speaker. A speaker in which the mechanical displacements are produced by piezoelectric action.

crystal-stabilized transmitter—A transmitter employing automatic frequency control, in which the reference frequency is the same as the crystal-oscillator frequency.

crystal transducer—*See* Piezoelectric Transducer.

crystal video receiver—A radar receiver consisting only of a crystal detector and video amplifier.

C-scope—A rectangular radar display in which targets appear as bright spots with azimuth indicated by the horizontal coordinate and elevation angle by the vertical coordinate.

CT-cut crystal—A natural quartz crystal cut to vibrate below 500 kHz.

CTL—Abbreviation for complementary transistor logic.

cubical antenna—An antenna array, the elements of which are positioned to form a cube.

cue circuit—A one-way communication circuit for conveying program control information.

cup—A single mechanical section of a potentiometer which may contain one or more electrical resistance elements.

cup core—A core which forms a magnetic shield around an inductor. Usually a cylinder with one end closed. A center core inside the inductor is normally used and may or may not be part of the cup core.

cup washer—A washer formed with a recess in one side to retain compression springs or, on binding-post terminals, to prevent escape of connecting wire strands.

curie—A unit used for indicating the strength of radioactive sources in terms of the number of disintegrations per second in the source. One curie is equal to 3.7 × 10^{10} disintegrations per second.

Curie point—Also called magnetic transition temperature. The temperature above which a ferromagnetic material becomes substantially nonmagnetic.

curing temperature—Temperature at which a material undergoes a curing process.

Curpistor—A subminiature constant-current tube containing two electrodes and filled with radioactive nitrogen.

current—The movement of electrons through a conductor. Measured in amperes, and its symbol is I.

current amplification—1. The ratio of the current produced in the output circuit of an amplifier to the current supplied to the input circuit. 2. In photomultipliers, the ratio of the signal output current to the photoelectric signal current from the photocathode.

current amplifier—A device designed to deliver a greater output current than its input current.

current antinode—Also called current loop. The point at which current is a maximum along a transmission-line antenna or other circuit element having standing waves.

current attenuation—The ratio of the magnitude of the current in the input circuit of a transducer to the magnitude of the current in a specified load impedance connected to the transducer.

current-balance relay—A relay in which operation occurs when the magnitude of one current exceeds the magnitude of another current by a predetermined ratio.

current-carrying capacity—The maximum current a conductor (or braid) can carry without heating beyond a safe limit.

current-carrying rating—The current that can be carried continuously or for stated periodic intervals without impairment of the contact structure or interrupting capability.

current density—The amount of electric current passing through a given cross-sectional area of a conductor in amperes per square inch—i.e., the ratio of the current in amperes to the cross-sectional area of the conductor.

current echo—The signal which on a transmission line is reflected as the result of some discontinuity.

current feed—A method of feeding to a point where the current is a maximum (e.g., at the center of a half-wave antenna).

current flicker—Current surges resulting from momentary shorts that can occur within a solid-electrolytic capacitor. They may produce a leakage-current increase, a decrease, no change at all, or a catastrophic failure. Under certain conditions, current flicker can avalanche to cause a short, which under low-impedance circuit conditions results in catastrophic destruction of the capacitor.

current generator—A two-terminal circuit element with a terminal current independent of the voltage between its terminals.

current limiting (automatic)—An overload-protection mechanism which limits the maximum output current of a power supply to a preset value and automatically restores the output when the overload is removed. (*Also see* Short-Circuit Protection.)

current-limiting fuse—A protective device which anticipates a dangerous short-circuit current and opens the circuit, precluding the development of the peak available current.

current-limiting reactor—A form of reactor intended for limiting the current that can flow in a circuit under short-circuit conditions.

current-limiting resistor—A resistor inserted into an electric circuit to limit the flow of current to some predetermined value. Usually inserted in series with a fuse or circuit breaker to limit the current flow during a short circuit or other fault, to prevent excessive current from damaging other parts of the circuit.

current loop—*See* Current Antinode.

current margin—The difference between the steady-state currents flowing through a telegraph receiving instrument corresponding, respectively, to the two positions of the telegraph transmitter.

current-mode logic—Abbreviated CML. A nonsaturating logic circuit that employs the characteristics of a differential amplifier circuit in its design. Because it is nonsaturating, it is the fastest switching logic design. The gate input element is the base of a transistor with a separate transistor for each input.

current node—A point at which current is zero along a transmission line, antenna, or any other circuit element that has standing waves.

current noise—Also called excess noise. A low-frequency noise caused by current flowing in a resistor, particularly a carbon resistor. The amount varies widely with the type and construction of the resistor. This low-frequency noise is generally measurable only in the region below 100 kHz, and the noise power varies inversely with frequency.

current probe—A type of transformer usually having a snap-around configuration, used for measuring the current in a conductor.

current pump—A circuit that drives, through an external load circuit, an adjustable variable or constant value of current, regardless of the reaction of that load to the current, within rated limits of current, voltage, and load impedance.

current regulator—A device that functions to maintain the output current of a generator or other voltage source at a predetermined value, or varies the voltage according to a predetermined plan.

current relay—A relay that operates at a predetermined value of current. It can be an overcurrent relay, an undercurrent relay, or a combination of both.

current saturation—The condition in which the plate current of a vacuum tube cannot be further increased by increasing the plate voltage.

current-sensing resistor—A resistor of low value placed in series with the load to develop a voltage proportional to the output current. A regulated d-c power supply regulates the current in the load by regulating the voltage across this sensing resistor.

current sensitivity—The current required to give standard deflection on a galvanometer.

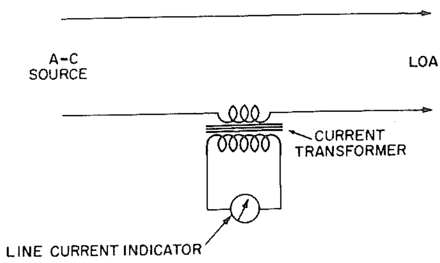
current-sinking logic—Also called input-coupled logic. A logic form that requires that current flow out of the input of a circuit and back into the output of the preceding stage, which serves as a current sink instead of a source.

current-sourcing logic—Also called collector-coupled logic. A logic form where current flows from the output of a circuit and is forced into the input of a similar circuit to activate the circuit which drives.

current-stability factor—In a transistor, the ratio of a change in emitter current to a change in reverse-bias current between the collector and base.

current-transfer ratio—*See* Beta.

current transformer—A transformer, intended for measuring or control purposes, designed to have its primary winding connected in series with a circuit carrying the current to be measured or controlled.



Current transformer.

current-type telemeter—A telemeter in which the magnitude of a single current is the translating means.

cursor—1. A mechanically or electronically generated line which moves back and forth over another surface to delineate accurate readings. 2. A mechanical bearing line on a plan position indicator-type display for reading target bearing.

customer set—*See* Subscriber Set.

Cutler feed—A resonant cavity, at the end of a waveguide, which feeds radio-frequency energy to the reflector of the antenna assembly of some airborne antennas.

cutoff—1. Minimum value of bias which cuts off, or stops, the flow of plate current in a tube. 2. The frequency above or below which a selective circuit fails to respond. 3. The frequency of transmission at which the loss exceeds by 10 decibels that observed at 1,000 hertz.

cutoff attenuator—A variable length of waveguide used below the cutoff frequency of the waveguide to introduce variable nondissipative attenuation.

cutoff current—Transistor collector current with no emitter current and normal collector-to-base bias.

cutoff field—*See* Critical Field.

cutoff frequency—The frequency at which the gain of an amplifier falls below .707 times the maximum gain.

cutoff frequency of a line—The upper frequency limit, usually of a loaded transmission circuit, beyond which the attenuation rises very rapidly.

cutoff limiting—Keeping the output of a vacuum tube below a certain point by driving the control grid beyond cutoff.

cutoff voltage—1. The electrode voltage which reduces the dependent variable of an electron-tube characteristic to a specified value. (*Also see* Critical Voltage.) 2. The voltage at which the discharge is considered complete. This need not be a very low voltage.

cutoff wavelength—The ratio of the velocity of electromagnetic waves in free space to the cutoff frequency of a waveguide.

cutout—1. An electrical device that interrupts the flow of current through any particular apparatus or instrument, either automatically or manually. 2. Pairs brought out of a cable and terminated at some place other than at the end of the cable.

cut-signal branch operation — In systems where radio reception continues without cutting off the carrier, the cut-signal branch operation technique disables a signal branch in one direction when it is enabled in the other to preclude unwanted signal reflections.

cutter — Also called mechanical recording head. An electromechanical transducer which transforms an electric input into a mechanical output (for example, the mechanical motions which a cutting stylus inscribes into a recording medium).

cut-through—The resistance of a solid material to penetration by an object under conditions of pressure, temperature, etc.

cut-through flow test—A test to measure the resistance to deformation of insulation subjected to heat and pressure.

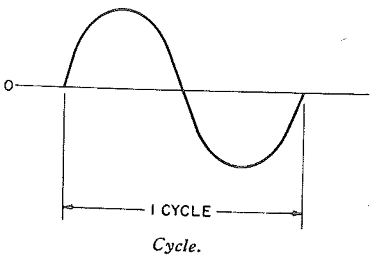
cutting rate—The number of lines per inch the lead screw moves the cutting-head carriage across the face of a recording blank. Standard rates are 96, 104, 112, 128, 136, and greater in multiples of eight lines per inch. For microgroove recordings, 200 to 300 lines per inch are used.

cw—Abbreviation for: 1. Continuous wave. 2. Clockwise.

c-w reference signal—In color television, a sinusoidal signal used to control the conduction time of a synchronous demodulator.

cybernetics—The study of systems of control and communications in humans and animals, and in electrically operated devices such as calculating machines.

cycle—1. The change of an alternating wave from zero to a negative peak to zero to a positive peak and back to zero. The number of cycles per second (hertz) is called the frequency. (*Also see* Alternation.) 2. An off-on application of power.



Cycle.

cycle counter—A mechanism or device used to record the number of times a specified cycle is repeated.

cycle index—1. In digital computer programming, the number of times a cycle has been executed. 2. The difference between the number of times a cycle has been executed and the number of times it is desired that the cycle be repeated.

cycle life—For rechargeable cells, the total number of discharge/charge cycles before the cell becomes inoperative.

cycle reset—To return a cycle index to its initial value.

cycle shift — In a computer, the removal of the digits of a number or characters from a word from one end of the number or word and their insertion, in the same sequence, at the other end.

cycle timer—A controlling mechanism which opens or closes contacts according to a preset cycle.

cyclically magnetized condition—The condition of a magnetic material after being under the influence of a magnetizing force varying between two specific limits until, for each increasing (or decreasing) value of the magnetizing force, the magnetic-flux density has the same value in successive cycles.

cyclic code—Positional notation, not necessarily binary, in which quantities differing by one unit are represented by expressions which are identical except for one place or column, and the digits in that place or column differ by only one unit. Cyclic codes are often used in mechanical devices because no ambiguity exists at the changeover point between adjacent quantities.

cyclic memory—A memory that continuously stores information but provides access to any piece of stored information only at multiples of a fixed time called the cycle time.

cyclic shift—A shift in which the data moved out of one end of the storing register are reentered into the other end, as in a closed loop.

cycling vibration—Sinusoidal vibration applied to an instrument and varied in such a way that the instrument is subjected to a specified range of vibrational frequencies.

cycloconverter—A step-down static frequency converter that produces a constant or a precisely controllable output frequency from a variable-frequency a-c power input. In general, the frequency ratio chosen is three to one, or greater.

cyclogram—An oscilloscope display obtained by monitoring two voltages having a direct cyclic relationship to each other.

cycloidotron—A fast-wave crossed-field microwave tube similar to the cyclotron resonance tube.

cyclometer register—A set of four or five wheels numbered from 0 to 9 inclusive on their edges, and enclosed and connected by gearing so that the register reading appears as a series of adjacent digits.

cyclotron—A device consisting of an evacuated tank in which positively charged particles (for example, protons, deuterons, etc.) are guided in spiral paths by a static magnetic field while being highly accelerated by a fixed-frequency electric field.

cyclotron frequency — The frequency at which an electron traverses an orbit in a steady, uniform magnetic field and zero electric field. Given by the product of the electronic charge and the magnetic-flux density, divided by 2π times the electron mass.

cyclotron-frequency magnetron oscillations—Those oscillations having substantially the same frequency as that of the cyclotron.

cyclotron radiation — The electromagnetic radiation emitted by charged particles orbiting in a magnetic field. It arises from the centripetal acceleration of the particle moving in a circular orbit.

cyclotron resonance—The effect characterized by the tendency of charge carriers to spiral around an axis in the same direction as an applied magnetic field, with an angular frequency determined by the value of the applied field and the ratio of the charge to the effective mass of the charge carrier.

cylindrical reflector—A reflector which is part of a cylinder, usually parabolic.

cylindrical wave—A wave the equiphase surfaces of which form a family of coaxial cylinders.

Czochralski technique—A method of growing large single crystals by pulling them from a molten state. Usually used for growing single crystals of germanium and silicon.

D

D—Symbol for electrostatic flux density, deuterium, or dissipation factor.

dag—Abbreviation for Aquadag.

Damon effect—The change in susceptibility of a ferrite, caused by a high r-f power input.

damped natural frequency—1. The frequency at which a system with a single degree of freedom will oscillate, in the presence of damping, after momentary displacement from the rest position by a transient force. 2. The rate of free oscillation of a sensing element in the presence of damping.

damped oscillation—The oscillation that occurs when the amplitude of the oscillating quantity decreases with time. If the rate of decrease can be expressed mathematically, the name of the function describes the damping. Thus, if the rate of decrease is expressed as a negative exponential, the system is said to be an exponentially damped system.

damped waves—Waves in which successive cycles at the source progressively diminish in amplitude.

dampen—1. To diminish progressively in amplitude; usually said of waves or oscillations. 2. To deaden vibrations.

damper—*See* Stabilizer.

damper tube—The tube which conducts in the horizontal-output circuit of a television receiver when the current in the horizontal-deflecting yoke reaches its negative peak. This causes the sawtooth deflection current to decrease smoothly to zero instead of continuing to oscillate.

damper winding—In electric motors, a permanently short-circuited winding, usually uninsulated, and arranged so that it opposes rotation or pulsation of the magnetic field with respect to the pole shoes.

damping—1. Reduction of energy in a mechanical or electrical system by absorption or radiation. 2. Act of reducing the amplitude of the oscillations of an oscillatory system, hindering or preventing oscillation or vibration, or diminishing the sharpness of resonance of the natural frequency of a system. 3. The dissipation of kinetic energy in a system by a controlled energy-absorbing medium. A system can be described as being either critically damped, overdamped, or underdamped. 4. The manner in which the pointer settles to its steady indication after a change in the value of the measured quantity. Two general classes of damped motion are: a. Periodic, in which the pointer oscillates about the final position before coming to rest; b. Aperiodic, in which the pointer comes to rest without overshooting the rest position. Sometimes referred to as overdamping.

damping coefficient—The ratio of actual damping to critical damping.

damping constant—The Napierian logarithm of the ratio of the first to the second of two values of an exponentially decreasing quantity separated by a unit of time.

damping diode — A vacuum tube which damps the positive or negative half-cycle of an a-c voltage.

damping factor — 1. For any underdamped motion during any complete oscillation, the quotient obtained by dividing the logarithmic decrement by the time required by the oscillation. 2. Numerical quantity indicating ability of an amplifier to operate a speaker properly. Values over 4 are usually considered satisfactory. 2. The ratio of rated load impedance to the internal impedance of an amplifier. 3. *See* Decrement.

damping magnet—A permanent magnet and a movable conductor such as a sector or disc arranged in such a way that a torque (or force) is produced which tends to oppose any relative motion.

damping of an instrument—The manner in which the pointer of an instrument settles to a steady indication after a change in the measured quantity has occurred.

damping ratio—1. The ratio of the degree of actual damping to the degree of damping required for critical damping. May be effected by changes in ambient temperature. 2. Of a galvanometer, the ratio, expressed as a positive number, of a given deflection to the next deflection in the opposite direction. The greater this ratio, the greater the degree of damping. The natural logarithm of this ratio is called the logarithmic decrement.

Daniell cell—A cell having a copper electrode in a copper-sulfate solution and a zinc electrode in a diluted sulfuric acid or zinc-sulfate solution, with the two solutions separated by a porous partition. Generates an essentially constant electromotive force of about 1.1 volts.

daraf—The unit of elastance. It equals the reciprocal of capacitance and is actually farad spelled backward.

dark conduction—Residual electrical conduction in a photosensitive substance in total darkness.

dark current—*See* Electrode Dark Current.

dark discharge—In a gas, an electric discharge that has no luminosity.

dark-field disc—A disc used in the optical-electronic type of cell counter that controls light transmission.

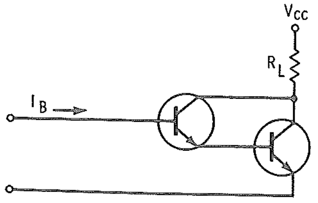
dark resistance—The resistance of a photoelectric device in total darkness.

dark spot—A phenomenon sometimes observed in a reproduced television image. It is caused by the formation of electron clouds in front of the mosaic screen in the transmitter camera tube.

dark spot signal—The signal existing in a television system while the television camera is scanning a dark spot.

dark-trace tube—A cathode-ray tube with a screen coated with a halide of sodium or potassium. The screen normally is nearly white, and whenever the electron beam strikes, it turns a magenta color which is of long persistence. The screen can be illuminated by a strong light source, so that the reflected image may be made intense enough to be projected.

Darlington amplifier—Also called Darlington pair, double-emitter follower, or B multiplier. A transistor circuit which, in its original form, consists of two transistors in which the collectors are tied together and the emitter of the first transistor is directly coupled to the base of the second transistor. Therefore, the emitter current of the first transistor equals the base current of the second transistor. This connection of two transistors can be regarded as a compound transistor with three terminals.



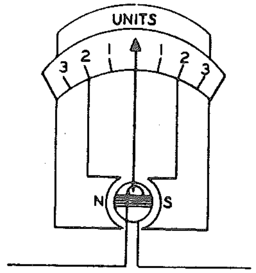
Darlington amplifier.

Darlington pair—*See* Darlington Amplifier.

D'Arsonval current—A high-frequency, low-voltage current of comparatively high amperage.

D'Arsonval galvanometer—A d-c galvanometer consisting of a narrow rectangular coil suspended between the poles of a permanent magnet.

D'Arsonval instrument—*See* Permanent-Magnet Moving-Coil Instrument.



D'Arsonval movement.

D'Arsonval movement—A meter movement consisting essentially of a small, lightweight coil of wire supported on jeweled bearings between the poles of a permanent magnet. When the direct current to be measured is sent through the coil, its magnetic field interacts with that of the permanent magnet and causes the coil and attached pointer to rotate.

dash—Term used in radiotelegraphy. It consists of three units of a sustained transmitted signal followed by one unit during which no signal is transmitted.

dashpot—A device using a gas or liquid to absorb energy from or retard the movement of the moving parts of a circuit breaker or other electrical or mechanical device.

data—A general term used to denote any or all facts, numbers, letters, and symbols, or facts that refer to or describe an object, idea, condition, situation, or other factors. It connotes basic elements of information which can be processed or produced by a computer. Sometimes data are considered to be expressible only in numerical form, but information is not so limited.

data acquisition system—A system in which a computer at a central computing facility gathers data from multiple remote locations.

data collection—In a computer, the transferring of data from one or more points to a central point. Also called data gathering.

data communication—The transmission of information from one point to another.

data conversion—The changing of data from one form of representation to another.

data element—An element which converts data functions into a usable signal. (*Also see* Element.)

data-flow diagram—An illustration having a configuration such that it suggests a certain amount of circuit operation.

data gathering—*See* Data Collection.

data-handling capacity—The number of bits of information which may be stored in a computer system at one time. The rate at which these bits may be fed to the input either by hand or with automatic equipment.

data-handling system—Semiautomatic or automatic equipment used in the collection, transmission, reception, and storage of numerical data.

data link—Electronic equipment which permits automatic transmission of information in digital form.

data processing—The handling of information in a sequence of reasonable operations.

data-processing machines—A general name for a machine which can store and process numerical and alphabetical information.

data processor—An electronic or mechanical machine for handling information in a sequence of reasonable operations.

data reduction—The process of summarizing a large quantity of experimentally obtained data.

dataset—A circuit termination device used to provide interface between a circuit and terminal input/output equipment.

data synchronizer—A device that controls and synchronizes the transmission of data between an input/output (I/O) device and the computer system.

data transmission—The sending of information from one place to another or from one part of a system to another.

data-transmission equipment—The communications equipment used in direct support of data-processing equipment.

data transmission utilization measure—In a data-transmission system, the ratio of the useful data output to the total data input.

daylight visible range—The maximum range at which, under given conditions, a large black object can be seen against a white sky.

db—Abbreviation for decibel.

dba—Abbreviation for decibels adjusted. Used in conjunction with noise measurements. The reference level is −90 dbm, and the adjustment depends on the frequency-band weighting characteristics of the measuring device.

dbj—A unit used to express relative r-f signal levels. The reference level is zero dbj = 1,000 microvolts. (Originated by Jerrold Electronics.)

dbk—Decibels referred to 1 kilowatt.

dbm—Abbreviation for decibels above (or below) one milliwatt. A quantity of power expressed in terms of its ratio to 1 milliwatt.

db meter—A meter having a scale calibrated to read directly in decibel values at a specified reference level (usually one milliwatt equals zero db).

dbRAP—Decibels above reference acoustical power, which is defined as 10^{-16} watts.

dbRN—Decibels above reference noise. This is a unit used to show the relationship between the interfering effect of a noise frequency, or band of noise frequencies, and a fixed amount of noise power commonly called reference noise. A tone of 1000 hertz having a power level of −90 dbm was selected as the reference noise power because it appeared to have negligible interfering effect and would permit the measurement of interfering effect in positive numbers.

dbv—The increase or decrease in voltage independent of impedance levels.

dbw—Decibels referred to 1 watt.

dbx—Decibels above the reference coupling. Reference coupling is defined as the coupling between two circuits that would be required to give a reading of 0 dba on a two-type noise-measuring set connected to the disturbed circuit when a test tone of 90 dba (using the same weighting as that used on the disturbed circuit) is impressed on the disturbing circuit.

dc—Abbreviation for direct current.

D cable—Two-conductor cable, each conductor having the shape of the capital letter D, with insulation between the conductors and between the conductors and the sheath.

d-c amplifier—*See* Direct-Current Amplifier.

d-c balance—An adjustment of circuitry to avoid a change in d-c level when the gain is changed.

d-c beta—The d-c current gain of a transistor; the ratio of the collector current to the base current that caused it, measured at constant collector-to-emitter voltage.

d-c block—A coaxial component employed to prevent the flow of d-c or video along a transmission line while allowing the uninterrupted flow of r-f. The structure is of a short section of coaxial line, having a capacitance in series with the center and/or outer conductor. The r-f flows with negligible reflection or attenuation, while the video frequencies or d-c are blocked.

dcc—Abbreviation for double cotton-covered.

d-c circuit breaker—A device used to close and interrupt a d-c power circuit under normal conditions or to interrupt this circuit under fault or emergency conditions.

d-c component—The average value of a signal. In television it represents the average luminance of the picture being transmitted, and in radar it is the level from which the transmitted and the received pulses rise.

d-c coupled—The connection by a device which passes the steady-state characteristics of a signal and which largely eliminates the transient or oscillating characteristics of the signal.

d-c dump—The withdrawal of direct-current power from a computer. This may result in loss of the stored information.

d-c generator—A rotating electric device for converting mechanical power into d-c power.

d-c inserter stage—A television transmitter stage that adds a d-c component known as the pedestal level to the video signal.

d-c leakage current—The conduction current that flows through a capacitor when rated d-c voltage is applied.

d-c noise—The noise arising when reproducing a tape which has been nonuniformly magnetized by energizing the record head with direct current, either in the presence or absence of bias. This noise has pronounced long-wavelength components which can be as much as 20 db higher than those obtained from a bulk-erased tape.

d-c noise margin—The difference between the output voltage level of a driving gate and the input threshold voltage of a driven gate for both the "1" and the "0" states.

d-c operating point—The d-c values of collector voltage and current of a transistor with no signal applied.

d-c overcurrent relay—A device which functions when the current in a d-c circuit exceeds a given value.

d-c patch bay — Specific patch panels provided for termination of all direct-current circuits and equipment used in an installation.

d-c picture transmission—Transmission of the d-c component of the television picture signal. This component represents the background or average illumination of the over-all scene and varies only with the over-all illumination.

d-c plate resistance—The value or characteristic used in vacuum-tube computations. It is equal to the direct-current plate voltage divided by the direct-current plate current and is given the symbol r_p.

d-c reclosing relay—A device which controls the automatic closing and reclosing of a d-c circuit interrupter, generally in response to load-circuit conditions.

d-c resistivity—The resistance of a body of ferromagnetic material having a constant cross-sectional area, measured under stated conditions by means of direct voltage, multiplied by the cross-sectional area, and divided by the length of the body.

d-c restoration—The re-establishment, by a sampling process, of the d-c and the low-frequency component which, in a video signal, have been suppressed by a-c transmission.

d-c restorer—Also called clamper or restorer. A clamping circuit which holds either amplitude extreme of a signal waveform to a given reference level of potential.

d-c shift — An error in transient response, with a time constant approaching several seconds.

d-c short—A coaxial component that provides a d-c circuit between the center and outer conductors, while allowing the r-f signal to flow uninterrupted. The unit has a high-impedance line shunted across the main coax line. This consequently makes this device frequency dependent. However, it can be acquired in octave bandwidths.

d-c signaling—A transmission method which utilizes direct current.

DCTL — Abbreviation for direct-coupled transistor logic.

d-c transducer—A transducer capable of proper operation when excited with direct current. Its output is given in terms of direct current unless otherwise modified by the function of the stimulus.

d-c transmission—Transmission of a television signal in such a way that the d-c component of the picture signal is still present. This is done to maintain the true level of background illumination.

dcwv—Abbreviation for direct current working volts. The maximum continuous voltage which can be applied to a capacitor.

deac—A device employed in frequency-modulation receivers to de-emphasize the higher frequencies in the received signal so as to restore their proper relative amplitude. (*Also see* De-emphasis.)

deaccentuator — A network or circuit employed in frequency-modulated receivers to de-emphasize the higher frequencies in the received signal to store their proper relative amplitude.

dead—Free from any electric connection to a source of potential difference and from electric charge; having the same potential as that of earth. The term refers only to current-carrying parts which are sometimes alive, or charged.

dead band—1. In a control system, the range of values through which the measurand can be varied without initiating an effective response. 2. Also called dead space, dead zone, or switching blank. A specified range of values in which the incoming signal can be altered without also changing the outgoing response.

deadbeat—Coming to rest without vibration or oscillation — i.e., the pointer which a highly damped meter or galvanometer moves to a new position without overshooting and vibrating about its final position.

deadbeat instrument—A voltmeter, ammeter, or similar device in which the movement is highly damped to bring it to rest quickly.

dead break—An unreliable contact made near the trip point of a relay or switch at low contact pressure. As a result, the switch does not actuate, even though the circuit is interrupted.

dead end—1. In a sound studio, the end with the greater sound-absorbing characteristic. 2. In a tapped coil, the portion through which no current is flowing at a particular bandswitch position.

dead-end tower—An antenna or transmission-line tower designed to withstand unbalanced mechanical pull from all the conductors in one direction, together with the wind strain and vertical loads.

dead room—A room for testing the acoustic efficiency or range of electroacoustic devices such as speakers and microphones. The room is designed with an absolute minimum of sound reflection, and no two dimensions of the room are the same. A ratio of 3 to 4 to 5 is usually employed (e.g., 15′ × 20′ × 25′). The walls, floor, and ceiling are lined with a sound-absorbing material.

dead short—A short circuit having minimum resistance.

dead space—1. An area or zone, within the normal range of a radio transmitter, in which no signal is received. 2. *See* Dead Band.

dead spot—1. A geographic location in which signals from one or more radio stations are received poorly or not at all. 2. That portion of the tuning range of a receiver where stations are heard poorly or not at all because of poor sensitivity.

dead time—The minimum interval, following a pulse, during which a transponder or component circuit is incapable of repeating a specified performance.

dead volume—The total volume of the pressure port cavity of a pressure transducer at the rest position (i.e., with no stimulus applied).

dead zone—1. The range of values over which no corrective action will take place in an automatic control system. 2. *See* Dead Band.

deafness—*See* Hearing Loss.

debug—To examine or test a procedure, routine, or equipment for the purpose of detecting and correcting errors.

debugging — 1. Isolating and removing all malfunctions ("bugs") from a computer or other device to restore its operation. 2. A process undertaken to carry an equipment or a group of parts through the initial period during which catastrophic-type failures occur at an abnormally high rate.

debugging period—*See* Early Failure Period.

debunching—Space-charge effect that tends to destroy the electron bunching in a velocity-modulation vacuum tube by spreading the beam due to mutual repulsion of the electrons.

Debye length—A theoretical length that describes the maximum separation at which a given electron is influenced by the electric field of a given positive ion. Also called Debye shielding distance or plasma length.

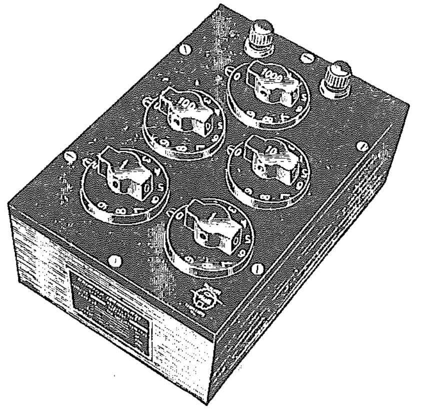
Debye shielding—*See* Debye Length.

decade—1. The interval between any two quantities having a ratio of 10:1. 2. A group or assembly of 10 units (e.g., a counter which counts to 10 in one column, or a resistor box which inserts resistance quantities in multiples of powers of 10).

decade band—A band having frequency limits related by the equation $f_b - f_a = 10$.

decade box—A special assembly of precision resistors, coils, or capacitors. It contains two or more sections, each having 10 times the value of the preceding section. Each section is divided into 10 equal parts. By means of a 10-position selector switch or equivalent arrangement, the box can be set to any desired value in its range.

decade counter—*See* Decade Scaler.



Decade resistance box.

decade resistance box—A resistance box containing two or more sets of 10 precision resistors.

decade scaler—Counter or scale-of-ten counter. A scaler with a factor of 10. It produces one output pulse for every 10 input pulses.

decalesent point—The temperature at which there is a sudden absorption of heat as the temperature of a metal is raised.

decametric waves—High-frequency band; 3 MHz to 30 MHz.

decay—1. Gradual reduction of a quantity. 2. The decrease in the radiation intensity of any radioactive material with respect to time. 3. In a storage tube, a change in magnitude or configuration of stored information by any cause other than erasing or writing.

decay characteristic—*See* Persistence Characteristic (of a luminescent screen).

decay distance — The distance between an area of wave generation and a point of passage of the resulting waves outside the area.

Decca—A British long-range hyperbolic navigational system that operates in the 70- to 130-kilohertz frequency band. It is a continuous-wave system in which the receiver measures and integrates the relative phase difference between the signal received from two or more synchronized ground stations. One master station and three slave stations are usually arranged in stat formation. Operational range is about 250 miles.

decelerated electrons — Electrons which, after traveling at a great rate of speed, strike a target, become quickly decelerated, and cause the target to emit X rays.

decelerating electrode—In an electron-beam tube, an electrode to which a potential is applied to slow down the electrons in the beam.

deceleration—The act or process of moving, or of causing to move, with decreasing speed; the state of so moving.

deceleration time—In a computer, the time interval between the completion of the reading or writing of a record on a magnetic tape and the time when the tape stops moving.

deception—Deliberate production of false or misleading echoes on enemy radar by the radiation of spurious signals synchronized to the radar or by the reradiation of the radar pulses from extraneous reflectors.

deception device – A device that works to make unfriendly signals either unusable or misleading.

deci—Prefix meaning one-tenth (10^{-1}).

decibel—Abbreviated db. The standard unit for expressing transmission gain or loss and relative power levels. The term "dbm" is used, when a power of one milliwatt is the reference level. Db indicates the ratio of power output to power input:

$$db = 10 \log_{10} \frac{P_1}{P_2}$$

One decibel is 1/10 of a bel.

decibel meter—Also called db meter. An instrument for measuring the electric power level, in decibels, above or below an arbitrary reference level.

decibels above or below 1 milliwatt – The unit used to describe the ratio of the power at any point in a transmission system to a reference level of 1 milliwatt. The ratio expresses decibels above or below this reference level of 1 milliwatt.

decibels above or below 1 watt—A measure of power expressed in decibels to a reference level of 1 watt.

decibels above reference noise—An expression used to describe the ratio of the circuit noise level in a transmission system, at any point, to some arbitrarily chosen reference noise. The expression signifies the reading of a noise meter. Where the circuit noise meter has been adjusted to represent effect under specified conditions, the expression is in adjusted decibels.

decilog—A division of the logarithmic scale used for measuring the logarithm of the ratio of two values of any quantity. The number of decilogs is equal to 10 times the logarithm to the base 10 of the ratio. One decilog therefore corresponds to a ratio of $10^{0.1}$ (i.e. 1.25892+).

decimal—1. Pertaining to a characteristic or property involving a selection, choice, or condition in which there are 10 possibilities. 2. Pertaining to the number representation system with a radix of 10.

decimal attenuator—A system of attenuators arranged so that a voltage or current can be reduced decimally.

decimal notation—The writing of quantities in the decimal numbering system.

decimal numbering system – The popular numbering system using the Arabic numerals 0 through 9 and thus having a base, or radix, of 10. For example, the decimal number 2,345 can be derived in this way:

$$2{,}000 + 300 + 40 + 5 = 2{,}345 \text{ or:}$$

$$2\,(10^3) + 3\,(10^2) + 4\,(10^1) + 5\,(10^0) = 2{,}345.$$

In the decimal system, all numbers are obtained by raising the radix (total number of marks, or 10 in this system) to various powers.

decimal point—In a decimal number, the point which marks the place between integral and fractional powers of 10.

decimal-to-binary conversion – The mathematical process of converting a number written in the scale of 10 into the same number written in the scale of 2.

decimetric waves—1. Electromagnetic waves having wavelengths between 0.1 and 1 meter. 2. Ultrahigh frequency band; 300 MHz to 3 GHz.

decineper—One-tenth of a neper.

decinormal calomel electrode – A calomel electrode containing a decinormal potassium chloride solution.

decision—In a computer, the process of determining further action on the basis of the relationship of two similar items of data.

decision box—On a flowchart, a rectangle or other symbol used to mark a choice or branching in the sequence of programming of a digital computer.

decision element – In computers or data-handling systems, a circuit which performs a logical operation—such as AND, OR, NOT, or EXCEPT on one or more binary digits of input information which represent "yes" or "no"—and expresses the result in its output.

declination—The angular difference between the position of a compass needle and the true position of geographical north and south.

declinometer—Also called a compass declinometer. A device for measuring the direction of a magnetic field relative to astronomical or survey coordinates.

decode—In a computer, to obtain a specific output when specific character-coded input lines are activated.

decoder—1. A device for decoding a series of coded signals. 2. In automatic telephone switching, a relay-type translator which determines from the office code of each call the information required for properly recording the call through the switching train. Each decoder has means, such as a cross-connecting field, for establishing the controls desired and readily changing them. 3. Sometimes called matrix. In an electronic computer, a network or system in which a combination of inputs is excited at one time to produce a single output.

decoding—1. The process of obtaining intelligence from a code signal. 2. In multiplex, a process of separating the subcarrier from the main carrier.

decommutation—The process of recovering a signal from the composite signal previously created by a commutation process.

decommutator – Equipment for separating, demodulating, or demultiplexing commutated signals.

decoupling—The reduction of coupling.

decoupling circuit—A circuit used to prevent interaction of one circuit with another.

decoupling network—A network of capacitors and chokes or resistors placed into leads which are common to two or more circuits, to prevent unwanted, harmful interstage coupling.

decoy—A reflecting object used in radar deception, having reflective characteristics of a target.

decrement—1. Progressive diminution in the value of a variable quantity; also the amount by which a variable decreases. When applied to damped oscillations, it is usually called damping factor. 2. A specific part of an instruction word in some binary computers, thus a set of digits.

dee – A hollow, D-shaped accelerating electrode in a cyclotron.

dee line—A structural member that supports the dee of a cyclotron and together with the dee forms the resonant circuit.

de-emphasis—Also called post-emphasis or post-equalization. Introduction of a frequency-response characteristic which is complementary to that introduced in pre-emphasis.

de-emphasis network—A network inserted into a system to restore the pre-emphasized frequency spectrum to its original form.

de-energize—To disconnect a device from its power source.

deep discharge—The withdrawal of all available electrical energy before recharging a cell or battery.

defect – A condition considered potentially hazardous or operationally unsatisfactory and therefore requiring attention.

defect conduction—Hole conduction in the valence band in a semiconductor.

defibrillator—A device used to eliminate fibrillation (irregular beating) of the heart muscle by the application of high-voltage impulses.

definite-purpose relay – A relay with some electrical or mechanical feature which distinguishes it from a general-purpose relay.

definition—1. The fidelity with which the detail of an image is reproduced. When the image is sharp (i.e., has definite lines and boundaries), the definition is said to be good. 2. The degree with which a communication system reproduces sound images or messages.

deflecting coil—An inductor used to produce a magnetic field that will bend the electron beam a desired amount in the cathode-ray tube of an oscilloscope, television receiver, or television camera.

deflecting electrode—An electrode to which a potential is applied in order to deflect an electron beam.

deflecting torque—*See* Torque of an Instrument.

deflection—Movement of the electron beam in a cathode-ray tube as electromagnetic or electrostatic fields are varied to cause the light spot to traverse the face of the tube in a predetermined pattern.

deflection coil—One of the coils in the deflecting yoke.

deflection factor—*See* Deflection Sensitivity.

deflection plane—A plane perpendicular to the cathode-ray-tube axis and containing the deflection center.

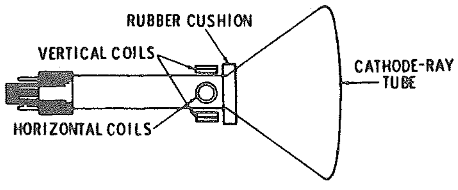
deflection plates—Two pairs of parallel electrodes, the pairs set one forward of the other and at right angles to each other, parallel to the axis of the electron stream within an electrostatic cathode-ray tube. An applied potential produces an electric field between each pair. By varying the applied potential, this field may be varied to cause a desired angular displacement of the electron stream.

deflection polarity – The relationship between the direction of displacement of an oscilloscope trace and the polarity of the applied signal wave.

deflection polarity of an oscilloscope—The relationship between the direction of a displacement of the cathode beam and the polarity of the applied signal wave.

deflection sensitivity—Also called deflection factor. The displacement of the electron beam at the target or screen of a cathode-ray tube divided by the change in magnitude of the deflecting field. Deflection sensitivity is usually expressed in millimeters (or inches) per volt applied between the deflecting electrodes, or in millimeters (or inches) per ampere in the deflection coil.

deflection voltage—The voltage applied to the electrostatic plates of a cathode-ray tube to control the movement of the electron beam.



Deflection yoke.

deflection yoke—An assembly of one or more electromagnets for deflecting one or more electron beams.

degassing—The process of driving out and exhausting the gases of an electron tube occluded in its internal parts.

degausser—Also called automatic degausser and bulk eraser. A device to clarify the color picture by means of coils within the set. The coils deactivate the magnetization which builds up around a color tv set when it is moved around, or when other electrical devices are brought too close to the receiver.

degaussing—Girdling a ship's hull with a web of current-carrying cable that sets up a magnetic field equal in value and opposite in polarity to that induced by the earth's magnetic field, thus rendering the ship incapable of actuating the detonator of a magnetic mine.

degeneracy—The condition in which two or more modes have the same resonant frequency in a resonant device.

degenerate modes—A set of modes having the same resonance frequency (or propagation constant). The members of a set of degenerate modes are not unique.

degenerate parametric amplifier — An inverting parametric device for which the two signal frequencies are identical and equal to one-half the frequency of the pump. (This exact but restrictive definition is often relaxed to include cases where the signals occupy frequency bands which overlap.)

degeneration—*See* Negative Feedback.

degradation—A gradual decline of quality or loss of ability to perform within required limits. The synonym "drift" is often used for electronic devices.

degradation failure—Failure resulting from a gradual change in the performance characteristics of a device or part.

degree of current rectification—The ratio between the average unidirectional current output and the root-mean-square value of the alternating-current input from which it was derived.

degree of voltage rectification—The ratio between the average unidirectional voltage and the root-mean-square value of the alternating voltage from which it was derived.

deion circuit breaker — A circuit breaker built so that the arc that forms when the circuit is broken is magnetically blown into a stack of insulated copper plates, giving the effect of a large number of short arcs in series. Each arc becomes almost instantly deionized when the current drops to zero in the alternating-current cycle, and the arc cannot re-form.

deionization—The process by which an ionized gas returns to its neutral state after all sources of ionization have been removed.

deionization potential — The potential at which ionization of the gas within a gas-filled tube ceases and conduction stops.

deionization time—The time required for the grid of a gas tube to regain control after the anode current has been interrupted.

dekahexadecimal—*See* Sexidecimal Notation.

Dekatron—A cold-cathode counting tube.

delay—The time required for a signal to pass through a device or conductor.

delay circuit—A circuit which delays the passage of a pulse or signal from one part of a circuit to another.

delay coincidence circuit — A coincidence circuit actuated by two pulses, one of which is delayed a specific amount with respect to the other.

delay counter—In a computer, a device that can temporarily delay a program a sufficient length of time for the completion of an operation.

delay distortion — 1. Phase-delay distortion (i.e., departure from flatness in the phase delay of a circuit or system over the frequency range required for transmission, or the effect of such departure on a transmitted signal). 2. Also called envelope delay distortion or phase delay. Envelope distortion (i.e., departure from flatness in the envelope delay of a circuit or system over the frequency range required for transmission, or the effect of such departure on a transmitted signal). 3. The amount of variation in delay for various frequency components of the facsimile signal, usually expressed in microseconds from an average delay time.

delayed automatic volume control—Abbreviated delayed avc. An automatic volume-control circuit that acts only on signals above a certain strength. It thus permits reception of weak signals even though they may be fading, whereas normal automatic volume control would make the weak signals even weaker.

delayed avc—*See* Delayed Automatic Volume Control.

delayed contacts—Contacts which are actuated a predetermined time after the start of a (timing) cycle.

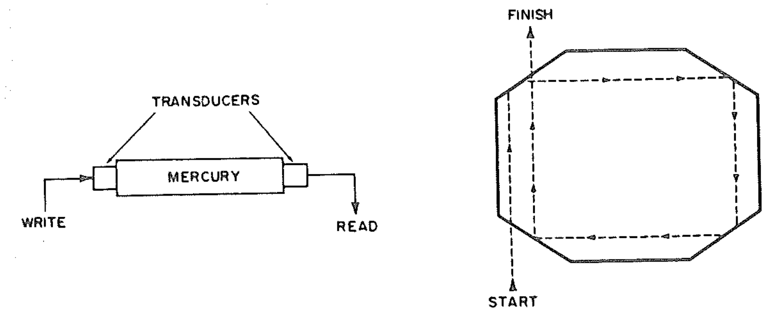
delayed ppi—A ppi (plan-position indicator) in which the initiation of the time base is delayed.

delayed repeater satellite—A satellite which stores information obtained from a ground terminal at one location and, upon interrogation by a terminal at a different location, transmits the stored message.

delayed sweep—1. In a cathode-ray tube, a type of sweep which is not allowed to begin for a while after being triggered by the initiating pulse. 2. A sweep that has been delayed either by a predetermined period or by a period determined by an additional independent variable.

delay equalizer—1. A device which adds delay at certain frequencies to a circuit in a way to reduce the delay distortion. 2. A corrective network which is designed to make the phase delay or envelope delay of a circuit or system substantially constant over a desired frequency range.

delay/frequency distortion—That form of distortion which occurs when the envelope delay of a circuit or system is not constant over the frequency range required for transmissions.



Mercury type.

Prism type.

Delay lines.

delay line—1. A real or artificial transmission line or equivalent device designed to delay a signal or wave for a predetermined length of time. 2. A specially constructed cable used in the luminance channel of a color receiver to delay the luminance signal.

delay-line memory—*See* Delay-Line Storage.

delay-line register—An acoustic or electric delay line in an electronic computer, usually one or an integral number of words in length, together with input, output, and circulation circuits.

delay-line storage—Also called delay-line memory. In an electronic computer, a storage or memory device consisting of a delay line and a means for regenerating and reinserting information into it.

delay multivibrator—A monostable multivibrator that produces an output pulse a predetermined time after it is triggered by an input pulse.

delay relay—Also called time-delay relay. A relay in which there is a delay between the time it is energized or de-energized and the contacts open or close.

delay time—The amount of time one signal is behind (lags) another.

delay timer—A term sometimes used to designate a timer which is primarily used for energizing (or de-energizing) a load at the end of a timed period. (*See* Time Delay Relay—preferred meaning.)

delay unit—The unit of a radar system in which pulses may be delayed a controllable amount.

deletion record—In a computer, a new record to replace or remove an existing record in a master file.

delimiter—1. In a computer, a character that limits a string of characters and therefore cannot be a member of the string. 2. Also called separator. A flag that separates and organizes items of data.

Dellinger effect—*See* Radio Fadeout.

delta—1. The Greek letter delta (Δ) represents any quantity which is much smaller than any other quantity of the same units appearing in the same problem. 2. In a magnetic cell, the difference between the partial-select outputs of the same cell in a one state and in a zero state.

delta circuit—A three-phase circuit in which the windings of the system are connected in the form of a closed ring, and the instantaneous voltages around the ring equal zero. There is no common or neutral wire, so the system is used only for three-wire systems or generators.

delta connection—In a three-phase system, the terminal connections. So called because they are triangular like the Greek letter delta.

delta match—*See* Y Match.

delta matched antenna—Also called Y antenna. A single-wire antenna (usually one half-wavelength long) to which the leads of an open-wire transmission line are connected in the shape of a Y. The flared part of the Y matches the transmission line to the antenna. The top of the Y is not cut, giving the matching section its triangular shape of the Greek letter *delta*, hence the name.

delta matching transformer—An impedance device used to match the impedance of an open-wire transmission line to an antenna. The two ends of the transmission line are fanned out so that the impedance of the line gradually increases. The ends of the transmission line are attached to the antenna at points of equal impedance, symmetrically located with respect to the center of the antenna.

delta modulation — A means of encoding analog signals in control and communication systems. The output of the delta encoder is a single weighed digital pulse train which may be decoded at the receiving end to reconstruct an original analog signal.

delta network—A set of three branches connected in series to form a mesh.

delta pulse code modulation—A modulation system that converts audio signals into corresponding trains of digital pulses to provide greater freedom from interference during transmission over wire or radio channels.

delta wave—A brain wave the frequency of which is below 9 hertz.

dem—Abbreviation for demodulator.

demagnetization—Partial or complete reduction of residual magnetism.

demagnetization curve—In the second quadrant of a hysteresis loop, the portion which lies between the residual induction point, B_r, and the coercive force point, H_c.

demagnetization effect—A decrease in internal magnetic field caused by uncompensated magnetic poles at the surface of a sample.

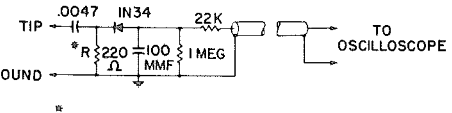
demagnetizer—A device for removing the magnetism which may build up in a recording or playback head.

demagnetizing force—A magnetizing force applied in such a direction that it reduces the residual induction in a magnetized body.

Dember effect—Also known as the photodiffusion effect. The production of a potential difference between two regions of a semiconductor specimen when one is illuminated. This phenomenon is related to the photoelectromagnetic effect, except there is no magnetic field. H. Dember discovered when an illuminated metal plate, producing electrons, is bombarded by other electrons from an outside source, the photoelectric emission increases because, in addition to photoelectrons, secondary electrons are also knocked out by bombardment.

demodulation — Also called detection. The operation on a previously modulated wave in such a way that it will have substantially the same characteristics as the original modulating wave.

demodulator—1. A device which operates on a carrier wave to recover the wave with which the carrier was originally modulated. 2. A facsimile device which detects an amplitude-modulated signal and produces the modulating frequency as a direct current of varying amplitude. This type of unit is used to provide a keying signal for a frequency-shift exciter unit for radio facsimile transmission. 3. A device which receives tones from a transmission circuit and converts them to electrical pulses, or bits, which may be accepted by a business machine.



*R MAY BE INCREASED IN VALUE TO REDUCE CIRCUIT LOADING

Demodulator probe.

demodulator probe—A probe designed for use with an oscilloscope, for displaying modulated high-frequency signals.

demountable tube — A high-power electron tube having a metal envelope with porcelain insulation. Can be taken apart for inspection and for renewal of electrodes.

demultiplexer—A device used to separate two or more signals that were previously combined by a compatible multiplexer and are transmitted over a single channel.

demultiplexing circuit — A circuit that is used to separate the signals that have been combined for transmission by multiplex.

denary band — A band having frequency limits with the ratio of $f_b/f_a = 10$.

dendrite — A semiconductor crystal with a heavily-branched, tree-like structure which grows from the nucleus as the metal becomes solidified.

dendritic growth—A technique of producing semiconductor crystals in long, uniform ribbons with optically flat surfaces.

dense binary code—A binary code in which all the possible states of the pattern are used.

densitometer—An instrument for measuring the optical density (photographic transmission, photographic reflection, visual transmission, and so forth) of a material.

density—1. A measure of the light-reflecting or -transmitting properties of an area. 2. The mass per unit volume. The specific gravity of a body is the ratio of a density to the density of a standard substance. Water and air are commonly used as the standard substances. 3. Amount per unit cross-sectional area (e.g., current, magnetic flux, or electrons in a beam).

density modulation—Modulation of an electron beam by varying the density of the electrons in the beam with time.

dentaphone—A device by which deaf persons can hear sounds via the teeth.

dependent linearity—Nonlinearity errors expressed as a deviation from a desired straight line of fixed slope and/or position.

depletion field-effect transistor (FET) — An active semiconductor device in which the main current is controlled by the depletion width of a P-N junction.

depletion layer—Also called barrier layer. In a semiconductor, the region in which the mobile-carrier charge density is insufficient to neutralize the net fixed charge density of donors and acceptors.

depletion-layer capacitance — Also called barrier capacitance. Capacitance of the depletion layer of a semiconductor. It is a function of the reverse voltage.

depletion-layer rectification — Also called barrier-layer rectification. The rectification that appears at the contact between dissimilar materials, such as a metal-to-semiconductor contact or a PN junction, as the energy levels on each side of the discontinuity are readjusted.

depletion-layer transistor—Any of several types of transistors which rely directly for their operation on the motion of carriers through depletion layers (for example, a spacistor).

depletion region—Also referred to as the space charge, barrier, or intrinsic region. In a semiconductor, the region containing the acceptor and donor ions the excess holes or electrons of which have been removed.

depolarization—The process of preserving the activity of a primary cell by the addition of a substance to the electrolyte. This substance combines chemically with the hydrogen gas as it forms, thus preventing excessive buildup of hydrogen bubbles.

depolarizer—A chemical used in some primary cells to prevent formation of hydrogen bubbles at the positive electrode.

deposition — The application, usually in a vacuum, of a material to a substrate by means of an electrical, chemical, screening, or vapor method.

depth finder—*See* Fathometer.

depth of cut—The depth to which the recording stylus penetrates the lacquer of a recording disc.

depth of heating—The depth at which effective dielectric heating can be confined below the surface of a material when the applicator electrodes are placed adjacent to only one surface.

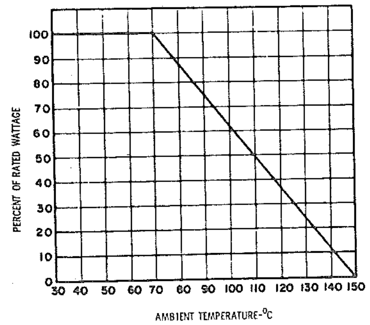
depth of modulation—In a radio-guidance system obtaining directive information from the two spaced lobes of a directional antenna, the ratio of the difference in total field strength of the two lobes to the field strength of the greater lobe at a given point in space.

depth of penetration—The thickness of a layer extending inward from the surface of a conductor and having the same resistance to direct current as the whole conductor has to alternating current of a given frequency.

depth sounder—*See* Fathometer.

de-Q—To reduce the Q of a tuned circuit, as generally applied to carrier-current transmission systems.

derate—To reduce the voltage, current, or power rating of a device to improve its reliability or to permit operation at high ambient temperatures.



Derating curve.

derating—The reduction in rating of a device or component, especially the maximum power-dissipation rating at higher temperatures.

derating factor — The factor by which the ratings of component parts are reduced to provide additional safety margins in critical applications or when the parts are subjected to extreme environmental conditions for which their normal ratings do not apply.

derivative action—*See* Rate Action.

derivative control — Automatic control in which the rate of correction is determined by the rate at which the error producing it changes.

derived center channel — A monophonic composite signal derived from the sum or difference of the left and right stereo channels, often fed to an extra speaker to fill in an aural "hole" between the left and right speakers. The signal from a voltage-derived center-channel output must be fed to an external power amplifier before it can drive a speaker. A power-derived center channel can drive a speaker directly.

desensitization — 1. The saturation of one component (an amplifier, for instance) by another so that the first cannot perform its proper function. 2. The reduction in receiver sensitivity due to the presence of a high-level off-channel signal overloading the radio-frequency amplifier or mixer stages, causing automatic gain control action.

design-center rating—Values of operating and environmental conditions which should not be exceeded under normal conditions in a bogey electron device.

design for maintainability—Those features and characteristics of design of an item that reduce requirements for tools, test equipment, facilities, spares, highly skilled personnel, etc., and improve the capability of the item to accept maintenance actions.

design-maximum rating—Values of operating and environmental conditions which should not be exceeded under the worst possible conditions in a bogey electron device.

design proof test—A test used to verify that a design specification meets the overall functional requirements of the finished product.

Desk-Fax — Trade name of Western Union Telegraph Co. for a small facsimile transceiver employed principally in short-line telegraph service.

desk-top computer — A computer that requires no formally prepared stored program entered in a special language. Most desk-top computers are operated like adding machines or mechanical calculators.

destination register—In a computer, a register into which data is being placed.

Destriau effect—Sustained emission of light by suitable phosphor powders embedded in an insulator and subjected only to the action of an alternating electric field.

destructive read-out — In a computer, the destruction of data during the process of sensing.

destructive test — Any test resulting in the destruction or drastic deterioration of the test specimen.

detail—A measure of the sharpness of a recorded facsimile copy or reproduced image. Generally related to the number of lines scanned per inch. Defined as the square root of the ratio between the number of scanning lines per unit length and the definition in the direction of the scanning line.

detail contrast—The ratio of the amplitude of the high-frequency components of a video signal to the amplitude of the reference low-frequency component.

detection—*See* Demodulation.

detectophone—An instrument for secretly listening in on a conversation. A high-sensitivity, nondirectional microphone is concealed in the room and connected to an amplifier and headphones or recorder remotely located. Sometimes the microphone feeds into a wired-wireless transmitter that broadcasts over power lines, to permit the listener to be farther away.

detector — 1. A device for effecting the process of detection or demodulation. 2. A mixer or converter in a superheterodyne receiver; often referred to as a "first detector." 3. A device that produces an electrical output that is a measure of the radiation incident on the device. 4. A rectifier tube, crystal, or dry disc by which a modulation envelope on a carrier or the simple on-off state of a carrier may be made to drive a lower-frequency device.

detector balanced bias—A controlling circuit used in radar systems for anticlutter purposes.

detector circuit—That portion of a receiver which recovers the modulation signal from the r-f carrier wave.

detector probe—A probe containing a high-frequency rectifying element such as a crystal diode or a tube. Used with an oscilloscope, vacuum-tube voltmeter, or signal tracer for recovering the modulation from a carrier.

detent—1. A stop or other holding device, such as a pin, lever, etc., on a ratchet wheel. 2. Switch action typified by a gradual increase in force to a position at which there is an immediate and marked reduction in force.

detune—To change the inductance and/or capacitance of a tuned circuit and thereby cause it to be resonant at other than the desired frequency.

deuterium—Heavy hydrogen, so called because it weighs twice as much as ordinary hydrogen. The nucleus of heavy hydrogen is a deuteron.

deuteron—Also called deuton. The nucleus of an atom of heavy hydrogen (deuterium) containing one proton and one neutron. Deuterons are often used as atomic projectiles in atom smashers.

deviation—1. The difference between the actual and specified values of a quantity. 2. In frequency modulation, the difference between the instantaneous frequency during modulation and the carrier frequency. 3. A departure from specification requirements for which approval is obtained from the consumer prior to occurrence of the departure from specification requirements.

deviation absorption — Absorption that occurs at frequencies near the critical frequency. Occurs in conjunction with the slowing up of radio waves near the critical frequency, upon reflection from the ionosphere.

deviation distortion—Distortion caused by inadequate bandwidth, amplitude-modulation rejection, or discriminator linearity in an f-m receiver.

deviation ratio — In frequency modulation, the ratio of the maximum change in carrier frequency to the highest modulating frequency.

deviation sensitivity — The smallest frequency deviation that produces a specified output power in f-m receivers.

device—1. A single discrete conventional electronic device such as a resistor or transistor, or a microelectronic circuit. 2. Also called item. Any subdivision of a system.

device complexity—The number of circuit elements within an integrated circuit.

Dewar flask—A container with double walls. The space between the walls is evacuated, and the surfaces bounding this space are silvered.

dew point—The temperature at which condensation first occurs when a vapor is cooled.

DF—Abbreviation for direction finder or dissipation factor.

DF antenna—Any antenna combination included in a direction finder for obtaining the phase or amplitude reference of the received signal. May be a single or orthogonal loop, an adcock, or spaced differentially-connected dipoles.

DF antenna system—One or more DF antennas and their combining circuits and feeder systems, together with the shielding and all electrical and mechanical items up to the receiver input terminals.

Diac — Two-lead alternating-current switch semiconductor.

diagnostic routine—An electronic-computer routine designed to locate a malfunction in the computer, a mistake in coding, or both.

diagnotor — In a computer, combined diagnostic and edit routine that questions unusual situations and makes note of the implied results.

diagram—1. Schematics, prints, charts, etc., or any other graphical representation, the purpose of which is to explain rather than to represent. 2. A schematic representation of a sequence of subroutines designed to solve a problem. 3. A coarser and less symbolic representation than a flowchart, frequently including descriptions in English words. 4. A schematic or logical drawing showing the electrical circuit or logical arrangements within a component.

dial—1. A means for indicating the value to which a control knob has been set. 2. A calling device which generates the required number of pulses in a telephone set and thereby establishes contact with the party being called.

dial cable—*See* Dial Cord.

dial cord—Also called dial cable. A braided cord or flexible wire cable connected to a tuning knob so that turning the knob will move the pointer or dial which indicates the frequency to which a radio receiver is tuned. Also used for coupling two shafts together mechanically.

dial light—A small pilot lamp which illuminates the tuning dial of a radio receiver.

dial pulse—Interruption in the direct current flowing through the loop of a calling telephone, produced by the opening and closing of the dial pulse springs of a calling telephone in response to the dialing of a digit. The current in the calling-line loop is interrupted as many times as there are units in the digit dialed—i.e., dialing of the digit 7 generates seven dial pulses (interruptions) in current flowing through the loop of the calling telephone.

dial register — *See* Standard Register of a Motor Meter.

dial tone—A hum or other tone employed in a dial telephone system to indicate that the line is not busy and that the equipment is ready for dialing.

diamagnetic — Term applied to a substance with a negative magnetic susceptibility.

diamagnetic material—A material which is less magnetic than air, or in which the intensity of magnetization is negative. There is no known material in which this effect has more than a very feeble intensity. Bismuth is the leading example of materials of this class.

diamond antenna—Also called a rhombic antenna. A horizontal antenna having four conductors that form a diamond, or rhombus.

diamond lattice — The crystal structure of germanium and silicon (as well as a diamond).

diamond stylus—A phonograph pickup with a ground diamond as its point.

diapason — The unique fundamental tone color of organ music.

diaphragm—1. A flexible membrane used in various electroacoustic transducers for producing audio-frequency vibrations when actuated by electric impulses, or electric impulses when actuated by audio-frequency vibrations. (*Also see* Iris.) 2. In electrolytic cells, a porous or permeable membrane, usually flexible, separating the anode and cathode compartments. 3. In waveguide technique, a thin plate, or plates, placed transversely across the waveguide, not completely closing it, and usually introducing a reactance component.

diathermy — Therapeutic heating of tissues beneath the skin by applying an r-f current to some part of the body.

diathermy interference — A form of television interference caused by diathermy equipment, resulting in a horizontal herringbone pattern across the picture.

diathermy machine — A medical apparatus consisting of an r-f oscillator frequently followed by r-f amplifier stages, used to generate high-frequency currents that produce heat within some predetermined part of the body for therapeutic purposes.

dichroic mirror—A special mirror through which all light frequencies pass except those for the color which the mirror is designed to reflect.

dichroism—A property of an optical material which causes light of some wavelengths to be absorbed when the incident light has its electric-field vector in a particular orientation and not absorbed when the electric-field vector has other orientations.

dicing—The process of sawing a crystal wafer into blanks.

die—*See* Chip.

die bonding — A bonding process in which chips are soldered to the substrate.

dielectric — 1. The insulating (nonconducting) medium between the two plates of a capacitor. Typical dielectrics are air, wax-impregnated paper, plastic, mica, and ceramic. A vacuum is the only perfect dielectric. 2. A medium capable of recovering, as electrical energy, all or part of the energy required to establish an electric field (voltage stress). The field, or voltage stress, is accompanied by displacement or charging currents.

dielectric absorption—Also called dielectric hysteresis or dielectric soak. A characteristic of dielectrics which determines the length of time a capacitor takes to deliver the total amount of its stored energy. It manifests itself as the reappearance of a potential on the electrodes after the capacitor has been discharged. Its magnitude depends on the charge and discharge time of the capacitor.

dielectric amplifier—An amplifier employing a device similar to an ordinary capacitor, but with a polycrystalline dielectric which exhibits a ferromagnetic effect.

dielectric antenna—An antenna in which a dielectric is the major component producing the required radiation pattern.

dielectric breakdown — An abrupt increase in the flow of electric current through a dielectric material as the applied electric field strength exceeds a critical value.

dielectric breakdown voltage—The voltage between two electrodes at which electric breakdown of the specimen occurs under prescribed test conditions. Also called electric breakdown voltage, breakdown voltage, or hi-pot.

dielectric capacity—The inductivity or specific inductive capacity of a substance, being its ability to convey the influence of an electrified body.

dielectric constant—The ratio of the capacitance of a capacitor with the given dielectric to the capacitance of a capacitor having air for its dielectric but otherwise identical. Also called permittivity, specific inductive capacity, or capacitivity.

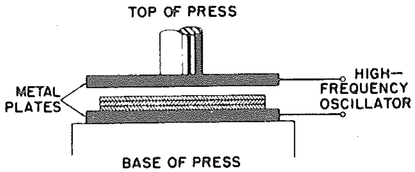
dielectric current—The current flowing at any instant through the surface of an isotropic dielectric which is in a changing electric field.

dielectric dissipation—*See* Loss Tangent.

dielectric dissipation factor—The cotangent of the dielectric phase angle of a material.

dielectric fatigue—The property of some dielectrics in which the insulating quality decreases after a voltage has been applied for a considerable length of time.

dielectric guide—A waveguide made of a solid dielectric material through which the waves travel.



Dielectric heating.

dielectric heating—A method of raising the temperature of a nominally insulating material by sandwiching it between two plates to which an r-f voltage is applied. The material acts as a dielectric, and its internal losses cause it to heat up.

dielectric hysteresis—*See* Dielectric Absorption.

dielectric isolation—The electrical isolation of monolithic integrated circuit elements from each other by dielectric material rather than by reverse biased P-N junctions.

dielectric lens—A lens used with microwave antennas; it is made of dielectric material so that it refracts radio waves similar to the way an optical lens refracts light waves.

dielectric loss—The power dissipated by a dielectric as the friction of its molecules opposes the molecular motion produced by an alternating electric field.

dielectric loss angle — The complement of the dielectric phase angle (i.e., the dielectric phase angle minus 90°).

dielectric loss factor — The product of the dielectric constant of a material times the tangent of the dielectric loss angle. Also called dielectric loss index.

dielectric loss index — *See* Dielectric Loss Factor.

dielectric matching plate — In waveguide technique, a dielectric plate used as an impedance transformer for matching purposes.

dielectric mirror—A highly frequency-selective, multilayer dielectric reflector acting by partial reflection of light at the interface between materials of unequal refractive indices.

dielectric phase angle—The angular difference in phase between the sinusoidal alternating voltage applied to a dielectric and the component of the resultant alternating current having the same period.

dielectric phase difference — *See* Dielectric Loss Angle.

dielectric polarization—*See* Polarization, 3.

dielectric power factor—The cosine of the dielectric phase angle.

dielectric rating—Standard test voltages and frequencies above which failure occurs between specified points in a relay structure.

dielectric soak—*See* Dielectric Absorption.

dielectric strength—The maximum voltage a dielectric can withstand without rupturing. Usually expressed as volts per mil. Also called: electric strength, breakdown strength, and electric field strength.

dielectric susceptibility—The ratio of the polarization in a dielectric to the electric intensity responsible for it.

dielectric tests—1. Tests which consist of the application of a voltage higher than the rated voltage for a specified time for the purpose of determining the adequacy against breakdown of insulating materials and spacings under normal conditions. 2. The testing of insulating materials by the application of a constantly increasing voltage until failure occurs.

dielectric waveguide—A waveguide constructed from a dielectric (nonconductive) substance.

difference amplifier—*See* Differential Amplifier.

difference channel—In a stereophonic sound system, an audio channel that handles the difference between the signals in the left and right channels.

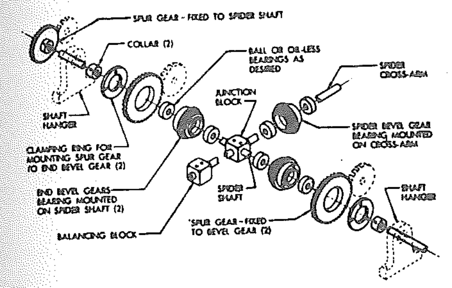
difference detector—A detector circuit in which the output is a function of the difference between the peak or rms amplitudes of the input waveforms.

difference frequency—1. A signal representing, in essence, the difference between the left and right sound channels of a stereophonic sound system. 2. One of the output frequencies of a converter. It is the difference between the two input frequencies.

difference in depth modulation—In directive systems employing overlapping lobes with modulated signals, a ratio obtained by subtracting from the percentage of modulation of the larger signal the percentage of modulation of the smaller signal and dividing by 100.

difference of potential—The voltage or electrical pressure existing between two points. It will result in a flow of electrons whenever a circuit is established between the two points.

differential — 1. A planetary gear system which adds or subtracts angular movements transmitted to two components and delivers the answer to a third. Widely used for adding and subtracting shaft movements in servo systems and for addition and subtraction in computing machines. 2. In electronics, the difference between two levels.



SPUR GEAR - FIXED TO SPIDER SHAFT
COLLAR (2)
BALL OR OIL-LESS BEARINGS AS DESIRED
SPIDER CROSS-ARM
JUNCTION BLOCK
SHAFT HANGER
SPIDER BEVEL GEAR BEARING MOUNTED ON CROSS-ARM
CLAMPING RING FOR MOUNTING SPUR GEAR TO END BEVEL GEAR (2)

SHAFT HANGER
SPUR GEAR - FIXED TO BEVEL GEAR (2)
BALANCING BLOCK

Differential.

differential amplifier—An amplifier having two similar input circuits so connected that they respond to the difference between two voltages or currents, but effectively suppress like voltages or currents.

differential angle—The total angle from the operation to the releasing position in a mercury switch.

differential analyzer — 1. A mechanical or electrical device primarily designed and used to solve differential equations. 2. An analog computer designed primarily for solving or analyzing many types of differential equations.

differential capacitance — The derivative with respect to voltage of a capacitor charge characteristic at a given point on the curve.

differential capacitance characteristic — The function that relates differential capacitance to voltage.

differential capacitor—A variable capacitor having two similar sets of stator plates and one set of rotor plates. When the rotor is turned, the capacitance of one section is increased while the capacitance of the other section is decreased.

differential cooling—A lowering of temperature which takes place at a different rate at various points on an object or surface.

differential delay — The difference between the maximum and the minimum frequency delays occurring across a band.

differential discriminator—A discriminator that passes only pulses having amplitudes between two predetermined values, neither of which is zero.

differential duplex system—A duplex system in which the sent currents divide through two mutually inductive sections of the receiving apparatus. These sections are connected respectively to the line and to a balancing artificial line in opposite directions. Hence, there is substantially no net effect on the receiving apparatus. The received currents pass mainly through one section, or through the two sections in the same direction, and operate the apparatus.

differential flutter — Speed-change errors which occur at different magnitudes, frequencies, or phases across the width of a magnetic tape.

differential gain—The ratio of the differential output signal of a differential amplifier divided by the differential input signal causing that output.

differential gain control—Also called gain-sensitivity control. A device for altering the gain of a radio receiver in accordance with an expected change of signal level, in order to reduce the amplitude differential between the signals at the receiver output.

differential galvanometer—A galvanometer having two similar but opposed coils, so that their currents tend to neutralize each other. A zero reading is obtained when the currents are equal.

differential gap—The difference between two target values, one of which applies to an upswing of conditions and the other to a downswing.

differential generator—A synchro differential generator driven by a servo system.

differential impedance — The internal impedance observed between the input terminals of an operational amplifier.

differential input—An input circuit that rejects voltages which are the same at both input terminals and amplifies the voltage difference between the two input terminals. May be either balanced or floating and may also be guarded.

differential-input amplifier — An amplifier in which the output is ideally a function only of the difference between the signals applied to its two inputs, both signals being measured with respect to a common "low" or "ground" reference point.

differential-input capacitance—The capacitance between the inverting and noninverting input terminals.

differential-input impedance — The impedance between the inverting and noninverting input terminals of a differential amplifier.

differential-input measurement — Also called floating input. A measurement in which the two inputs to a differential amplifier are connected to two points in a circuit under test and the amplifier displays the difference voltage between the points. In this type of measurement, each input of the amplifier acts as a reference for the other, and ground connections are used only for safety reasons.

differential-input resistance — The resistance between the inverting and noninverting input terminals of a differential amplifier.

differential-input voltage — The maximum voltage that can be applied across the input terminals of a differential amplifier without damaging the amplifier.

differential-input voltage range—The range of voltages that may be applied between input terminals without forcing the circuit to operate outside its specifications.

differential-input voltage rating – The maximum allowable signal that may be applied between the inverting and noninverting inputs of a differential amplifier without damaging the amplifier.

differential instrument—A galvanometer or other measuring instrument having two circuits or coils, usually identical, through which currents flow in opposite directions. The difference or differential effect of these currents actuates the indicating pointer.

differential microphone—*See* Double-Button Carbon Microphone.

differential-mode signal—A signal that is applied between the two ungrounded terminals of a balanced three-terminal system.

differential modulation—A type of modulation in which the choice of the significant condition for any signal element is dependent on the choice for the previous signal element.

differential permeability—The ratio of the positive increase of normal induction to the positive increase of magnetizing force when these increases are minute.

differential phase—The difference in phase shift through a television system for a small, high-frequency sine-wave signal at two stated levels of a low-frequency signal on which the first signal is superimposed.

differential phase-shift keying—A modulation scheme in which the information is conveyed by changes in carrier phase during one interval relative to the preceding interval.

differential pressure – The difference in pressure between two pressure sources.

differential pressure transducer – A pressure transducer that accepts simultaneously two independent pressure sources, and the output of which is proportional to the pressure difference between the sources.

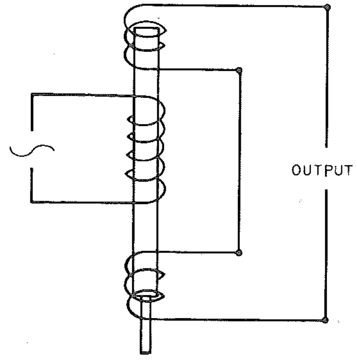
differential protective relay – A protective device which functions on a percentage or phase angle or other quantitative difference of two currents or of some other electrical quantities.

differential relay – A relay with multiple windings that functions when the voltage, current, or power difference between the windings reaches a predetermined value. The power difference may result from the algebraic addition of the multiple inputs.

differential selsyn—A selsyn in which both the rotor and the stator have similar windings that are spread 120° apart. The position of the rotor corresponds to the algebraic sum of the fields produced by the stator and rotor.

differential synchro—*See* Synchro Differential Generator *and* Synchro Differential Motor.

differential transducer—A device capable of simultaneously measuring two separate stimuli and providing an output proportionate to the difference between them.



Differential transformer.

differential transformer—Also called linear variable-differential transformer. 1. A transformer used to join two or more sources of signals to a common transmission line. 2. An electromechanical device which continuously translates displacement or position change into a linear a-c voltage.

differential voltage gain—The ratio of the change in output signal voltage at either terminal or a differential device to the change in signal voltage applied to either input terminal, all voltages measured to ground.

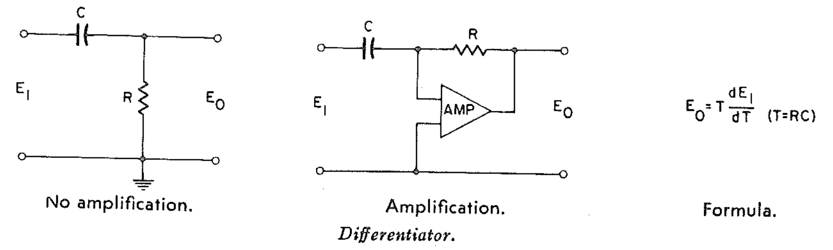
differential winding—A coil winding so arranged that its magnetic field opposes that of a nearby coil.

differential-wound field—A type of motor or generator field having both series and shunt coils connected so they oppose each other.

differentiating circuit—Also called differentiator.

differentiating network—*See* Differentiator.

differentiator—1. An analog computer device which produces an output proportional to the derivative of the one variable with respect to another, usually time. 2. A transducer or circuit the output waveform of which is the time derivative of its input waveform. Such a transducer or circuit preceding a frequency modulator makes the combination a phase modulator, or following a phase detector makes the combination a frequency detector. Its ratio of output amplitude to input amplitude is proportional to the frequency, and its output phase leads its input phase by 90°. 3. A circuit which produces an output voltage substantially in proportion to the rate of change of the input voltage or current. Differentiating circuits employ time constants that are short compared to the duration of the pulse applied, thus differentiating the input pulse.



No amplification.

Amplification.

Formula.

Differentiator.

diffracted wave—A radio, sound, or light wave which has struck an object and been bent or deflected, other than by reflection or refraction.

diffraction—1. The bending of radio, sound, or light waves as they pass through an object or barrier, thereby producing a diffracted wave. 2. The phenomenon whereby waves traveling in straight paths bend around an obstacle.

diffused-alloy transistor—Also called drift transistor. A transistor in which the semiconductor wafer is subjected to gaseous diffusion to produce a nonuniform base region, after which alloy junctions are formed in the same manner as for an alloy-junction transistor. It may also have an intrinsic region to give a PNIP unit.

diffused-base transistor—Also called graded-base transistor. A type of transistor made by combining diffusion and alloy techniques. A nonuniform base region and the collector-to-base junction are formed by gaseous dissemination into a semiconductor wafer that constitutes the collector region. Then the emitter-to-base junction is formed by a conventional alloy process on the base side of the diffused wafer.

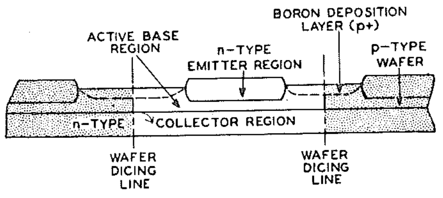
diffused device—A semiconductor device in which a base, usually of silicon, has successive layers of P and N characteristics diffused upon and into the base by means of a series of masks and around which P and N materials, usually phosphorus and boron, adhere to the base by gaseous diffusion in a high-temperature furnace. It is possible to build areas of resistance, capacitance, and "active" diodes and transistors into the base, creating an entire circuit. Performance is poor in the presence of radiation.

diffused-emitter-and-base transistor—Also called double-diffused transistor. A semiconductor wafer which has been subjected to gaseous dissemination of both N- and P-type impurities to form two PN junctions in the original semiconductor material.

diffused-emitter-and-collector transistor—A transistor in which both the emitter and collector are made by a dissemination process.

diffused junction—A junction formed by the dissemination of an impurity within a semiconductor crystal.

diffused-junction rectifier—A semiconductor diode in which the PN junction is produced by diffusion.



Diffused-junction silicon transistor wafer.

diffused-junction transistor—A transistor in which the emitter and collector electrodes have been formed by diffusion of an impurity into the semiconductor wafer without heating.

diffused-layer resistor – A resistor formed by including an appropriate pattern in the photomask to define diffusion areas.

diffused mesa transistor – A transistor in which the collector-base junction is formed by gaseous diffusion, and the emitter-base junction is formed either by gaseous diffusion or by an evaporated metal strip. The collector-base junction is then defined by etching away the undesired parts of the emitter and base regions, thus producing a mesa.

diffused planar transistor – A transistor made by two gaseous diffusions, but in which the collector-base junction is defined by oxide masking. Junctions are formed beneath this protective oxide layer with the result that the device has lower reverse currents and good d-c gain at low currents.

diffused sound—Sound which has uniform energy density, meaning the energy flux is equal in all parts of a given region.

diffused transistor – A transistor in which the emitter and collector junctions are both formed by diffusion.

diffused transmission—The total net transmission, by a medium or device, of light that is neither perfectly Lambertian nor parallel. Often used interchangeably with the term "gross transmission."

diffusion—1. The movement of carriers from a region of high concentration to regions of lower concentration. 2. Migration of atoms from one substance into another substance.

diffusion capacitance—The capacitance of a forward-biased PN junction.

diffusion constant—The quotient of diffusion-current density in a homogeneous semiconductor, divided by the charge-carrier concentration gradient. It is equal to the drift mobility times the average thermal energy per unit charge of carriers.

diffusion current – The current produced when charges move by diffusion.

diffusion length—In a homogeneous semiconductor, the average distance the minority carriers move between generation and recombination.

diffusion process—The method of producing junctions by disseminating acceptors or donors into a semiconductor at a high temperature.

diffusion transistor—A transistor relying on the dissemination of carriers, donors, or acceptors for carrying current.

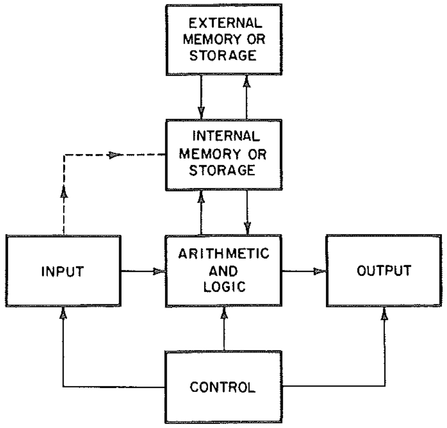
digiralt — A system of high-resolution radar altimetry in which pulse-modulated radar and high-performance time-to-digital conversion techniques are combined.

digit—One of the symbols, 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9, used in numbering in the scale of 10. One of these symbols, when used in a scale of numbering to the base *n*, expresses integral values ranging from *0* to *n—1* inclusive.

digital — Using numbers expressed in digits and in a certain scale of notation to represent all the variables that occur in a problem.

digital circuit—A circuit which operates like a switch—i.e., it is either "on" or "off."

digital communications—A system of telecommunications employing a nominally discontinuous signal that changes in frequency, amplitude, or polarity.



Block diagram of digital computer.

digital computer—An electronic calculator that operates with numbers expressed directly as digits, as opposed to the directly measurable quantities (voltage, resistance, etc.) in an analog computer. In other words, the digital computer counts (as does an adding machine); the analog computer measures a quantity (as does a voltmeter).

digital data — Data represented in discrete, discontinuous form, as contrasted with analog data represented in continuous form. Digital data are usually represented by means of coded characters (e.g., numbers, signs, symbols, etc.).

digital data-handling system — The electronic equipment which receives digital data, operates on it in a suitable manner, records it in a suitable manner, records it on a suitable medium, and presents it directly to a computer or a display.

digital information display—The presentation of digital information in tabular form on the face of a digital information display tube.

digital output—An output signal which represents the size of a stimulus or input signal in the form of a series of discrete quantities which are coded to represent digits in a system of numerical notation. This type of output is to be distinguished from one which provides a continuous rather than a discrete output signal.

digital phase shifter—A device which provides a signal phase shift by the application of a control pulse. A reversal of phase shift requires a control pulse of opposite polarity.

digital readout indicator—An indicator that reads directly in numerical form, as opposed to an analog indicator needle and scale.

digital rotary transducer—A rotating device utilizing an optical sensor that produces a serial binary output as a result of shaft rotation.

digital signals — Discrete or discontinuous signals whose various states are discrete intervals apart.

digital-to-analog converter — A computing device that changes digital quantities into physical motion or into a voltage (i.e., a number output into turns of a potentiometer).

digital voltmeter—An indicator which provides a digital readout of measured voltage rather than a pointer indication.

digit compression — In a computer, any of several techniques used to pack digits.

digitize—To convert an analog measurement of a physical variable into a number expressed in digits in a scale or notation.

digitizer—A device which converts analog data into numbers expressed in digits in a system of notation.

digit selector — In a computer, a device for separating a card column into individual pulses that correspond to punched row positions.

digit-transfer bus—The main wire or wires used to transfer information (but not control signals) among the various registers in a digital computer.

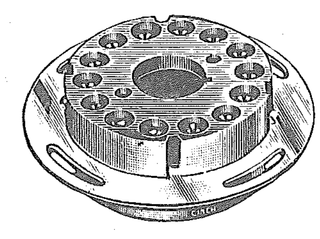
diheptal base—Also called diheptal socket. A vacuum-tube base having 14 pins (such as the base of a cathode-ray tube).

diheptal socket—*See* Diheptal Base.

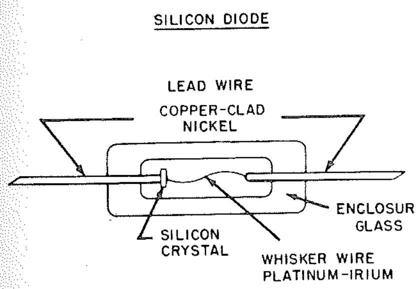
dimensional stability—The ability of a body to maintain precise shape and size.

dimmer—A control for varying the intensity of illumination of a pilot, scale, or dial light.

D-indicator—A radar indicator which combines Types B and C indicators. The signal appears as a bright spot, with azimuth angle as the horizontal coordinate and elevation angle as the vertical coordinate. Each horizontal trace is expanded vertically by a compressed time sweep to facilitate separation of the signal from noise and to give a rough range indication.



Diheptal socket.



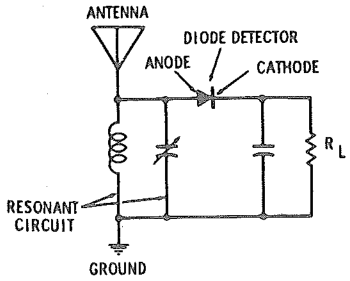
Diode.

diode—A two-terminal device which will conduct electricity more easily in one direction than in the other.

diode amplifier—A parametric amplifier that uses a special diode in a cavity. Used to amplify signals at frequencies as high as 6,000 MHz.

diode assembly—A single structure of more than one diode.

diode characteristic—The composite electrode characteristic of a multielectrode tube, taken with all electrodes except the cathode connected together.



Diode detector.

diode detector—A diode used in a demodulation, or detection, circuit.

diode gate—An AND gate that uses diodes as switching elements.

diode laser — A PN junction semiconductor electron device which converts direct forward-bias electrical input (pump power) directly into coherent optical output power via a process of stimulated emission in the region near the junction. Called laser diodes, injected lasers, coherent electroluminescence devices, semiconductor lasers.

diode limiter—A circuit employing a diode and used to prevent signal peaks from exceeding a predetermined value.

diode mixer—A diode which mixes incoming radio-frequency and local-oscillator signals to produce an intermediate frequency.

diode peak detector—A diode used in a circuit to indicate when audio peaks exceed a predetermined value.

diode-pentode — A vacuum tube having a diode and a pentode combined in the same envelope.

diode rectification—The conversion of an alternating current into a unidirectional current by means of a two-element device such as a crystal, vacuum tube, etc.

diode switch—A diode in which positive and negative biasing voltages (with respect to the cathode) are applied in succession to the anode in order to pass and block, respectively, other applied waveforms within certain voltage limits. In this way, the diode acts as a switch.

diode transistor logic — Abbreviated DTL. A logic circuit that uses diodes at the input to perform the electronic logic function that activates the circuits transistor output. In monolithic circuits, the DTL diodes are a positive level logic AND function or a negative level OR function. The output transistor acts as an inverter to result in the circuit becoming a positive NAND or a negative NOR function.

diode-triode—A vacuum tube having a diode and triode combined in the same envelope.

diopter—The unit of optical measurement which expresses the refractive power of a lens or prism.

dip—1. A drop in the plate current of a class-C amplifier as its tuned circuits are being adjusted to resonance. 2. The angle between the direction of the earth's magnetic field and the horizontal as measured in a vertical plane.

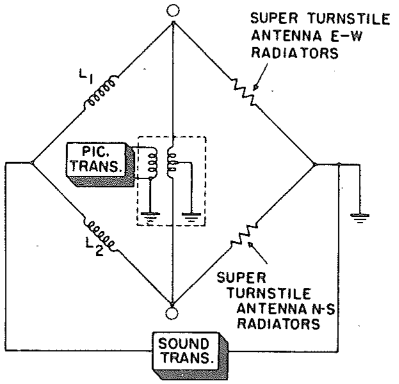
dip coating—1. A method of applying an insulating coating to a conductor by passing it through an applicator containing the insulating medium in liquid form. The insulation is then sized and passed through ovens to solidify. 2. The insulation so applied.

dip encapsulation — A type of conformal coating—An embedding process in which the insulating material is applied by immersion and without the use of an outer container. The coating conforms generally with the contour of the embedding part or assembly.

diplexer—A coupling unit which allows more than one transmitter to operate together on the same antenna.

diplex operation—The simultaneous transmission or reception of two messages from a single antenna or on a single carrier.

diplex radio transmission — Simultaneous



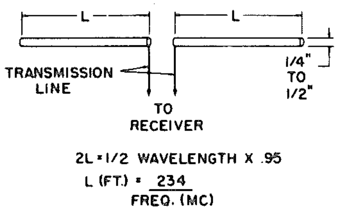
SUPER TURNSTILE ANTENNA E-W RADIATORS
L1
L1
PIC. TRANS.
L2
L2
SUPER TURNSTILE ANTENNA N-S RADIATORS
SOUND TRANS.

Diplexer circuit.

transmission of two signals by using a common carrier wave.

diplex reception—The simultaneous reception of two signals having some feature in common—i.e., a single receiving antenna or a single carrier frequency.

dipole—1. *See* Dipole Antenna. 2. A molecule which has an electric moment. For a molecule to be a dipole, the effective center of the positive charges must be at a different point from the center of the negative charges.



Dipole antenna.

dipole antenna—Also called dipole. A straight radiator usually fed in the center. Maximum radiation is produced in the plane normal to its axis. The length specified is the overall length.

dipole disc feed—An antenna, consisting of a dipole near a disc, used to reflect energy to the disc.

dipping — The process of impregnating or coating insulating materials or windings by the simple method of immersion in the liquid insulating material. A step in the process of treating insulating materials or electrical components by immersion in a liquid insulation, followed by draining and curing to provide increased electrical and mechanical protection.

dip soldering—The process of soldering component leads, terminals, and hardware to the conductive pattern on the "bottom" of a printed-circuit board by dipping that side into molten solder or floating it on the surface.

direct-acting recording instrument—An instrument in which the marking device is mechanically connected to or directly operated by the primary detector.

direct capacitance—The capacitance between two conductors excluding stray capacitance that may exist between the two conductors and other conducting elements.

direct-coupled amplifier — A direct-current amplifier in which the plate of one stage is coupled to the grid of the next stage by a direct connection or a low-value resistor.

direct coupling—The association of two or more circuits by means of an inductance, a resistance, a wire or a combination of these so that both direct and alternating currents can be coupled.

direct current—Abbreviated dc. An essentially constant-value current that flows in only one direction.

direct-current amplifier—Also called d-c amplifier. An amplifier capable of boosting d-c voltages. Resistive coupling only is generally employed between stages, but sometimes will be combined with other forms.

direct-current erasing head—A head which uses direct current in magnetic recording to produce the magnetic field required for erasure. Direct-current erasing is achieved by subjecting the medium to a unidirectional field. Such a medium is therefore in a different magnetic state than one erased by alternating current.

direct-current generator — A rotating machine that changes mechanical into electrical energy in the form of direct current. This is accomplished by commutating bars on the armature. The bars make contact with stationary brushes from which the direct-current is taken.

direct-current restorer — The means by which a direct current or low-frequency component is reinserted after transmission. Used in a circuit incapable of transmitting slow variations, but capable of transmitting components of higher frequency.

direct-current transmission—Of television, that form of transmission in which a fixed setting of the controls makes any instantaneous value of signal correspond to the same value of brightness at all times.

direct digital control — Time sharing, or multiplexing, of a computer among many controlled loops.

direct-drive torque motor—A servoactuator which can be directly attached to the load it is to drive. It converts electrical signals directly into sufficient torque to maintain the desired accuracy in a positioning or speed control system.

direct electromotive force—A unidirectional electromotive force in which the changes in values are either zero or so small that they may be neglected.

direct grid bias—The d-c component of grid bias (voltage). Commonly called grid bias.

direct-insert subroutine—*See* Open Subroutine.

direction—The position of one point in space with respect to another.

directional antenna—An antenna which radiates radio waves more effectively in some directions than in others. (The term is usually applied to an antenna the directivity of which is larger than that of a half-wave dipole.)

directional beam—An electromagnetic wave that is concentrated in a given direction.

directional coupler—A junction consisting of two waveguides coupled together in such a manner that a traveling wave in either guide will induce a traveling wave in the same direction in the other guide.

directional filter — A filter used to separate the two frequency ranges in a carrier system where one range of frequencies is used for transmission in one direction and another range of frequencies for transmission in the opposite direction. Also called directional separation filter.

directional gain—*See* Directivity Index.

directional homing—The procedure of following a path in such a way that the target is maintained at a constant relative bearing.

directional hydrophone—A hydrophone having a response that varies significantly with the direction of incidence of sound.

directional lobe—*See* Lobe.

directional microphone—A microphone the response of which varies significantly with the direction of sound. (*Also see* Unidirectional, Bidirectional, *and* Semidirectional Microphone.)

directional pattern—Also called radiation pattern. A graphical representation of the radiation or reception of an antenna as a function of direction. Cross sections are frequently given as vertical and horizontal planes, and principal electric and magnetic polarization planes.

directional power relay — A device which functions on a desired value of power flow in a given direction, or upon reverse power resulting from arcback in the anode or cathode circuits of a power rectifier.

directional relay—A relay which functions in conformance with the direction of power, voltage, current, pulse rotation, etc. *Also see* Polarized Relay.

directional separation filter—*See* Directional Filter.

direction angle—The angle between the antenna base line and a line connecting the center of the base line with the target.

direction cosine — The cosine of the angle between the base line and the line from the center of the base line to the target.

direction finder — Abbreviated DF. Also called radio compass. Apparatus for receiving radio signals and taking their bearings in order to determine their point of origin.

direction finding—The principle and practice of determining a bearing by radio means, using a discriminating antenna system and a radio receiver so that the direction of an arriving wave, and ostensibly the direction or bearing of a distant transmitter, can be determined.

direction of lay—The lateral direction in which strands or the elements of a cable are wound over the top of the cable. Expressed as right- or left-hand lay, viewed as they recede from the observer.

direction of polarization—For a linearly polarized wave, the direction of the electrostatic field.

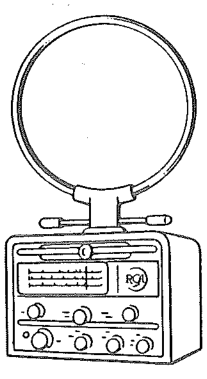
direction of propagation—At any point in a homogeneous, isotropic medium, the direction of the time-average energy flow. In a uniform waveguide, the direction of propagation is often taken along the axis. In a uniform lossless waveguide, the direction of propagation at every point is parallel to the axis and in the direction of time-average energy flow.

direction rectifier — A rectifier which supplies a direct-current voltage, the magnitude and polarity of which are determined by the magnitude and relative polarity of an alternating-current selsyn error voltage.

directive gain—In a given direction, 4π times the ratio of the radiation intensity to the total power radiated by the antenna.

directivity diagram of an antenna — The graphical representation of the gain of an antenna in the different directions of space.

directivity factor—1. In acoustics, the directivity factor is equivalent to directivity, as applied to an antenna. 2. Of a transducer used for sound emission, the ratio of the intensity of the radiated sound at a remote point in a free field on the principal axis to the average intensity of the sound transmitted through a sphere passing through the remote point and concentric with the transducer. 3. Of a transducer used for sound reception, the ratio of the square of the electromotive force produced in response to sound waves arriving in a direction parallel to the principal axis of the transducer to the mean square of the electromotive force that would be produced if sound waves having the same frequency and mean square pressure were arriving at the transducer simul-



Direction finder.

taneously from all directions with random phase. The frequency should be specified in both cases.

directivity index—Also called directional gain. A measure of the directional properties of a transducer. It is the ratio, in decibels, of the average intensity or response over the whole sphere surrounding the projector or hydrophone to the intensity or response on the acoustic axis.

directivity of a directional coupler—Ratio of the power measured at the forward-wave sampling terminals with only a forward wave present in the transmission line, to the power measured at the same terminals when the forward wave reverses direction. This ratio is usually expressed in db and would be infinite for a perfect coupler.

directivity of an antenna—The ratio of the maximum field intensity to the average field intensity at a given distance, implying a maximum value.

directivity signal—A spurious signal present in the output of any coupler because its directivity is not infinite.

direct light—Light from a luminous object such as the sun or an incandescent lamp, as opposed to reflected light.

directly grounded—*See* Solidly Grounded.

directly heated cathode—A wire, or filament, designed to emit the electrons that flow from cathode to plate. This is done by passing a current through the filament; the current heats the filament to the point where electrons are emitted. In an indirectly-heated cathode, the hot filament raises the temperature of a sleeve around the filament; the sleeve then becomes the electron emitter.

director—1. A parasitic antenna element located in the general direction of the major lobe of radiation for the purpose of increasing the radiation in that direction. 2. Equipment in common-carrier telegraph-message switching systems, used to make cross-office selection and connection from an input-line to an output-line equipment in accordance with addresses in the message. 3. A telephone switch which translates the digits dialed into the directing digits actually used to switch the call. 4. Electromechanical equipment which is used to track a moving target in azimuth and angular height, and which, with the addition of other necessary information from an outside source such as a radar set or a range finder, continuously computes firing data and transmits them to the guns.

direct pickup—Transmission of television images without resorting to an intermediate magnetic or photographic recording.

direct piezoelectricity—A name sometimes given to the piezoelectric effect in which an electric charge is developed on a crystal by the application of mechanical stress.

direct-radiator speaker—A speaker in which the radiating element acts directly on the air instead of relying on any other element such as a horn.

direct recording—The production of a visible record without subsequent processing, in response to received signals.

direct-recording magnetic tape—A method of recording using a high-frequency bias in which the electrical input signal is applied to the recording head without alteration.

direct resistance-coupled amplifier—An amplifier in which the plate of one stage is connected either directly or through a resistor to the control grid of the next stage, with the plate-load resistor being common to both stages. Used to amplify small changes in direct current.

direct scanning—In this method, the entire subject is illuminated continuously but the television camera views only one portion of it at a time.

direct sound wave—A wave in an enclosure emitted from a source prior to the time it has undergone its first reflection from a boundary of the enclosure. Frequently a sound wave is said to be direct if it contains reflections that have occurred from surfaces within about 0.05 second after the sound was first emitted.

direct voltage—Also called d-c voltage. A voltage that forces electrons to move through a circuit in the same direction and thereby produce a direct current.

direct wave—A wave that is propagated directly through space, as opposed to one that is reflected from the sky or ground.

direct Wiedemann effect—*See* Wiedemann Effect.

direct-wire circuit—A supervised protective signaling circuit usually consisting of one metallic conductor and a ground return and having signal-receiving equipment responsive to either an increase or a decrease in current.

direct writing recorder—A strip-chart recorder which produces a readable record without further processing.

disc—1. A phonograph record. 2. The blank used in a recorder.

disc capacitor—A small disc-shaped capacitor with a ceramic dielectric, generally used for bypassing or for temperature compensation in tuned circuits.

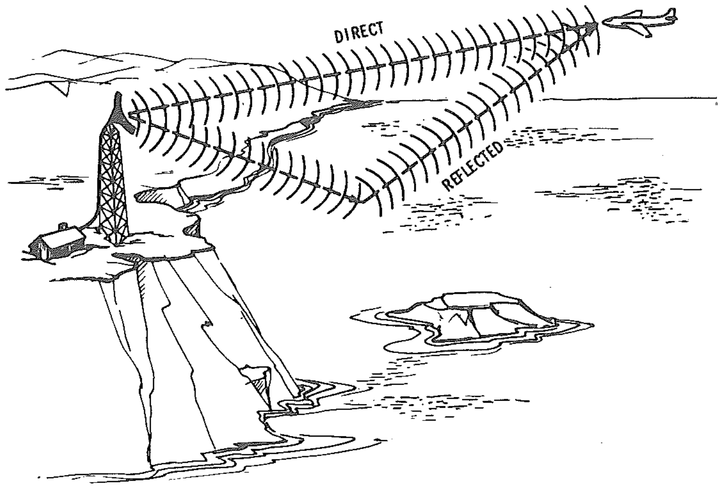
disc files—A type of storage medium consisting of numbers of discs that rotate; each disc has a special coating for retaining stored information.

disc generator—A capacitive-charge type of voltage generator.

discharge—1. In a storage battery, the conversion of chemical energy into electric energy. 2. The release of energy stored in a capacitor when a circuit is connected between its terminals.

discharge breakdown—Breakdown of a material as a result of degradation due to gas discharges.

discharge key—A device for switching a capacitor suddenly from a charging circuit to a load through which it can discharge.



Direct waves.

discharge lamp—A lamp containing a low-pressure gas or vapor which ionizes and emits light when an electric discharge is passed through it. Fluorescent materials are sometimes used on the inside of the glass envelope to increase the illumination, as in an ordinary fluorescent lamp.

discharge rate—The amount of current a battery will deliver over a given period of time. A slower discharge rate generally results in more efficient use of a battery.

discharge tube—A tube containing a low-pressure gas which passes a current whenever sufficient voltage is applied.

discone antenna—A special form of biconical antenna in which the vertex angle of one cone is 180°.

disconnect—1. To break an electric circuit. 2. To remove the power from an electrical device (colloquially, "to unplug the device"). 3. Also called release. To disengage the apparatus used in a connection and to restore it to its ready condition when not in use.

disconnecting means—A device whereby the current-carrying conductors of a circuit can be disconnected from their source of supply.

disconnect switch (motor circuit switch)—A switch intended for use in a motor branch circuit. It is rated in horsepower, and is capable of interrupting the maximum operating overload current of a motor of the same rating at the rated voltage.

disc pack—A set of magnetic discs that can be removed from a disc storage as one unit.

disc recorder—A recording device in which the sounds are mechanically impressed onto a disc—as opposed to a tape recorder, which impresses the sound magnetically on a tape.

discrete component—A component which has been fabricated prior to its installation (e.g., resistors, capacitors, diodes, and transistors).

discrete part—A separately packaged single circuit element supplying one fundamental property as a lumped characteristic in a given application. Examples: resistor, transistor, diode.

discrete sampling—The lengthening of individual samples so that the sampling process does not deteriorate the intelligence frequency response of the channel.

discrete thin-film component—An individually packaged electronic component having one or more thin films serving as resistive, conductive, and/or insulating elements. Resistors and potentiometers having thin-film metallic resistance elements are examples.

discrimination—1. The difference between losses at specified frequencies, with the system or transducer terminated in specified impedances. 2. In a frequency-modulated system, the detection or demodulation of the imposed variations in the frequency of the carriers. 3. In a tuned circuit, the degree of rejection of unwanted signals.

discriminator—1. A device in which amplitude variations are derived in response to frequency or phase variations. 2. Part of a receiver circuit which removes the desired signal from an incoming frequency-modulated carrier wave by changing modulations in terms of frequency variations into amplitude variations. 3. A facsimile auxiliary device between the radio receiver and the recorder which converts an audio-frequency shift facsimile signal to an amplitude-modulated facsimile signal. 4. A circuit, the output voltage of which varies in amplitude and polarity according to the frequency of the applied signal. It is used as a detector in a frequency-modulated receiver.

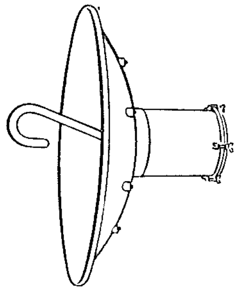
discriminator transformer—A transformer used in f-m receivers to convert frequency changes directly to a-f signals.

discriminator tuning unit—A device which tunes the discriminator to a particular subcarrier.

disc-seal tube—Also called lighthouse tube or megatron. An electron tube with disc-shaped electrodes arranged in closely spaced parallel layers, to give a low interelectrode capacitance along with a high power output in the uhf region.

disc storage—1. A storage device that uses magnetic recording on flat rotating discs. 2. The storage of data on the surface of magnetic discs.

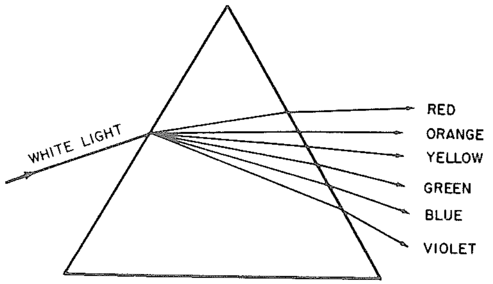
dish—A microwave antenna, usually shaped like a parabola, which reflects the radio energy leaving or entering the system.



Dish antenna.

dislocation—In a crystal, a region in which the atoms are not arranged in the perfect crystal-lattice structure.

dispatcher—In a digital computer, the section which transfers the "words" to their proper destinations.



Dispersion by a prism.

dispersion — 1. Separation of a wave into its component frequencies. 2. Scattering of a microwave beam as it strikes an obstruction. 3. The property of an optical material which causes some wavelengths of light to be transmited through the material at different velocities, and the velocity is a function of the wavelength. (This causes each wavelength of light to have a different refractive index.) 4. In a magnetostrictive delay line, the variation of a delay as a function of frequency. 5. The frequency difference that can be analyzed in one sweep by a spectrum analyzer. Dispersion can be considered as that frequency width over which sampling can be performed, and is always equal to or less than the frequency range.

dispersive medium—A medium in which the phase velocity of a wave is related to the frequency.

displacement — The vector quantity representing change of position of a particle.

displacement current—A current which exists in addition to ordinary conduction current in a-c circuits. It is proportional to the rate of change of the electric field. The current at right angles to the direction of propagation determined by the rate at which the field energy changes.

displacement of porches—The difference in level between the front and back porch of a television signal.

displacement transducer—A device which converts mechanical energy into electrical energy, usually by the movement of a rod or an armature. The amount of output voltage is determined by the amount the rod or armature is moved.

display—Visual presentation of a received signal on a cathode-ray tube.

display loss—*See* Visibility Factor.

display modes—Each display mode, such as vector, increment, character, point, vector continue, or short vector specifies the manner in which points are to be displayed on the screen.

display primaries—Also called receiver primaries. The red, green, and blue colors produced by a color television receiver and mixed in proper proportions to produce other colors.

display unit — A device used to provide a visual representation of data.

display window—The width of the portion of the frequency spectrum presented on panoramic presentation, expressed in frequency units, usually megahertz.

disruptive discharge — The sudden, large current through an insulating medium when electrostatic stress ruptures the medium and thus destroys its insulating ability.

dissector—In optical character recognition, a mechanical or electronic transducer that sequentially detects the level of light in different areas of a completely illuminated sample space.

dissector tube—A camera tube having a continuous photocathode on which a photoelectric-emission pattern is formed. Scanning is done by moving the electron optical image of the pattern over an aperture. (*Also see* Image Dissector.)

dissipation—Loss of electrical energy as heat.

dissipation constant—A constant of proportionality between the power dissipated and the resultant temperature rise in a thermistor at a specified temperature.

dissipation factor—Symbolized by D. Ratio between the permittivity and conductivity of a dielectric. The reciprocal of the dissipation factor is the storage factor, sometimes called the quality factor. Abbreviated DF.

dissonance—The formation of maxima and minima by the superposition of two sets of interference fringes from light of two different wavelengths.

dissymmetrical transducer—Also called dissymmetrical network. A transducer with unequal input and output image impedances.

dissymmetrical network—*See* Dissymmetrical Transducer.

distance mark—Also called range mark. A mark which indicates, on a cathode-ray screen, the distance from the radar set to a target.

distance-measuring equipment — Abbreviated DME. A radio navigational aid for determining the distance from a transponder beacon by measuring the time of transmission to and from it.

distance protection—The effect of a device operative within a predetermined electrical distance on the protected circuit to cause and maintain an interruption of power in a faulty circuit.

distance relay—1. A protective relay, the operation of which is a function of the distance between the relay and the point of fault. 2. A device which functions when the circuit admittance, impedance, or reactance increases or decreases beyond predetermined limits.

distance resolution—The ability of a radar to differentiate targets solely by distance measurement. Generally expressed as the minimum distance the targets can be separated and still be distinguishable.

distortion — An undesired change in the waveform of the original signal, resulting in unfaithful reproduction of audio or video signals. Distortion is classified as nonlinear, frequency, or phase, depending on how the waveform is affected.

distortion factor of a wave—The ratio of the effective value of the residue after the elimination of the fundamental to the effective value of the original wave.

distortion meter — An instrument which measures the deviation of a complex wave from a pure sine wave.

distortion tolerance — Of a telegraph receiver, the maximum signal distortion which can be tolerated without error in reception.

distress frequency—A frequency reserved for distress calls, by international agreement. It is 500 kHz for ships at sea and aircraft over the sea.

distributed—Spread out over an electrically significant length, area, or time.

distributed capacitance — Also called self-capacitance. Any capacitance not concentrated within a capacitor, such as the capacitance between the turns in a coil or choke, or between adjacent conductors of a circuit.

distributed constants—Constants such as resistance, inductance, or capacitance that exist along the entire length or area of a circuit, instead of being concentrated within circuit components.

distributed inductance — The inductance along the entire length of a conductor, as distinguished from the inductance concentrated within a coil.

distributed network—An electrical-electronic device which for proper operation depends on physical size in comparison to a wavelength and physical configuration.

distributed parameter network—A network in which the parameters of resistance, capacitance, and inductance cannot be taken as being concentrated at any one point in space. Rather, the network must be described in terms of its magnetic and electric fields and the quantities related to the distributed constants of the network.

distributed pole—A motor has distributed poles when its stator or field windings are distributed in a series of slots located within the arc of the pole.

distributing amplifier—An amplifier, either radio-frequency or audio-frequency, having one input and two or more isolated outputs.

distributing cable—*See* Distribution Cable.

distributing frame—A structure for terminating permanent wires of a central office, private branch exchange, or private exchange, and for permitting the easy change of connections between them by means of cross-connecting wires.

distributing terminal assembly — A frame situated between each pair of selector bays to provide terminal facilities for the selector bank wiring and facilities for cross connection to trunks running to succeeding switches.

distribution—Also called frequency distribution. The number of occurrences of the particular values of a variable as a function of those values.

distribution amplifier—A power amplifier designed to energize a speech, music, or antenna distribution system. Its output impedance is sufficiently low that changes in the load do not appreciably affect the output voltage.

distribution cable—1. Also called distributing cable. A cable extended from a feeder cable for the purpose of providing service to a specific area. 2. In a system, the transmission cable from the distribution amplifier to the drop cable.

distribution center—In an alternating-current power system, the point at which control and rotating equipment is installed.

distribution coefficients — Equal-powered tristimulus values of monochromatic radiations.

distribution switchboard—A power switchboard used for the distribution of electrical energy at the voltage common for each distribution within a building.

distributor—1. *See* Memory Register. 2. The electronic circuitry which acts as an intermediate link between the accumulator and drum storage.

disturbance — An irregular phenomenon which interferes with the interchange of intelligence during transmission of a signal.

disturbed-one output—A "one" output of a magnetic core to which partial-write pulses have been applied since that core was last selected for writing.

disturbed-zero output—A "zero" output of a magnetic core to which partial-write pulses have been applied since that core was last selected for reading.

dither — An oscillation introduced for the purpose of overcoming the effects of friction, hysteresis, or clogging.

dithering — The application of intermittent or periodic acceleration forces sufficient to minimize the effect of static friction with a transducer, without introducing other errors.

divergence loss—The part of the transmission loss that is caused by the spreading of sound energy.

diverging lens—A lens that is thinner in the center than at the edges. Such a lens causes light passing through to spread out, or diverge.

diversity—A form of transmission using several modes, usually in space or in time, to compensate for fading or outages in any one of the modes. In the space diversity system, the same signal is sent simultaneously over several different transmission paths, which are separated enough so that independent propagation conditions can be expected. With time diversity, the same path may be used, but the signal is transmitted more than once, at different times. There are other forms of diversity, using different frequencies or different polarizations to provide the separate transmission modes.

diversity gain—The gain in reception as a result of the use of two or more receiving antennas.

diversity reception—A method of minimizing the effects of fading during reception of a radio signal. This is done by combining and/or selecting two or more sources of received-signal energy which carry the same intelligence but differ in strength or signal-to-noise ratio in order to produce a usable signal.

diverter pole generator — A compound-wound direct-current generator with the series winding of the diverter pole opposing the flux generated by the shunt-wound main pole; provides a close voltage regulation.

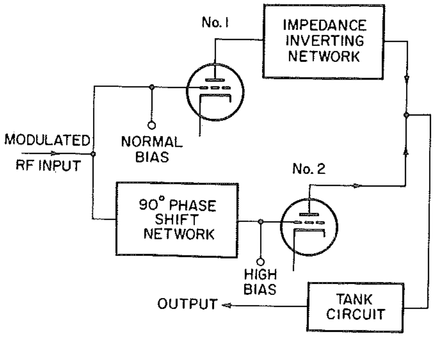
divided-carrier modulation—The process by which two signals are added so that they can modulate two carriers of the same frequency but 90° out of phase. The resultant signal will have the same frequency as the carriers, but its amplitude and phase will vary in step with the variations in amplitude of the two modulating signals.

divider—*See* Frequency Divider.

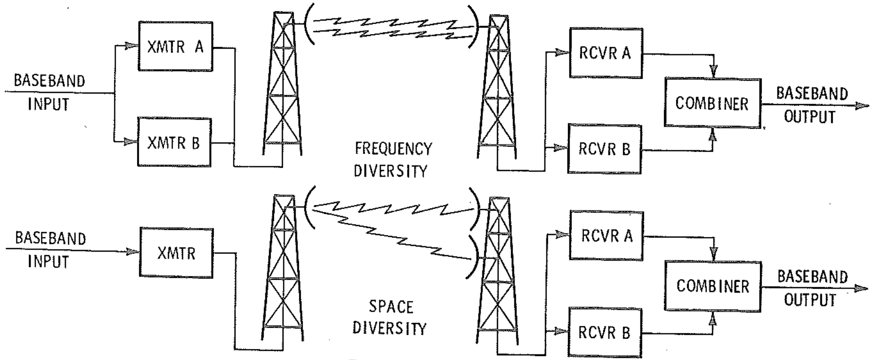
dividing network—Also called speaker dividing network and crossover network. A frequency-selective network which divides the audio-frequency spectrum into two or more parts to be fed to separate devices such as amplifiers or speakers.

D layer—The lowest ionospheric layer. Its intensity is proportional to the height of the sun and is greatest at noon. Waves below approximately 3 MHz are absorbed by the D layer when it is present. High-angle radiation may penetrate the D layer and be reflected by the E layer.

Doherty amplifier—A radio-frequency linear power amplifier divided into two sections, the inputs and outputs of which are connected by quarter-wave (90°) networks. As long as the input-signal voltage is less than half the maximum amplitude, section No. 2 is inoperative and section No. 1 delivers all the power to the load. The load presents twice the optimum impedance required for maximum output. At one-half the maximum input, section No. 1 is operating at peak efficiency but is beginning to saturate. Above this level, section No. 2 comes into operation and decreases the impedance presented to section No. 1. As a result, section No. 2 delivers more and more power to the load until, at maximum signal input, both sections are operating at peak efficiency and each section is delivering one-half the total output power.



Doherty amplifier.



Diversity reception.

dolly—A wheeled platform on which a television camera or other apparatus is mounted to give it wider mobility.

domain—In magnetic theory, that region of a magnetic material in which the spontaneous magnetization is all in one direction. In conventional magnetic-tape coatings, this corresponds to one oxide particle.

domestic induction heater—A home cooking utensil which is heated by induced currents within it. The unit contains a primary inductor, with the utensil itself acting as the secondary.

dominant mode — Also called fundamental mode or principal mode. In waveguide transmission, the mode with the lowest cutoff frequency. Designations for this mode are $TE_{0,1}$ and $TE_{1,1}$ for rectangular and circular wave guides, respectively.

dominant wave—The guided wave which has the lowest cutoff frequency. It is the only wave which will carry energy when the excitation frequency is between the lowest and the next higher cutoff.

dominant wavelength of a color—The predominant wavelength of light in a color.

donor—Also called donor impurity. An impurity atom which tends to give up an electron and thereby affects the electrical conductivity of a crystal. Used to produce N-type semiconductors.

donor impurity—*See* Donor.

donut—*See* Land.

doorknob tube—So called because of its shape. It is a vacuum tube designed for uhf transmiter circuits. It has a low electron-transit time and low interlectrode capacitance because of the close spacing and small size, respectively, of its electrodes.

dopant—An impurity added to a semiconductor to improve its electrical conductivity.

doped junction — A semiconductor junction produced by the addition of an impurity to the melt during crystal growth.

doping—Adding impurities to change the resistivity of semiconductors in order to make N- or P-types.

doping agent—An impurity element added to semiconductor materials used in crystal diodes and transistors. Common doping agents for germanium and silicon include aluminum, antimony, arsenic, gallium, and indium.

doping compensation—The addition of donor impurities to a P-type semiconductor or of acceptor impurities to an N-type semiconductor.

Doppler cabinet—A speaker cabinet in which either the speaker or a baffle board is rotated or moved to change the length of the sound path cyclically and thereby produce a vibrato effect mechanically.

Doppler effect—The observed change of frequency of a wave caused by a time rate of change of the effective distance traveled by the wave between the source and the point of observation. As the distance between a source of constant vibration and an observer diminishes or increases, the received frequencies are greater or less.

Doppler radar—A radar unit that measures the velocity of a moving object by the shift in carrier frequency of the returned signal. The shift is proportionate to the velocity of the object as it approaches or recedes.

Doppler *ranging* (doran)—A c-w trajectory-measuring system which utilizes the Doppler shift to measure the distance between a transmitter, missile, transponder, and several receiving stations. From these measurements trajectory data are computed. In contrast to a similar system, doran circumvents the necessity of continuously recording the Doppler signal by performing the distance measurements with four different frequencies simultaneously.

Doppler shift—The change in frequency of a wave reaching an observer or a system, caused by a change in distance or range between the source and the observer or the system during the interval of reception. It is due to the Doppler effect.

dosage meter—*See* Dosimeter *and* Intensitometer.

dosimeter—Also called intensitometer or dosage meter. An instrument that measures the amount of exposure to nuclear or X-ray radiation utilizing the ability of such radiation to produce ionization of a gas.

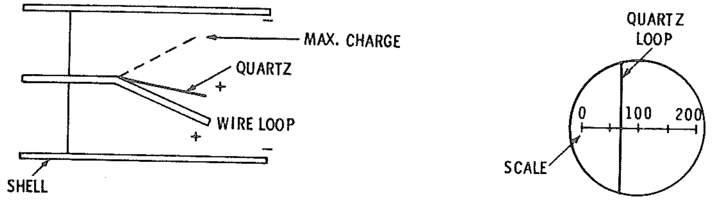
dot—*See* Button.

dot cycle—One cycle of a periodic alternation between two signaling conditions, each condition having unit duration. Thus, two-condition signaling consists of a dot, or marking element, followed by a spacing element.

dot encapsulation — A packaging process in which cylindrical components are inserted into a perforated wafer to form a solid block with interconnecting conductors on both surfaces joining the components.

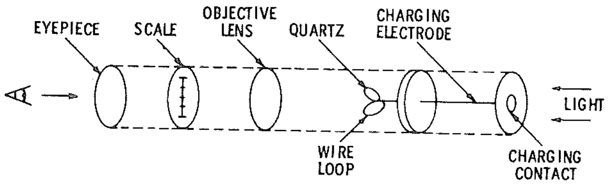
dot generator—An instrument used in servicing color television receivers. It produces a pattern of white dots so that convergence adjustments can be made on the picture tube.

dot pattern—Small dots of light produced on the screen of a color picture tube by the signal from a dot generator. If overall beam convergence has been obtained, the three color-dot patterns will merge into one white-dot pattern.



Expanded view of dosage indicator.

Dosage scale.



Dosimeter viewer.

Pocket dosimeter.

dot sequential—Pertaining to the association of the primary colors in sequence with successive picture elements of a color television system. (Examples: dot-sequential pickup, dot-sequential display, dot-sequential system, dot-sequential transmission.)

double armature—An armature having two windings and commutators but only one core.

double-base diode—*See* Unijunction Transistor.

double-base junction transistor — Also called tetrode junction transistor. Essentially a junction triode transistor with two base connections on opposite sides of the central region of the transistor.

double-beam cathode-ray tube—A cathode-ray tube having two electron beams capable of producing on the screen two independent traces that may overlap. The beams may be produced by splitting the beam of one gun or by using two guns.

double-bounce calibration — A method of calibration used to determine the zero set error by using round-trip echoes. The correct range is the difference between the first and second echoes.

double-break contacts—A set of contacts in which one contact is normally closed and makes simultaneous connection with two other contacts.

double-break switch—A switch which opens the connected circuit at two points.

double bridge—*See* Kelvin Bridge.

double-button carbon microphone — Also called differential microphone. A microphone with two carbon-resistance elements or buttons, one on each side of a central diaphragm. They are connected in parallel to the current source in order to give twice the resistance change obtainable with a single button.

double-checkerboard pattern — *See* Worst-Case Noise Pattern.

double-current generator — A machine which supplies both direct and alternating current from the same armature winding.

double-diffused epitaxial mesa transistor —*See* Epitaxial-Growth Mesa Transistor.

double-diffused transistor—A transistor in which two PN junctions are formed in the semiconductor wafer by gaseous diffusion of both P-type and N-type impurities. An intrinsic region can also be formed.

double diode — Also called duodiode. A vacuum tube or semiconductor having two diodes in the same envelope.

double-diode limiter—A type of limiter used to remove all the positive signals from a combination of positive and negative pulses or to remove all the negative signals from such a combination of positive and negative pulses.

double-doped transistor — A transistor formed by growing a crystal and successively adding P- and N-type impurities to the melt while the crystal is being grown.

double emitter follower — *See* Darlington Amplifier.

double image—A television picture consisting of two overlapping images due to reception of the signal over two paths that differ in length so signals arrive at slightly different times.

double-junction photosensitive semiconductor—A semiconductor in which the current flow is controlled by light energy. It consists of three layers of a semiconductor material with electrodes connected to the ends of each.

double-length number—Also called double-precision number. An electronic computer number having twice the normal number of digits.

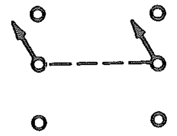
double local oscillator—An oscillator mixing system which generates two r-f signals accurately spaced a few hundred hertz apart and mixes these signals to give the difference frequency which is used as the reference. This equipment is used in an interferometer system to obtain a detectable signal containing the phase information of an antenna pair, and the reference signal to allow removal of the phase data for use.

double-make contacts—A set of contacts in which one contact is normally open and makes simultaneous connection with two other independent contacts when closed.

double moding — Changing from one frequency to another abruptly and at irregular intervals.

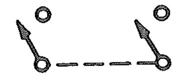
double modulation—The process of modulation in which a carrier wave of one frequency is first modulated by a signal wave, and the resultant wave is then made to modulate a second carrier wave of another frequency.

double pole—A term applied to a contact arrangement to denote that it includes two separate contact forms (i.e., two single-pole contact assemblies).



Double-pole, double-throw switch.

double-pole, double-throw switch—Abbreviated dpdt. A switch that has six terminals and is used to connect one pair of terminals to either of the other two pairs.



Double-pole, single-throw switch.

double-pole, single-throw switch—Abbreviated dpst. A switch that has four terminals and is used to connect or disconnect two pairs of terminals simultaneously.

double-pole switch—A switch that operates simultaneously in two separate electric circuits or in both lines of a single circuit.

double-precision arithmetic—The use of two computer words to represent a number. This is done where it is necessary to obtain greater accuracy than a single word of computer storage will provide.

double-precision number — *See* Double-Length Number.

double-pulsing station — A Loran station that receives two pairs of pulses and emits pulses at two pulse rates.

double pumping—A technique of pumping a laser for a relatively long time to store energy in subthreshold-level excited states, followed immediately by a very brief second pumping in which the threshold condition is exceeded in some region. This triggers laser oscillation throughout the entire active region and produces peak output powers several times larger than normally seen.

double screen—A three-layer screen consisting of a two-layer screen with the additional second long-persistence coating having a different color and different persistence from the first.

double sideband—Amplitude-modulated intelligence which is transmitted at frequencies both above and below the carrier frequency by the audio-frequency value of the intelligence.

double-sideband transmitter — One which transmits not only the carrier frequency, but also the two sidebands resulting from modulation of carrier.

double-spot tuning—Superheterodyne reception of a given station at two different local-oscillator frequencies. The local oscillator is adjusted either above or below the incoming signal frequency by the intermediate-frequency value.

double-stream amplifier — A microwave traveling-wave amplifier in which amplification occurs through interaction of two electron beams having different average velocities.

double-stub tuner—An impedance-matching device consisting of two stubs, usually fixed three-eighths of a wavelength apart, in parallel with the main transmission lines.

double superheterodyne reception — Also called triple detection. The method of reception in which two frequency converters are employed before final detection.

double-surface transistor—A point-contact transistor, the emitter and collector whiskers of which are in contact with opposite sides of the base.

doublet—The output voltage waveform of a delay line under linear operating conditions when the input to the line is a current step function.

doublet antenna—An antenna consisting of two elevated conductors substantially in the same straight line and of substantially equal length, with the power delivered at the center.

double throw—A term applied to a contact arrangement to denote that each contact form included is a breakmate.

double-throw circuit breaker — A circuit breaker by means of which a change in the circuit connections can be obtained by closing either of two sets of contacts.

double-throw switch—A switch which alternately completes a circuit at either of its two extreme positions. It is both normally open and normally closed.

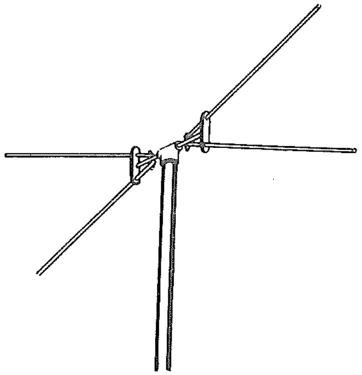
double-track recorder—*See* Dual-Track Recorder.

double triode—*See* Duotriode.

doublet trigger—A trigger signal consisting of two pulses spaced by a fixed amount for coding.

double-tuned amplifier — An amplifier in which each stage utilizes coupled circuits having two frequencies of resonance for the purpose of obtaining wider bands than are possible with single tuning.

double-tuned circuit—A circuit in which two circuit elements are available for tuning.



Double-V antenna.

double-V antenna—Also called fan antenna. A modified single dipole which has a higher input impedance and broader bandwidth than an ordinary dipole.

double-winding synchronous generator—A synchronous generator which has two similar windings in phase with one another, mounted on the same magnetic structure but not connected electrically, designed to supply power to two independent external circuits.

doubly-balanced modulator—A modulator circuit in which two Class-A amplifiers are supplied with modulating and carrier signals of equal amplitudes and opposite polarities. Carrier suppression takes place because the two amplifiers share a common plate circuit and only the sidebands appear at the output.

down lead—The wire that connects an antenna to a transmitter or receiver.

down time—The length of time a device is not usable because of a malfunction.

downward modulation — Modulation in which the instantaneous amplitude of the modulated wave is never greater than that of the unmodulated carrier.

dpdt—Abbreviation for double-pole, double-throw switch.

dpst—Abbreviation for double-pole, single-throw switch.

drag angle—A stylus cutting angle of less than 90° to the surface of the record. So called because the stylus drags over the surface instead of digging in. It is the opposite of dig-in angle.

drag cup—A nonmagnetic metal rotated in a magnetic field to generate a torque or voltage proportional to its speed.

drag-cup motor—A small, high-speed, two-phase, alternating-current electric motor having a two-pole, two-phase stator. The rotating element consists only of an extremely light metal cup attached to a shaft rotating on ball bearings. Reversal is accomplished by reversing the connections to one phase. Used in applications requiring quick starting, stopping, and reversal characteristics.

drag magnet—*See* Retarding Magnet.

drain—1. The current taken from a voltage source. 2. In a field-effect transistor, the element that corresponds to the plate of a vacuum tube.

drainage equipment — Equipment used to protect connected circuits from transients produced by the operation of protection equipment.

drain wire—A metallic conductor frequently used in contact with foil-type signal-cable shielding to provide a low-resistance ground return at any point along the shield.

D-region—The region of the ionosphere up to about 90 kilometers above the earth's surface. It is below the E-region.

dress—The exact placement of leads and components in a circuit to minimize or eliminate undesirable feedback and other troubles.

drift—1. Movement of carriers in a semiconductor as voltage is applied. 2. A change in either absolute level or slope of an input-output characteristic. 3. *See* Flutter. 4. *See* Degradation. 5. An undesired change in one of the output parameters of a power supply (voltage, current, frequency, etc.) over a period of time. The change is unrelated to all other variables such as load, line, and environment. Drift is measured over a period of time by keeping all variables (such as line, load, and environment) constant. Specifications usually apply only after a warm-up period. 6. The angular displacement of an aircraft by the wind, generally expressed in degrees. 7. In a d-c amplifier, the change in output with constant input, usually measured in terms of the d-c input signal required to restore normal output; may be called out as microvolts or millivolts per hour. 8. A change in output attributable to any cause.

drift mobility—The average drift velocity of carriers in a semiconductor per unit electric field. In general, the mobilities of electrons and holes are not the same.

drift space — In an electron tube, a region substantially free of alternating fields from external sources, in which relative repositioning of the electrons depends on their velocity distributions and the space-charge forces.

drift speed—Average speed at which electrons or ions progress through a medium.

drift transistor—A type of transistor manufactured with a variable-conductivity base region. Such a base sets up an electric field which speeds up the carriers, thus reducing the transit time and improving high-frequency operation.

drift velocity—Net velocity of charged particles in the direction of the applied field.

drip loop—A loop formed in a transmission line at a point where it enters a building. Condensation of moisture and water that may form on the line will drip off at the loop and thus will not enter the building.

drip-proof motor — A motor in which the ventilating openings are such that foreign matter falling on the motor at any angle not exceeding 15° from the vertical cannot enter the motor either directly or indirectly.

driptight enclosure—An enclosure that is intended to prevent accidental contact with the enclosed apparatus and, in addition, is so constructed as to exclude falling moisture or dirt.

drive—*See* Excitation.

drive belt — A belt used to transmit power from a motor to a driven device.

drive circuit—A circuit, usually a printed-circuit card or an encapsulated module, that converts an input pulse to the appropriate winding excitation sequence to produce one step of the motor shaft.

drive control—*See* Horizontal-Drive Control.

driven element—An antenna element connected directly to the transmission line.

driven sweep—A sweep signal triggered by an incoming signal only.

drive pin—In disc recording, a pin similar to the center pin but located at one side of it and used to prevent a disc record from slipping on the turntable.

drive pulse—A pulsed magnetomotive force applied to a magnetic cell from one or more sources.

driver—1. An electronic circuit which supplies input to another electric circuit. 2. A stage of amplification which precedes the power output stage. 3. In a radar transmitter, a circuit which produces a pulse to be delivered to the control grid of the modulator tube. 4. A unit or stage driving another unit or stage.

driver element—An antenna array element that receives power directly from the transmitter.

driver stage—The amplifier stage preceding the power-output stage.

driving-point admittance—The complex ratio of the alternating current to the applied alternating voltage for an electron tube, network, or other transducer.

driving-point impedance—At any pair of terminals in a network, the driving-point impedance is the ratio of an applied potential difference to the resultant current at these terminals, all terminals being terminated in any specified manner.

driving power—The power supplied to the grid circuit of a tube where the grid swings positive and draws current for part of each cycle of the input signal.

driving-range potential — The voltage difference between the potential of the electrochemically more active anode and the less active protected metal or cathode. One example of driving potential is the electromotive force in a cathodic protection system that causes current between the protected structure (cathode) and the anode. The driving potential decreases as the electrodes become polarized.

driving signal—Television signals that time the scanning at the pickup point. Two kinds of driving signals are usually available from a central sync generator, one composed of pulses at the line frequency and the other of pulses at the field frequency.

driving spring—The spring driving the wipers of a stepping relay.

drone cone — An undriven speaker cone mounted in a bass-reflex enclosure.

droop — The decrease in mean pulse amplitude, expressed as a percentage of the 100% amplitude, at a specified time following the initial attainment of 100% amplitude.

drop bar—A protective device used to ground a high-voltage capacitor when opening a door.

drop bracket transposition—Reversal of the relative positions of two parallel wire conductors while depressing one, so that the crossover is in a vertical plane.

drop cable—In a catv system, the transmission cable from the distribution cable to a dwelling.

drop channel—A type of operation in which one or more channels of a multichannel system are terminated (dropped) at some intermediate point between the end terminals of the system.

drop indicator—An indicator for signaling, consisting of a hinged flap normally held up by a catch. The catch is released by an electromagnet, allowing the flap to drop when a signal is received.

dropout—1. Separate and distinct variations in signal level during reproduction of recorded data, the result of which causes an error in data reduction. 2. Any discrete variation in signal level during the reproduction of magnetic-tape recorded data which results in a data-reduction error.

dropouts—Also called keys. Special images inserted at certain points in the array on a photomask used in the production of monolithic circuits.

drop-out value—The maximum value of current, voltage, or power which will de-energize a previously energized relay. (*Also see* Hold Current *and* Pickup Value.)

dropping resistor—A resistor used to decrease a given voltage by an amount equal to the potential drop across the resistor.

drop repeater—A microwave repeater station equipped for local termination of one or more circuits.

drop wire—A wire suitable for extending an open wire or cable pair from a pole or cable terminal to a building.

drum memory — A rotating cylinder or disc coated with magnetic material so that information can be stored in the form of magnetic spots.

drum recorder—A facsimile recorder in which the record sheet is mounted on a rotating cylinder.

drum speed—The number of revolutions per minute made by the transmitting or receiving drum of a facsimile transmitter or recorder.

drum switch—A switch in which the electrical contacts are made on pins, segments, or surfaces on the periphery of a rotating cylinder or sector, or by the operation of a rotating cam.

drum transmitter—A facsimile transmitter in which the copy is mounted on a rotating cylinder.

drum-type controller—1. A multicircuit timing device, with or without a motor, using a cylindrical carriage into which pins are inserted to program events. 2. A multicircuit timing device intended to be driven from an external rotary power source.

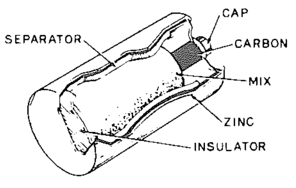
drunkometer—A device measuring the degree of alcoholic intoxication by analyzing the subject's breath.

dry—A condition in which the electrolyte in a cell is immobilized. The electrolyte may be either in the form of a gel or paste or absorbed in the separator material.

dry battery—Two or more dry cells arranged in series, parallel, or series-parallel within a single housing to provide desired voltage and current values.

dry cell—A voltage-generating cell having an immobilized electrolyte. The commonest form has a positive electrode of carbon and a negative electrode of zinc in an electrolyte of sal ammoniac paste.

dry circuit—A circuit in which the open-circuit voltage is .03V or less and the current 200ma or less. (The voltage is most important because at such a low level it is not able to break through most oxides, sulfides, or other films which can build up on contacting surfaces.)



Dry cell.

dry contacts—Contacts which neither break nor make a circuit.

dry-disc rectifier—A rectifier consisting of discs of metal and other materials in contact under pressure. Examples are the copper-oxide and the selenium rectifier.

dry-electrolytic capacitor—An electrolytic capacitor with a paste rather than liquid electrolyte. By eliminating the danger of leakage, the paste electrolyte permits the capacitor to be used in any position.

dry flashover voltage—The voltage at which the air surrounding a clean, dry insulator or shell completely breaks down between electrodes.

dry-reed relay—A relay that consists of one or more capsules containing contact mechanisms that are generally surrounded by an electromagnetic coil for actuation. The capsule consists of a glass tube with a flattened ferromagnetic reed sealed in each end. These reeds, which are separated by an air gap, extend into the tube so as to overlap. When placed in a magnetic field, they are brought together and close a circuit.

dry shelf life—The length of time that a cell can stand without electrolyte before it deteriorates to a point where a specified output cannot be obtained.

dry-type force-air-cooled transformer (class AFA)—A transformer which is not immersed in oil and which derives its cooling by the forced circulation of air.

dry-type self-cooled/forced-air-cooled transformer (class AA/FA)—A transformer which is not immersed in oil, and which has a self-cooled rating with cooling obtained by the forced circulation of air.

dry-type self-cooled transformer (class AA)—A transformer which is cooled by the natural circulation of air and which is not immersed in oil.

dry-type transformer—A transformer which is cooled by the circulation of air and which is not immersed in oil.

dsc—Abbreviation for double silk-covered.

D-scope—A radar display similar to a C-scope except that the blips extend vertically to give a rough estimate of the distance.

"D" service—FAA service pertaining to radio broadcast of meteorological information, advisory messages, and notices to airmen.

DT-cut crystal—A crystal cut to vibrate below 500 kHz.

dual-beam oscilloscope—An oscilloscope in which the cathode-ray tube produces two separate electron beams that may be individually or jointly controlled.

dual capacitor—Two capacitors within a single housing.

dual-channel amplifier—An amplifier which has two channels independent of each other, but similar in design, construction, and output.

dual-diversity receiver—A radio receiver that receives signals from two different receiving antennas and uses whichever signal is the stronger at each instant to offset fading. In one arrangement, two identical radio-frequency systems, each with its own antenna, feed a common audio-frequency channel. In another arrangement, a single receiver is changed over from one antenna to the other by electronic switching at a rate fast enough to prevent loss of intelligibility.

dual-emitter transistor—A passivated PNP silicon planer epitaxial transistor with two emitters; used as a low-level chopper.

dual-frequency induction heater—A type of induction heater in which work coils operating at two different frequencies induce energy, either simultaneously or successively, to material within the heater.

dual-groove record—*See* Cook System.

dual meter—A meter constructed so that two aspects of a circuit may be read simultaneously.

dual modulation—The use of two different types of modulation, each conveying separate intelligence, to modulate a common carrier or subcarrier wave.

dual pickup—*See* Turnover Pickup.

dual trace—A mode of operation in which a single beam in a cathode-ray tube is shared by two signal channels. *Also see* Alternate Mode *and* Chopped Mode.

dual-track recorder—Sometimes called a half-track recorder. Its recording head covers only half the width of the tape, making it possible to record on one half of the tape and then, by turning the reels over, to record on the unused half.

dubbing—In radio broadcasting, the addition of sound to a prerecorded tape or disc.

duct—1. A protective pipe through which conductors or cables are run. 2. In microwave transmission, atmospheric conditions may cause radio waves to follow a narrower path than usual. The narrower path is called a duct. The presence of ducting sometimes causes unusual transmission because the transmission waves do not follow the intended path.

ducting—The trapping of an electromagnetic wave, in a waveguide action, between two layers of the earth's atmosphere, or between a layer of the atmosphere and the earth's surface.

dummy antenna—*See* Artificial Antenna.

dummy instruction—An artificial instruction or address inserted in a list of instructions to a computer solely to fulfill prescribed conditions (such as word length or block length) without affecting the operation.

dummy load—*See* Artificial Load.

dump—1. Also called power dump. To withdraw all power from a computer, either accidentally or intentionally. 2. To transfer all or part of the contents of one section of a digital-computer memory into another section.

dump check—Checking a computer by adding all digits as they are dumped (transferred) to verify the sum to make sure no errors exist as the digits are retransferred.

dumping resistor—A resistor whose function is to discharge a capacitor or network for safety purposes.

duodecal socket—A vacuum-tube socket having 12 pins. Used for cathode-ray tubes.

duodecimal—1. Pertaining to a characteristic or property involving a selection, choice, or condition in which there are 12 possibilities. 2. Pertaining to the numbering system with a radix of 12.

duodiode—Also called dual diode. A vacuum tube or semiconductor having two diodes within the same envelope.

duodiode-pentode—An electron tube containing two diodes and a pentode in the same envelope.

duodiode-triode—An electron tube containing two diodes and a triode in the same envelope.

duolateral coil—*See* Honeycomb Coil.

duopole—An all-pass section with two poles and two zeros.

duotriode—An electron tube containing two triodes in the same envelope. Also called double triode.

duplex—1. The method of operation of a communication circuit in which each end can simultaneously transmit and receive. (Ordinary telephones are duplex. When used on a radio circuit, duplex operation requires two frequencies.) 2. Two-in-one, as two conductors with a common overall insulation or two telegraph transmission channels over one wire.

duplex artificial line—A balancing network simulating the impedance of the real line and distant terminal apparatus; it is employed in a duplex circuit for the purpose of making the receiving device unresponsive to outgoing signal currents.

duplex cable—A cable composed of two insulated stranded conductors twisted together. They may or may not have a common insulating covering.

duplex channel—A communication channel providing simultaneous transmission in both directions.

duplexer—A radar device which, by using the transmitted pulse, automatically switches the antenna from receive to transmit at the proper time.

duplexing assembly (radar)—*See* TR Switch.

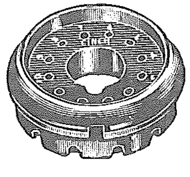
duplex operation—Simultaneous operation of transmitting and receiving apparatus at two locations.

duplex system—A system with two distinct and separate sets of facilities, each of which is capable of assuming the system function while the other assumes a standby status. Usually both sets are identical in nature.

duplex tube—A combination of two vacuum tubes in one envelope.

duplication check—A computer check in which the same operation or program is checked twice to make sure the same result is obtained both times.

duration control—A control for adjusting



Duodecal socket.

the time duration of reduced gain in a sensitivity-time control circuit.

during cycle—The interval while a timer is operating for its present time period.

dust core—A pulverized iron core consisting of extremely fine iron particles mixed with a binding material for use in radio-frequency coils.

dust-ignitionproof motor — A totally enclosed motor, the enclosure of which is designed and constructed in a manner that will exclude ignitable amounts of dust or amounts which might affect the performance rating, and will not permit arcs, sparks, or heat otherwise generated or liberated inside the enclosure to cause ignition of exterior accumulations or atmospheric suspensions of a specific dust on or in the vicinity of the enclosure.

duty cycle—The amount of time a device operates, as opposed to its idle time. Applied to a device that normally runs intermittently rather than continuously.

duty cyclometer—A test meter which gives a direct reading of duty cycle.

duty factor—1. In a carrier composed of regularly recurring pulses, the product of their duration and repetition frequency. 2. Ratio of average to peak power.

duty ratio—In a pulsed system, such as radar, the ratio of average to peak power.

DX—1. Abbreviation for distance. 2. Reception of distant stations.

DX hound—An amateur who specializes in making distant contacts.

dynamic acceleration — Acceleration in a constantly changing magnitude and direction, either simple or complex motion usually called vibration. Also measured in gravity units.

dynamic braking—A system of braking of an electric drive in which the motor is used as a generator, and the kinetic energy of the motor and driven machinery is employed as the actuating means of exerting a retarding force.

dynamic characteristics — Relationship between the instantaneous plate voltage and plate current of a vacuum tube as the voltage applied to the grid is varied.

dynamic check — A check used to ascertain the correct performance of some or all components of equipment or a system under dynamic or operating conditions.

dynamic contact resistance—In a relay, a change in contact electrical resistance due to a variation in contact pressure on mechanically closed contacts.

dynamic convergence—The condition where the three beams of a color picture tube come together at the aperture mask as they are reflected both vertically and horizontally. (*Also see* Vertical Dynamic Convergence *and* Horizontal Dynamic Convergence.)

dynamic decay — In a storage tube, decay caused by an action such as that of ion charging.

dynamic demonstrator—A three-dimensional schematic diagram in which the components of the radio, television receiver, etc., are mounted directly on the diagram.

dynamic deviation — The difference between the ideal output value and the actual output value of a device or circuit when the reference input is changing at a specified constant rate and all other transients have expired.

dynamic equilibrium of an electromagnetic system—1. The tendency of any electromagnetic system to change its configuration so that the flux of magnetic induction will be maximum. 2. The tendency of any two current-carrying circuits to maintain the flux of magnetic induction linking the two at maximum.

dynamic error—An error in a time-varying signal resulting from inadequate dynamic response of a transducer.

dynamic focus—The application of an a-c voltage to the focus electrode of a color picture tube to compensate for the defocusing caused by the flatness of the screen.

dynamic magnetic field—A field the intensity of which is changing and the lines of force of which are expanding or contracting. Such change can be periodic or random. Unlike the static field, the dynamic field can transfer energy from one point to another without relative motion between the points.

dynamic microphone—*See* Moving-Coil Microphone.

dynamic mutual-conductance tube tester—*See* Transconductance Tube Tester.

dynamic noise suppressor—An audio filter the bandpass of which is adjusted automatically to the signal level. At low signal levels filtering is highest, and at high signal levels all filter action is removed.

dynamic output impedance—*See* Output Impedance.

dynamic pickup—*See* Moving-Coil Pickup.

dynamic plate impedance—The internal resistance to the flow of alternating current between the cathode and plate of a tube.

dynamic plate resistance—*See* A-C Plate Resistance.

dynamic printout—In a computer, a printout of data which occurs as one sequential operation during the machine run.

dynamic range—1. The difference, in decibels, between the overload level and the minimum acceptable signal level in a system or transducer. 2. The ratio of the specified maximum signal-level capability of a system or component to its noise or resolution level, usually expressed in decibels.

dynamic regulator—A transmission regulator in which the adjusting mechanism is in self-equilibrium at only one or a few settings and requires control power to maintain it at any other setting.

dynamic reproducer — *See* Moving-Coil Pickup.

dynamic resistance — Incremental resistance

measured over a relatively small portion of the operating characteristic of a device.

dynamic run—Also called dynamic test. The test performed on an instrument to obtain the overall behavior and to establish or corroborate specifications such as frequency response, natural frequency of the device, etc.

dynamic sequential control—A method of operation in which a digital computer can alter instructions or their sequence, as the computation proceeds.

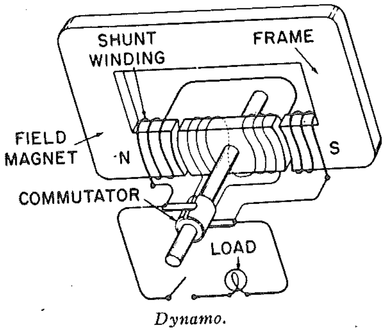
dynamic speaker—*See* Moving-Coil Speaker.

dynamic storage — Stored computer data which remain in motion on the sensing device (i.e., acoustic delay line, magnetic drum, etc.), as opposed to static storage.

dynamic subroutine — In digital-computer programming, a subroutine which involves parameters (such as decimal point position) from which a properly coded subroutine is derived. The computer itself adjusts or generates the subroutine according to the parametric values chosen.

dynamic test—*See* Dynamic Run.

dynamic transfer-characteristic curve — A curve showing the variation in output current as the input current changes.



Dynamo.

dynamo—1. Normally called a generator. A machine that converts mechanical energy into electrical energy by electromagnetic induction. 2. In precise terminology, a generator of direct current—as opposed to an alternator, which generates alternating current.

dynamoelectric—Pertaining to the relationship between mechanical force and electrical energy or vice versa.

dynamometer—1. An instrument in which the force between a fixed and a moving coil provides a measure of current, voltage, or power. 2. Equipment designed to measure the power output of a rotating machine by determining the friction absorbed by a hand brake opposing the rotation.

dynamotor—Also called a rotary converter or synchronous inverter. A rotating device for changing a d-c voltage to another value. It is a combination electric motor and d-c generator with two or more armature windings and a common set of field poles. One armature winding receives the direct current and rotates (thus operating as a motor), while the others generate the required voltage (and thus operate as dynamos or generators).

dynaquad—A germanium PNPN semiconductor switching device which is base-controlled and has three terminals. Its operation is similar to that of a flip-flop circuit or latching relay.

dynatron—*See* Tetrode.

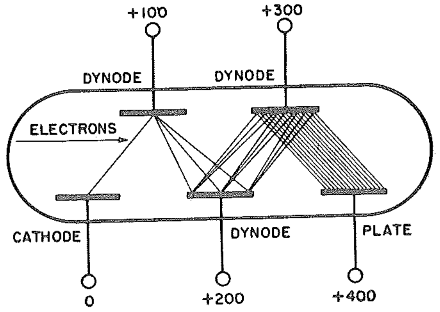
dynatron oscillator — A negative-resistance oscillator with negative resistance derived between the plate and cathode of a screen-grid tube operating such that secondary electrons produced at the plate are attracted to the higher-potential screen grid.

dyne—The force that produces an acceleration of one centimeter per second per second on a one-gram mass.

dyne per square centimeter — The unit of sound pressure. One dyne per square centimeter was originally called a bar in acoustics, but the full expression is used in this field now because the bar is defined differently in other applications. Also called microbar.

dynistor—A nonlinear semiconductor having the characteristics of a small current flow as voltage is applied. As the applied voltage is increased a point is reached at which the current flow suddenly increases radically and will continue at this rate even though the applied voltage is reduced.

dynode—An electrode having the primary function of supplying secondary-electron emission in an electron tube.



Dynode.

E

E—1. Symbol for voltage or emitter. 2. Abbreviation for illumination.

E and M leads—In a signaling system, the output and input leads, respectively.

early-failure period—The period of equipment life, starting immediately after final assembly, during which equipment failures initially occur at a higher than normal rate due to the presence of defective parts and abnormal operating procedures. Also called debugging period, burn-in period, or infant-mortality period.

early-warning radar—A radar which usually scans the sky in all directions, in order to detect approaching enemy planes and/or missiles at distances far enough away that interceptor planes can be in the air to meet their approach before they are near their target.

earphone—Also called receiver. An electroacoustic transducer intended to be placed in or over the ear.

earth—Term used in Great Britain for ground.

earthed—A British term meaning grounded.

earth inductor—*See* Generating Magnetometer.

earth oblateness—The slight departure from a perfect spherical shape of the shape of the earth and the form of its gravity field.

E-bend—*See* E-Plane Bend.

ebiconductivity—Conductivity induced as the result of electron bombardment.

ebmd—Abbreviation for electron-beam mode discharge.

ec—Abbreviation for enamel covered.

eccentric circle—*See* Eccentric Groove.

eccentric groove—Also called eccentric circle. An off-center locked groove for actuating the trip mechanism of an automatic record changer at the end of a recording.

eccentricity—In disc recording, the displacement of the center of the recording-groove spiral with respect to the record center hole.

Eccles-Jordan circuit—A flip-flop circuit consisting of a two-stage, resistance-coupled electron-tube amplifier. Its output is coupled back to its input, two separate conditions of stability being achieved by alternately biasing the two stages beyond cutoff.

ECCM (electronic counter-countermeasures)—Retaliatory tactics used to reduce the effectiveness of electronic countermeasures.

ECDC (abbreviation for ElectroChemical Diffused-Collector transistor)—A PNP transistor in which all the mass of P material is etched off and replaced with metal, which acts as a heat sink. It is suitable for high-current, high-speed core driver and computer-memory applications.

echelon—One of a series of levels of accuracy of calibration, the highest of which is represented by an accepted national standard. There may be auxiliary levels between two successive echelons.

echo—1. In radar, that portion of the energy reflected to the receiver from a target. 2. A wave which has been reflected or otherwise returned with sufficient magnitude and delay to be distinguishable from the directly transmitted wave. 3. In facsimile, a multiple reproduction on the record sheet caused by the arrival of the same original facsimile signal at different times over transmission paths of different lengths. 4. In a radio system, an electronic condition which causes a signal such as a voice signal to be reflected from some point or points in the circuit back to the point of origination of the signal. 5. A delayed repetition (sometimes several rapid repetitions) of the original sound or signal.

echo area—Equivalent echoing area of a radar target (i.e., the relative amount of radar energy the target will reflect).

echo attenuation—In a four-wire (or two-wire) circuit equipped with repeater or multiplex equipment in which the two directions of transmission can be separated from each other, the attenuation of the echo currents (which return to the input of the circuit under consideration) is determined by the ratio of the transmitted power P1 to the echo power received P2.

echo box—Also called phantom target. A device for checking the over-all performance of a radar system. It comprises a resonant cavity which receives a portion of the pulse energy from the transmitter and retransmits it to the receiver as a slowly decaying transient. The time required for this transient response to decay below the minimum detectable level on the radar indicator is known as the ring time and is indicative of the over-all performance of the radar set.

echo chamber—A reverberant room or enclosure used for adding hollow effects or actual echoes to radio or television programs.

echo check—A method of checking the accuracy of transmission of data in which the received data are returned to the sending end for comparison with the original data.

echo depth sounder—*See* Fathometer.

echo depth sounding—A system of determining the ocean depth by producing a sound just below the water's surface and measuring the amount of time before the echo is reflected from the floor of the ocean.

echo intensifier—A device, located at the target, that is used to increase the amplitude of the reflected energy to an abnormal level.

echo matching—Rotating an antenna to a position in which the pulse indications of an echo-splitting radar are equal.

echo ranging—Determination of both direction and distance of an underwater object from a vessel by ultrasonic radiation.

echo sounder—A sounding device used by ships to determine the depth of water. (*Also see* Echo Depth Sounding.)

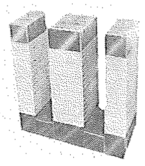
echo splitting—In certain radar equipment, the echo return is split and appears as a double indication on the screen of the radar indicator. This splitting is accomplished by special electronic circuits associated with the antenna lobe switching mechanism. When the two echo indications are of equal height, the target bearing is read from a calibrated scale.

echo suppressor—1. A voice-operated device that is connected to a two-way telephone circuit to attenuate echo currents in one direction caused by telephone currents in the other direction. 2. In navigation, a circuit which desensitizes the equipment for a fixed period after the reception of one pulse, for the purpose of rejecting delayed pulses arriving from indirect reflection.

echo talker—A portion of the transmitted signal returned from a distant point to the transmitting source with sufficient time delay to be received as interference.

ECM (electronic countermeasures)—Methods of jamming or otherwise hindering the operation of enemy electronic equipment.

ECO—Abbreviation for electron-coupled oscillator.



E-core.

E-core—The laminated configuration resembling the capital letter *E* in some transformers and inductive transducers.

eddy-current heating—Synonym for induction heating.

eddy-current loss—The core loss which results when a varying induction produces electromotive forces which cause a current to circulate within a magnetic material.

eddy currents—Also called Foucault currents. Those currents induced in the body of a conducting mass by a variation in magnetic flux.

edge effect—1. *See* Following or Leading White *and* Following or Leading Black. 2. Nonuniformity of electric fields between two parallel plates caused by an outward bulging of electric flux lines at the edges of the plates.

edging—Undesired coloring around the edges of different-colored objects in a color television picture.

Edison base—Standard screw-thread base used for ordinary electric lamps.

Edison distribution system—A three-wire direct-current distribution system, usually 120 to 240 volts, for combined light and power service from a single set of mains.

Edison effect—Also called Richardson effect. The phenomenon wherein electrons emitted from a heated element within a vacuum tube will flow to a second element that is connected to a positive potential.

Edison storage cell—A storage cell having negative plates of iron oxide and positive plates of nickel oxide immersed in an alkaline solution. An open-circuit voltage of 1.2 volts per cell is produced.

E-display—In radar, a rectangular display in which targets appear as blips with distance indicated by the horizontal coordinate and elevation by the vertical coordinate.

EDP—Abbreviation for electronic data processing.

EDP center—*See* Electronic Data Processing Center.

EDPM—Abbreviation for electronic data-processing machine.

eeg—Abbreviation for electroencephalograph.

effective acoustic center—The point from which the spherically divergent sound waves from an acoustic generator appear to diverge. Also called apparent source.

effective actuation time—The sum of the initial actuation time and the contact chatter intervals of a relay following such actuation.

effective ampere—That alternating current which, when flowing through a standard resistance, produces heat at the same average rate as 1 ampere of direct current flowing in the same resistance.

effective antenna length—The length which, when multiplied by the maximum current, will give the same product as the length and uniform current of an elementary electric dipole at the same location, and the same radio field intensity in the direction of maximum radiation.

effective area—The effective area of an antenna in any specified direction is equal to the square of the wavelength multiplied by the power gain (or directive gain) in that direction, divided by 4π.

effective bandwidth—For a bandpass filter, the width of an assumed rectangular bandpass filter having the same transfer ratio at a reference frequency and passing the same mean-square value of a hypothetical current and voltage having even distribution of energy over all frequencies.

effective capacitance—The total capacitance existing between any two given points of an electric circuit.

effective conductivity—The conductance between the opposite parallel faces of a portion of a material having unit length and unit cross section.

effective current—That value of alternating current which will give the same heating effect as the corresponding value of direct current. For sine-wave alternating currents, the effective value is 0.707 times the peak value.

effective cutoff—*See* Effective Cutoff Frequency.

effective cutoff frequency—Also called effective cutoff. The frequency at which the insertion loss of an electric structure between specified terminating impedances exceeds the loss at some reference point in the transmission band.

effective field intensity—Root-mean-square value of the inverse distance fields one mile from the transmitting antenna in all directions horizontally.

effective height—The height of the antenna center of radiation above the effective ground level.

effectively grounded—Grounded through a ground connection of sufficiently low impedance (inherent and/or intentionally added) so that fault grounds which may occur cannot build up voltages that are dangerous to connected equipment.

effective parallel resistance—The resistance leakage considered to be in parallel with a pure dielectric.

effective percentage modulation—For a single, sinusoidal input component, the ratio between the peak value of the fundamental component of the envelope and the direct-current component in the modulated conditions, expressed in percent.

effective radiated power—Antenna input times gain, expressed in watts. If specified for a particular direction, it is the antenna power gain in that direction only.

effective radius of the earth—A value used in place of the geometrical radius to correct the atmospheric refraction when the index of refraction in the atmosphere changes linearly with height. Under conditions of standard refraction, the effective radius is one and one-third the geometrical radius.

effective resistance—1. The average rate of dissipation of electric energy during a cycle divided by the square of the effective current. 2. The equivalent pure d-c resistance which, when substituted for the winding of a motor being checked, will draw the same power. It is also equivalent to the impedance of a circuit having a capacitor connected in parallel with the winding and the capacitor adjusted to unity power factor for the circuit.

effective series resistance—A dropping resistance considered to be in series with an assumed pure capacitance.

effective sound pressure—The root-mean-square value of the instantaneous sound pressure at one point over a complete cycle. The unit is the dyne per square centimeter.

effective speed—The speed (less than rated) which can be sustained over a significant period of time and which reflects slowing effects of control codes, timing codes, error detection, retransmission, tabbing, hand keying, etc.

effective speed of transmission—The average rate over some specified time interval at which information is processed by a transmission facility. Usually expressed as average characters or average bits per unit time. Also called average rate of transmission.

effective thermal resistance—Of a semiconductor device, the effective temperature rise per unit power dissipation of a designated junction above the temperature of a stated external reference point under conditions of thermal equilibrium.

effective value—Also called the rms (root mean square) value. The value of alternating current that will produce the same amount of heat in a resistance as the corresponding value of direct current. The effective value is 0.707 times the peak value.

effective wavelength—The wavelength corresponding to the effective propagation velocity and the observed frequency.

efficiency—1. Ratio of the useful output of a physical quantity which may be stored, transferred, or transformed by a device, to the total input of the device. 2. The ratio of the output power to the input power of a regulated power supply, expressed in percent. In the absence of statements to the contrary, it is assumed to be taken at nominal input and output levels and full load conditions.

efficiency of a source of light—The ratio of the total luminous flux to the total power consumed. In the case of an electric lamp, it is expressed in lumens per watt.

efficiency of rectification—Ratio of direct-current power output to alternating-current power input of a rectifier.

EGO—Acronym for Eccentric orbit Geophysical Observatory.

ehf—Abbreviation for extremely high frequency.

E-H tee—A waveguide junction composed of a combination of E and H plane tee junctions which intersect the main guide at a common point.

E-H tuner—An E-H tee having two arms terminated in adjustable plungers. It is used for impedance transformation.

EIA—Abbreviation for Electronic Industries Association.

Einthoven string galvanometer—A moving-coil type of galvanometer in which the coil is a single wire suspended between the poles of a powerful electromagnet.

E-I pick-off—An assembly of transformerlike laminations, the output coils of which develop a voltage proportional to the displacement of a magnetic element from the neutral position for limited rotary as well as angular travel.

ekg—Abbreviation for electrocardiograph.

elastance—Symbolized by S. In a capacitor, the ratio of potential difference between its electrodes to the charge in the capacitor. It is the reciprocal of capacitance. The unit of measure is the daraf.

$$S\ (\text{daraf}) = \frac{V}{Q}$$

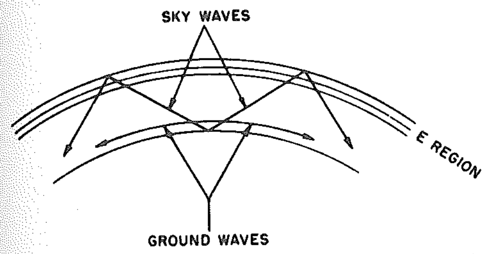
elastic collision—Collision resulting in no molecular excitation when the conservation of momentum and kinetic energy governs the energy transfer.

elastic limit—The maximum stress a solid can endure and still return to its unstrained state when the stress is removed.

elastic wave—A pure acoustic wave; a moving lattice distortion without a magnetic component.

elastivity—The resistance of an electrostatic field. It is the reciprocal of permittivity.

E-layer—One of the regular ionospheric layers with an average height of about 100 kilometers. This layer occurs during daylight hours, and its ionization is dependent on the sun's angle. The principal layer corresponds roughly to what was formerly called the Kennelly-Heaviside layer.



E-layer.

electra—A specific radionavigational aid that provides a number (usually 24) of equisignal zones. Electra is similar to sonne except that in sonne the equisignal zones as a group are periodically rotated in bearing.

electralloy—A nonmagnetic alloy frequently used in radio chassis.

electret—A permanently polarized piece of dielectric material produced by heating the material and placing it in a strong electric field during cooling. Some barium titanate ceramics can be polarized in this way, and so can carnauba waxes. The electric field of an electret corresponds somewhat to the magnetic field of a permanent magnet.

electric—Pertaining to, consisting of, containing, producing, derived from, or produced or operated by, electricity. Used interchangeably with electrical.

electrical—*See* Electric.

electrical angle—A means of specifying a particular instant in an a-c cycle. One complete cycle is considered equal to 360°; hence a half-cycle is 180° and a quarter-cycle is 90°. If one voltage reaches a peak value a quarter of a cycle after another, the electrical angle (phase difference) between the two voltages is 90°.

electrical bail—A switch action in which, upon actuation of one station, the switch changes the contact position, electrically locks the switch in that position, and releases any station previously actuated.

electrical bias—An electrically produced force tending to move the armature of a relay toward a given position.

electrical boresight—The tracking axis as determined by an electrical indication, such as the null direction of a conical scanning or monopulse antenna system or the beam maximum direction of a highly directive antenna.

electrical center—The point approximately midway between the ends of an inductor or resistor. This point divides the inductor or resistor into two equal electrical values (e.g., voltage, resistance, inductance, or number of turns).

electrical degree—A unit of time measurement applied to alternating current.

electrical discharge machining—Machining in which metal is removed by a controlled electrical spark in a dielectric.

electrical distance—The distance between two points, expressed as the length of time an electromagnetic wave in free space takes to travel between them.

electrical element—The concept in uncombined form of any of the individual building blocks from which electronic circuits are synthesized. Examples of basic electrical elements are insulation, conductance, resistance, capacitance, and inductance.

electrical erosion—The loss of contact material due to action of an electrical discharge.

electrical forming—The application of electric energy to a semiconductor device in order to permanently modify the electrical characteristics.

electrical gearing—A term used to describe the action of a system in which the output shaft rotates at a different speed from the input shaft, the ratio being established by electrical means.

electrical glass insulation—Insulating materials made from glass fibers of varying diameters, lengths, compositions, etc., including yarns, rovings, slivers, cords, and sheets or mats, bounded or treated only as necessary to their manufacture.

electrical inertia—Inductance that opposes any change in current flow through an inductor.

electrical initiation—Any source of electrical power used to start a function or sequence.

electrical interlocks—Switches mounted on contactors or other devices and operated by rods or levers. These interlocks open or close, depending on the open or closed position of the contactor or device with which they are associated, and are used to govern succeeding operations of the same or allied devices.

electrical length—Length expressed in wavelengths, radians, or degrees. Distance in wavelengths × 2π = radians; distance in wavelengths × 360 = degrees.

electrical load—A device (e.g., a speaker) comprising resistive and/or reactive components into which an amplifier, generator, etc., delivers power.

electrically operated rheostat—A rheostat used to vary the resistance of a circuit in response to some means of electrical control.

electrically operated valve—A solenoid- or motor-operated valve used in vacuum, air, gas, oil, water, or similar lines.

electrically variable inductor—An inductor in which the inductance can be controlled by a current or a voltage. It is usually made in the form of a saturable reactor with two windings. One is called the signal, or tuned winding, corresponding to the a-c or load winding of a power-handling saturable reactor; the other is the control winding and corresponds to the d-c winding of the saturable reactor.

electrical noise—Unwanted electrical energy other than cross talk in a transmission system.

electrical radian—57.296°, or $1/2\pi$ (1/6.28) of a cycle of alternating current or voltage.

electrical reset—A term applied to a relay to indicate that it is capable of being electrically reset after an operation.

electrical resistivity—The resistance of a material to passage of an electric current through it. Expressed as ohms (units of resistance) per mil foot or as microhms (millionths of an ohm) per centimeter cubed (cm^3) at a specified temperature.

electrical resolver—Special type of synchro having a single winding on the stator and two windings the axes of which are 90° apart on the rotor.

electrical sheet—Iron or steel sheets from which laminations for electric motors are punched.

electrical system—The organized arrangement of all electrical and electromechanical components and devices in a way that will properly control the particular machine tool or industrial equipment.

electrical twinning—*See* Twinning.

electrical zero—A standard synchro position at which electrical outputs have defined amplitudes and time phase.

electric arc—A discharge of energy through a gas.

electric bell—An audible signaling device consisting of one or more gongs and an electromagnetically actuated striking mechanism.

electric brazing—A brazing (alloying) process in which the heat is furnished by an electric current.

electric breakdown voltage—*See* Dielectric Breakdown Voltage.

electric breeze or wind—The emission of electrons from a sharp point of a conductor which carries a high negative potential.

electric charge—Electric energy stored on the surface of an object.

electric chronograph—A highly accurate apparatus for measuring and recording time intervals.

electric circuit—A continuous path consisting of wires and/or circuit elements over or through which an electric current can flow. If the path is broken at any point, current can no longer flow and there is no circuit.

electric contact—A separable junction between two conductors which is designed to make, carry, or break (in any sequence or singly) an electric circuit.

electric controller—A device which governs the amount of electric power delivered to an apparatus.

electric delay line—A delay line using properties of lumped or distributed capacitive and inductive elements. Can be used as a storage medium by recirculating the information-carrying signal.

electric dipole—Also called a doublet. A simple antenna comprising a pair of oppositely charged conductors capable of radiating an electromagnetic wave in response to the movement of an electric charge from one conductor to the other.

electric-discharge lamp—A sealed glass enclosure containing a metallic vapor or an inert gas through which electricity is passed to produce a bright glow.

electric displacement—*See* Electric-Flux Density.

electric-displacement density—*See* Electric-Flux Density.

electric eye—1. The layman's term for a photoelectric cell. 2. The cathode-ray, tuning-indicator tube used in some radio receivers.

electric field—The region about a charged body. Its intensity at any point is the force which would be exerted on a unit positive charge at that point.

electric-field intensity—A measure of the force exerted at a point by a unit charge at that point.

electric-field strength—The magnitude of the electric field in an electromagnetic wave. Usually stated in volts per meter. (*Also see* Dielectric Strength.)

electric-field vector—At a point in an electric field, the force on a stationary positive charge per unit charge. May be measured in either newtons per coulomb or volts per meter. This term is sometimes called the electric-field intensity, but such use of the word "intensity" is deprecated in favor of "field strength," since intensity denotes power in optics and radiation.

electric-filament lamp—A glass bulb either evacuated or filled with an inert gas and having a resistance element electrically heated to, and maintained at, the temperature necessary to produce incandescence.

electric filter—*See* Electric-Wave Filter.

electric-flux density—Also called electric-displacement density or electric displacement. At a point, the vector equal in magnitude to the maximum charge per unit area which would appear on one face of a thin metal plate introduced in the electric field at that point. The vector is normal to the plate from the negative to the positive face.

electric furnace—A furnace in which electric arcs provide the source of heat.

electric generator—A machine that transforms mechanical power into electrical power.

electric governor-controlled series-wound motor—A series-wound motor having an electric speed governor connected in series with the motor circuit. The governor is usually built into the motor.

electric hygrometer—An instrument for indicating humidity by electric means. Its operation depends on the relationship between the electric conductance and moisture content of a film of hygroscopic material.

electric hysteresis—Internal friction in a dielectric material when subjected to a varying electric field (e.g., the paper or mica dielectric of a capacitor in an a-c circuit). The resultant heat generated can eventually break down the dielectric and cause the capacitor to fail.

electrician—A person engaged in designing, making, or repairing electric instruments or machinery. Also, one who sets up an electrical installation.

electric image—The electrical counterpart of an object; i.e., the fictitious distribution of the same amount of electricity that is actually distributed on a nearby object.

electricity—The property of certain particles to possess a force field which is neither gravitational nor nuclear. The type of force field associated with electrons is defined as negative and that associated with protons and positrons as positive. The fundamental unit is the charge of an electron: 1.60203×10^{-19} coulomb. Electricity can be further classified as static electricity or dynamic electricity. Static electricity in its strictest sense refers to charges at rest, as opposed to dynamic electricity, or charges in motion. Static electricity is sometimes used as a synonym for triboelectricity or frictional electricity.

electric light—Light produced by an electric lamp.

electric lines of force—In an electric field, curves the tangents of which at any point give the direction of the fields at that point.

electric meter—A device that measures and registers the amount of electricity consumed over a certain period of time.

electric mirror—*See* Dynode.

electric moment—For two charges of equal magnitude but opposite polarities, a vector equal in magnitude to the product of the magnitude of either charge by the distance between the centers of the two charges. The direction of the vector is from the negative to the positive charge.

electric motor—A device which converts electrical energy into rotating mechanical energy.

electric network—A combination of any number of electric elements, having either lumped or distributed impedances, or both.

electric oscillations—The back-and-forth flow of electric charges whenever a circuit containing inductance and capacitance is electrically disturbed.

electric potential—A measure of the work required to bring a unit positive charge from an infinite distance or from one point to another (the difference of potential between two points).

electric precipitation—The collecting of dust or other fine particles floating in the air. This is done by inducing a charge in the particles, which are then attracted to highly oppositely charged collector plates.

electric probe—A rod inserted into an electric field during a test to detect d-c, audio, or r-f energy.

electric reset—A qualifying term indicating that the contacts of a relay must be reset electrically to their original positions following an operation.

electric shield—A housing, usually aluminum or copper, placed around a circuit to provide a low-resistance path to ground for high frequency radiations and thereby prevent interaction between circuits.

electric strain gage—A device which detects the change in shape of a structural member under load and causes a corresponding change in the flow of current through the device.

electric strength—The maximum electric charge a dielectric material can withstand without rupturing. (*Also see* Dielectric Strength.)

electric stroboscope—An instrument for observing or for measuring the speed of rotating or vibrating objects by electrically producing periodic changes in the intensity of light used to illuminate the object.

electric tachometer—A tachometer (rpm indicator) that utilizes voltage or electrical impulses.

electric telemeter—A system consisting of a meter which measures a quantity, a transmitter which sends the information to a distant station, and a receiver which indicates or records the quantity measured.

electric transcription—In broadcasting, a disc recording of a message or a complete program.

electric transducer—A device actuated by electric waves from one system and supplying power, also in the form of electric waves, to a second system.

electric tuning—A system by which a radio receiver is tuned to a station by pushing a button (instead of, say, turning a knob).

electric vector—A component of the electromagnetic field associated with electromagnetic radiation. The component is of the nature of an electric field. The electric vector is supposed to coexist with, but act at right angles to, the magnetic vector.

electric wave—Another term for the electromagnetic wave produced by the back-and-forth movement of electric charges in a conductor.

electric-wave filter—Also called electric filter. A device that separates electric waves of different frequencies.

electrification—1. The process of establishing an excess of positive or negative charges in a material. 2. The process of applying a voltage to a component or device.

electroacoustic—Pertaining to a device (e.g., a speaker and a microphone) which involves both electric current and sound-frequency pressures.

electroacoustic transducer—A device that receives excitations from an electric system and delivers an output to an acoustic system, or vice versa. A speaker is an example of the first, and a microphone is an example of the second.

electroanalysis—The process of determining the quantity of an element or compound in an electrolyte solution by depositing the element or compound on an electrode by electrolysis.

electrobiology—The science concerned with electrical phenomena of living creatures.

electrobioscopy—The application of a voltage to produce muscular contractions.

electrocardiogram — Essentially an electromyogram of the heart muscle. All muscular activity in the body is characterized by the discharge of polarized cells, the aggregate current from which causes a voltage drop that can be measured on the skin. A changing emf will appear between electrodes connected to the arms, legs, and chest, which rises and falls with heart action such that the period of the resulting waveform is the time between heartbeats. Various positive and negative peaks within one cycle of this waveform have been lettered P, Q, R, S, and T, a notation which aids in subsequent analysis and diagnosis.

electrocardiograph—A medical instrument for detecting irregularities in the action of a human heart. It measures the changes in voltage occurring in the human body with each heartbeat. Abbreviated ekg.

electrochemical deterioration—A process in which autocatalytic electrochemical reactions produce an increase in conductivity and in turn ultimate thermal failure.

electrochemical equivalent—The weight of an element, compound, radical, or ion involved in a specified electrochemical reaction during passage of a specified quantity of electricity such as a coulomb.

electrochemical junction transistor — A junction transistor produced by etching an N-type germanium wafer on opposite sides with jets of a salt solution such as indium chloride.

electrochemical recording — A recording made by passing a signal-controlled current through a sensitized sheet of paper. The paper reacts to the current and thereby produces a visual record.

electrochemical transducer—A device which uses a chemical change to measure the input parameter, and the output of which is a varying electrical signal proportional to the measurand.

electrochemistry—That branch of science concerned with reciprocal transformations of chemical and electrical energy. This includes electrolysis, electroplating, the charge and discharge of batteries, etc.

electrocoagulation—The process of solidifying tissue by means of a high frequency electrical current.

electrocution—Killing by means of an electric current.

electrode—1. In an electronic tube, the conducting element that does one or more of the following: emits or collects electrons or ions, or controls their movement by means of an electric field on it. 2. In semiconductors, the element that does one or more of the following: emits or collects electrons or holes, or controls their movements by means of an electric field on it. 3. In electroplating, the metal being plated. 4. A conductor by means of which a current passes into or out of a fluid or an organic material such as human skin; often one terminal of a lead. 5. A metallic conductor such as in an electrolytic cell, where conduction by electrons is changed to conduction by ions or other charged particles.

electrode admittance—The alternating component of the electrode current divided by that of the electrode voltage (all other electrode voltages maintained constant).

electrode capacitance—The capacitance between one electrode and all the other electrodes connected together.

electrode characteristic—The relationship, usually shown by a graph, between the electrode voltage and current, all other electrode voltages being maintained constant.

electrode conductance—The quotient of the in-phase component of the electrode alternating current divided by the electrode alternating voltage, all other electrode voltages being maintained constant. This is a variational and not a total conductance.

electrode current—Current passing into or out of an electrode.

electrode dark current—In phototubes, the component of electrode current that flows in the absence of ionizing radiation and optical photons. Also called dark current.

electrode dissipation—The power which an electrode dissipates as heat when bombarded by electrons and/or ions and radiation from nearby electrodes.

electrode drop—The voltage drop produced in an electrode by its resistance.

electrode impedance—The reciprocal of electrode admittance.

electrodeless discharge — A luminous discharge produced by means of a high-frequency electric field in a gas-filled glass tube that has no internal electrodes.

electrodeposition—Also called electrolytic deposition. The process of depositing a substance on an electrode by electrolysis, as in electroplating, electroforming, electrorefining, or electrotinning.

electrode potential—The instantaneous voltage on an electrode. Its value is usually given with respect to the cathode of a vacuum tube.

electrode reactance—The imaginary component of electrode impedance.

electrode resistance—The reciprocal of electrode conductance. It is the effective parallel resistance, not the real component of electrode impedance.

electrode voltage—The voltage between an electrode and the cathode or a specified point of a filamentary cathode. The terms "grid voltage," "anode voltage," "plate voltage," etc., designate the voltage between these electrodes and the cathode. Unless otherwise stated, electrode voltages are measured at the available terminals.

electrodialytic process — A process for producing fresh water by using a combination of electric current and two types of chemically treated membranes.

electrodynamic—Pertaining to electric current, electricity in motion, and the actions and effects of magnetism and induction.

electrodynamic braking—A method of stopping a tape-deck motor gently by the application of a predetermined voltage to the motors.

electrodynamic instrument—An instrument which depends for its operation on the reaction between the current in one or more moving coils and the current in one or more fixed coils.

electrodynamics—The science dealing with the various phenomena of electricity in motion, including interactions of currents with each other, with their associated magnetic fields, and with other magnetic fields.

electrodynamic speaker—A speaker consisting of an electromagnet called the field coil, through which a direct current flows.

electrodynamometer—An instrument for detecting or measuring an electric current by determining the mechanical reactions between two parts of the same circuit.

electroencephalogram — A waveform obtained by plotting brain voltages (available between two points on the scalp) against time. An electroencephalogram is not necessarily a periodic function, although it can be—particularly if the patient is unconscious. These voltages are of extremely low level and require recording apparatus which display excellent noise rejection.

electroencephalograph (eeg) — An instrument for measuring and recording the rhythmically varying potentials produced by the brain by the use of electrodes applied to the scalp.

electroencephaloscope — An instrument for detecting brain potentials at many different sections of the brain and displaying them on a cathode-ray tube.

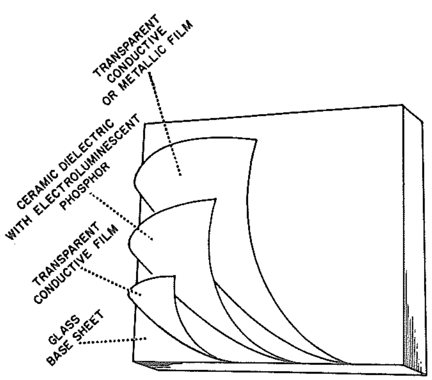
electroforming—1. Also called electrodeposition and electroplating. Making a metal object by using electrolysis to deposit a metal on an electrode. 2. Creating a PN junction by passing a current through point contacts on a semiconductor.

electrographic recording—Also called electrostatography. The producing of a visible record by using a gaseous discharge between two or more electrodes to form electrostatically charged patterns on an insulator. (*Also see* Electrostatic Electography.)

electrokinetics—The branch of physics concerned with electricity in motion.

electroluminescence — Luminescence resulting from a high-frequency discharge through a gas or from application of an alternating current to a layer of phosphor.

electroluminescent lamp—A lamp in the shape of a panel which is decorative as well as illuminative. It consists primarily of a capacitor having a ceramic dielectric with electroluminescent phosphor. The amount of illumination is determined by the voltage across the layer and by the frequency applied to it.



TRANSPARENT CONDUCTIVE OR METALLIC FILM
CERAMIC DIELECTRIC WITH ELECTROLUMINESCENT PHOSPHOR
TRANSPARENT CONDUCTIVE FILM
GLASS BASE SHEET

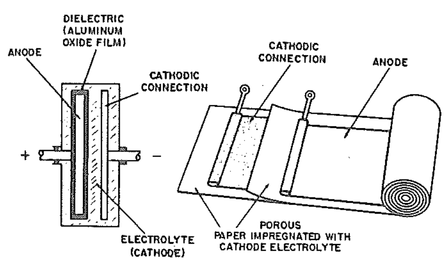
Electroluminescent lamp.

electrolysis—1. The process of changing the chemical composition of a material (called the electrolyte) by sending an electric current through it. 2. The decay of an underground structure by chemical action due to stray electrical currents.

electrolyte—1. A substance in which the conduction of electricity is accompanied by chemical action. 2. The paste which forms the conducting medium between the electrodes of a dry cell, storage cell, or electrolytic capacitor. 3. A substance which, when dissolved in a suitable liquid (often water), dissociates into ions, thus rendering the liquid electrically conducting.

electrolytic—Pertaining to or made by electrolysis; deposited by electrolysis; pertaining to or containing an electrolyte.

electrolytic capacitor—A capacitor consisting of two conducting electrodes, with the anode having a metal oxide film formed on it. The film acts as the dielectric or insulating medium. It is repairable in the presence of an operating electrolyte, usually an acid or salt. Generally used for filtering, bypassing, coupling, or decoupling.



DIELECTRIC (ALUMINUM OXIDE FILM)
ANODE
CATHODIC CONNECTION
CATHODIC CONNECTION
ANODE
+
-
ELECTROLYTE (CATHODE)
POROUS PAPER IMPREGNATED WITH CATHODE ELECTROLYTE

Electrolytic capacitor.

electrolytic cell—In a battery, the container, two electrodes, and the electrolyte.

electrolytic conduction—The flow of current between electrodes immersed in an electrolyte. It is caused by the movement of ions from one electrode to the other when a voltage is applied between them.

electrolytic conductivity — Also called specific conductance. A measure of the ability of a solution to carry an electric current. Defined as the reciprocal of the resistance in ohms of a 1-cm cube of the liquid at a specified temperature. The units of specific conductance are the reciprocal ohm-cm (or mho/cm) and one millionth of this, micromho/cm. (High-quality condensed steam and distilled or demineralized water have specific conductances at room temperatures as low as or lower than 1 micromho/cm).

electrolytic corrosion—*See* Corrosion.

electrolytic deposition — *See* Electrodeposition.

electrolytic dissociation—The breaking up of molecules into ions in a solution.

electrolytic interrupter—A device which is tilted to change the current through it.

electrolytic iron—Iron obtained by an electrolytic process. The iron possesses good magnetic qualities and is exceptionally free of impurities.

electrolytic potential—The difference in potential between an electrode and the immediately adjacent electrolyte, expressed in terms of some standard electrode difference.

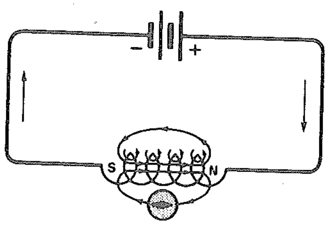
electrolytic recording—A form of facsimile recording in which ionization causes a chemically moistened paper to undergo a change.

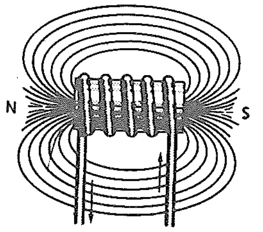
electrolytic rectifier — A rectifier consisting of metal electrodes in an electrolyte, in which rectification of alternating current is accompanied by electrolytic action. A polarization film formed on one of the electrodes permits current in one direction but not in the other.

electrolytic refining—The refining or purifying of metals by electrolysis.

electrolytic switch — A switch having two electrodes projecting into a chamber containing a precisely measured quantity of a conductive electrolyte, leaving an air bubble of predetermined width. When the switch is tilted from true horizontal, the bubble shifts position and changes the amount of electrolyte in contact with the electrodes, thereby changing the amount of current passed by the switch. Used as a leveling switch in gyro systems.

electrolyzer—An electrolytic cell that produces alkalies, metals, chlorine, or other allied products.





Electromagnet.

electromagnet—A temporary magnet consisting of a solenoid with an iron core. A magnetic field exists only while current flows through the solenoid.

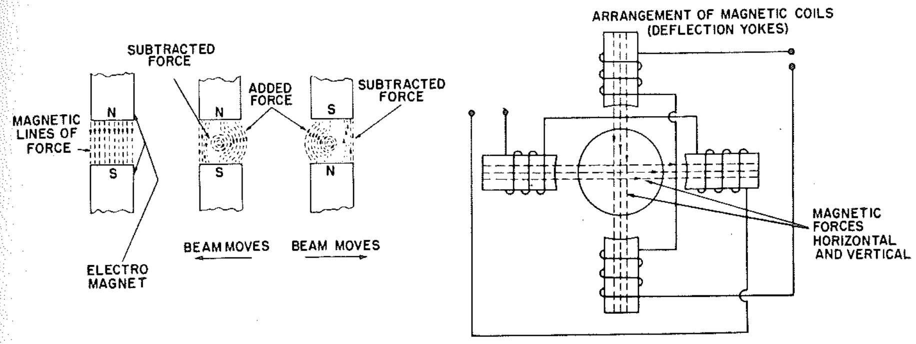
electromagnetic—Having both magnetic and electric properties.

electromagnetic cathode-ray tube—A cathode-ray tube which uses electromagnetic deflection to deflect the electron beam.

electromagnetic communications — The electromagnetic wave conductor is space itself. The electromagnetic frequencies available today for communications fall into two categories: frequencies which form "wireless" communications (such as visual light of fairly high frequency), and frequencies man uses for wireless communications (such as radio, short wave, and microwave transmitting, of relatively lower frequencies). In communicating by radio, short wave, and microwave frequencies, translators similar in principle to those used in electrical communications are needed, although the equipment requirement increases.

electromagnetic coupling—The mutual relationship between two separate but adjacent wires when the magnetic field of one induces a voltage in the other.

electromagnetic crack detector—An instrument for detecting hidden cracks in iron or steel objects by magnetic means.



Electromagnetic deflection coil.

electromagnetic deflection—The deflection of an electron stream by means of a magnetic field. In a television receiver, the magnetic field for deflecting the electron beam horizontally and vertically is produced by two pairs of coils, called the deflection yoke, around the neck of the picture tube.

electromagnetic deflection coil — A coil, around the neck of a cathode ray tube, for deflecting the electron beam.

electromagnetic delay line—A delay line the operation of which is based on the time of propagation of electromagnetic waves through distributed or lumped capacitance and inductance.

electromagnetic energy — Forms of radiant energy such as radio waves, heat waves, light waves, X-rays, gamma rays, and cosmic rays.

electromagnetic environment—The r-f field or fields existing in an area or desired in an area to be shielded.

electromagnetic field—1. The field of influence produced around a conductor by the current flowing through it. 2. A rapidly moving electric field and its associated magnetic field. The latter is perpendicular to both the electric lines of force and their direction.

electromagnetic focusing—In a television picture tube, the focusing produced by a coil mounted on the neck. Direct current through the coil produces magnetic field lines parallel to the tube axis.

electromagnetic horn—A horn-shaped structure that provides highly directional radiation of radio waves in the 100-megahertz or higher frequency range.

electromagnetic induction — The voltage produced in a coil as the number of magnetic lines of force (flux linkages) passing through the coil changes.

electromagnetic interference—Electromagnetic phenomena which, either directly or indirectly, can contribute to a degradation in performance of an electronic receiver or system. (The phrases "radio interference," "radio-frequency interference," and "noise" have been employed at various times in the same context.)

electromagnetic lens—An electron lens in which the electron beams are focused electromagnetically.

electromagnetic mirror—A surface or region capable of reflecting radio waves, such as one of the ionized layers in the upper atmosphere.

electromagnetic oscillograph — An oscillograph in which a mechanical motion is derived from electromagnetic forces to produce a record.

electromagnetic radiation — That form of energy which is characterized by transversely oscillating electric and magnetic fields and which propagates at velocity "c" in free space. At a sufficient distance from the source, the electric-field vector and the magnetic-field vector are at right angles to each other, forming a right-handed (coordinate) system. In an ionized medium, a longitudinal component may be present.

electromagnetic relay—An electromagnetically operated switch composed of one or more coils and armatures. Whenever current flows through the coil, its magnetic field attracts the armature and completes a circuit.

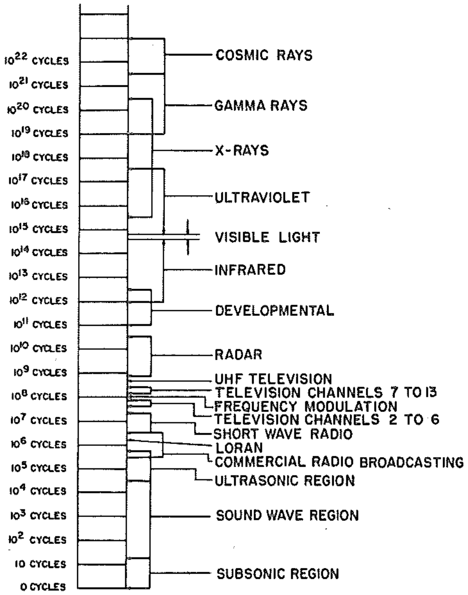
electromagnetic repulsion — The repelling action between like poles of electromagnets.

electromagnetics — In physics, the branch concerned with the relationships between electric currents and their associated magnetic fields.

electromagnetic spectrum—A chart or graph showing the relationship between all known electromagnetic waveforms classified by wavelengths.

electromagnetic theory of light—The theory which states that electromagnetic and light waves have identical properties.

electromagnetic transduction — 1. Conversion of the measurand into the output induced in a conductor by a change in magnetic flux. 2. A wave produced by the oscillation of an electric charge. 3. A wave in which there are both electric and magnetic displacements. 4. A transverse wave associated with the transmission of electromagnetic energy.



Electromagnetic radiation spectrum chart.

electromagnetic-type microphones—Microphones in which the voltages are varied by an electromagnet (namely, ribbon or velocity, dynamic or moving-coil, and reluctance or moving-vane microphones).

electromagnetic unit—Abbreviated emu. A unit .of electricity based primarily on the magnetic effect of an electric current. The fundamental centimeter-gram-second unit is the abampere. Now considered obsolete.

electromagnetic vibrator—A mechanical device for interrupting the flow of direct current and thereby making it a pulsating current. This is done where a circuit requires an alternating current to operate. A reed within the vibrator is alternately attracted to two electromagnets.

electromagnetic wave—The radiant energy produced by oscillation of an electric charge. It includes radio, infrared, visible and ultraviolet light waves, and X-, gamma, and cosmic rays.

electromagnetism — The magnetic field around a wire or other conductor when, and only when, current passes through it.

electromechanical—Any device using electrical energy to produce mechanical movement.

electromechanical bell—A bell with a prewound spring-driven clapper which is tripped electrically to ring the bell.

electromechanical breakdown—A mechanical runaway that occurs when the mechanical restoring force fails to balance the electrical compressive force.

electromechanical chopper — *See* Contact Modulator.

electromechanical frequency meter — A meter which uses the resonant properties of mechanical devices to indicate frequency.

electromechanical recorder—A device which transforms electrical signals into equivalent mechanical motion which is transferred to a medium by cutting, embossing, or writing.

electromechanical timer—Usually refers to a motor-driven timer, with or without an electrically operated clutch. Can also apply to pneumatic and thermal timers, or slow pull-in or drop-out relays.

electromechanical transducer — A device that transforms electrical energy into mechanical energy or vice versa. A speaker is an example of the first, and a microphone of the second.

electromechanics—That branch of electrical engineering concerned with machines producing or operated by electric currents.

electrometallurgy—That branch of science concerned with the application of electrochemistry to the extraction or treatment of metals.

electrometer—1. An electrostatic instrument that measures a potential difference or an electric charge by the mechanical force exerted between electrically charged surfaces. 2. A d-c vacuum-tube voltmeter with an extremely high input resistance, usually around 10^{10} megohms, as opposed to 10 megohms or less for a conventional type.

electrometer amplifier—An amplifier circuit having sufficiently low-current drift and other noise components, sufficiently low amplifier input-current offsets, and adequate power and current sensitivities to be usable for measuring current variations of considerably less than 10^{-12}A.

electrometer tube—A vacuum tube having a very low control-electrode conductance, to facilitate the measurement of extremely small direct currents and voltages.

electromotive force—Abbreviated emf. The force which causes electricity to flow when there is a difference of potential between two points. The unit of measurement is the volt.

electromotive series—A list of metals arranged in decreasing order of their tendency to pass into ionic form by losing electrons.

electromyogram—Classically, a waveform of the contraction of a muscle as a result of electrical stimulation. Usually the stimulation comes from the nervous system (normal muscular activity). The record of potential difference between two points on the surface of the skin resulting from the activity or action potential of a muscle.

electromyograph — An instrument for measuring and recording potentials generated by muscles.

electromyography—An electronic method of measuring and recording the electrical activity of muscles.

electron—Also called negatron. One of the natural elementary constituents of matter; it carries a negative electric charge of one electronic unit and has approximately 1/1840th the mass of a hydrogen atom or 9.107×10^{-28} gram. Electrons surround the positively charged nucleus and determine the chemical properties of the atom. Positive electrons, or positrons, also exist.

electron attachment—Process by which an electron is attached to a neutral molecule to form a negative ion. Often characterized by the attachment coefficient η, which is the number of attachments per centimeter of drift. Also characterized by the ratio $h = \sigma_a/\theta$, where σ_a is the attachment cross section and θ the total cross section.

electron avalanche — The chain reaction started when one free electron collides with one or more orbiting electrons and frees them. The free electrons then free others in the same manner, and so on.

electron beam—A narrow stream of electrons moving in the same direction under the influence of an electric or magnetic field.

electron-beam generator—A velocity-modulated generator, such as a klystron tube, used to generate extremely high frequencies.

electron-beam instrument — Also called a cathode-ray instrument. An instrument in which a beam of electrons is deflected by an electric or magnetic field (or both). Usually the beam is made to strike a fluorescent screen so the deflection can be observed.

electron-beam machining — A process in which controlled electron beams are used to weld or shape a piece of material.

electron-beam magnetometer — An instrument that measures the intensity and direction of magnetic forces by the immersion of an electron beam into the magnetic field.

electron-beam mode discharge—A form of discharge produced by a perforated-wall hollow cathode operating under conditions of pressure, voltage, and geometry usually associated with the abnormal glow discharge.

electron-beam tube—An electron tube which depends for its operation on the formation and control of one or more electron beams.

electron-beam welding—The process of using a focused beam of electrons to heat materials to the fusion point.

electron charge — Also called elementary charge. The charge of a single electron. Its value is 1.60203×10^{-19} coulomb. The fundamental unit of electrical charge.

electron-coupled oscillator — Abbreviated ECO. A circuit using a multigrid tube in which the cathode and two grids operate as a conventional oscillator and the electron stream couples the plate-circuit load to the oscillator.

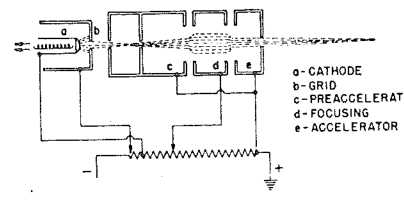
electron coupling—In vacuum (principally multigrid) tubes, the transfer of energy between electrodes as electrons leave one and go to the other.

electron drift—The movement of electrons in a definite direction through a conductor, as opposed to the haphazard transfer of energy from one electron to another by collision.

electronegative—Having an electric polarity that is negative.

electron emission—The freeing of electrons into space from the surface of a body under the influence of heat, light, impact, chemical disintegration, or a potential difference.

electron flow—The movement of electrons from a negative to a positive point in a metal or other conductor, or from a negative to a positive electrode through a liquid, gas, or vacuum.



Electron gun.

electron gun — 1. An electrode structure which produces and may control focus and may deflect and converge one or more electron beams. 2. The portion of a cathode-ray tube or camera tube which emits a beam of controlled electrons.

electronic—1. Pertaining to that branch of science which deals with the motion, emission, and behavior of currents of free electrons, especially in vacuum, gas, or phototubes and special conductors or semiconductors. This is contrasted with electric, which pertains to the flow of large currents in metal conductors. 2. Of or pertaining to devices, circuits, or systems using the principle of electron flow through a conductor—for example, *electronic* control, equipment, instrument, circuit.

electronic autopilot — An arrangement of gyroscopes, electronic amplifiers, and servomotors for detecting deviations in the flight of an aircraft and applying the required corrections directly to its control cables.

electronic "bug"—A keying system which converts the Morse signals from a hand key into correctly proportioned and spaced dots and dashes.

electronic camouflage — Use of electronic means, or exploitation of electronic characteristics, to reduce, submerge, or eliminate the radar-echoing properties of a target.

electronic circuit—A circuit containing one or more electron tubes, transistors, magnetic amplifiers, etc.

electronic commutator — A type of switch which provides a continuous switching or sampling of a number of circuits by means of a radial-beam electronic tube or electronic switching circuit.

electronic control — Also called electronic regulation. The control of a machine or condition by electronic devices.

electronic counter—An instrument capable of counting up to several million electrical pulses per second.

electronic countermeasures—Reducing the effectiveness of enemy equipment employing or affected by electromagnetic radiations. This is done by using appropriate electronic devices.

electronic countermeasures control—1. Collection and sorting of large quantities of data for the purpose of measuring and defining radar signals. 2. Examination of the data received in order to determine selection and switching of countermeasure devices with little or no time delay.

electronic coupling—The method of coupling electrical energy from one circuit to another through the electron stream in a vacuum tube.

electronic data-processing center—A place in which is kept automatically operated equipment, including computers, designed to simplify the interpretation and use of data gathered by instrumentation installations or information-collection agencies. Abbreviated EDP center.

electronic data-processing machine—Abbreviated EDPM. A machine or its device and attachments used primarily in or with an electronic data-processing system.

electronic data-processing system — Any machine or group of automatically intercommunicating machines capable of entering, receiving, sorting, classifying, computing and/or recording alphabetical or numerical accounting or statistical data (or all three) without intermediate use of tabulating cards.

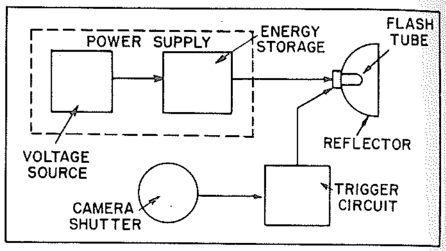
electronic deception—Radiation or reradiation of electromagnetic waves to mislead the enemy in the interpretation of data received by his electronic equipment.

electronic differential analyzer—A form of analog computer using interconnected electronic integrators to solve differential equations.

electronic digital computer — A machine which uses electronic circuitry in the main computing element to perform arithmetic and logical operations on digital data (i.e., data represented by numbers or alphabetic symbols) automatically, by means of an internally stored program of machine instruction. Such devices are distinguished from calculators, on which the sequence of instructions is externally stored and is impressed manually (desk calculators) or from tape or cards (card-programmed calculators).

electronic efficiency — The ratio of (a) the power at the desired frequency delivered by the electron stream to the oscillator or amplifier circuit to (b) the direct power supplied to the stream.

electronic flash—Also called strobe. The firing of special light-producing, high-voltage, gas-filled glass tubes with a high instantaneous surge of current furnished by a capacitor or bank of capacitors which have been charged from a high-voltage source (usually 450 volts or higher).



Electronic flash unit.

electronic flash tube—*See* Flash Tube.

electronic frequency synthesizer—A device which generates two or more selectable frequencies from one or more fixed-frequency sources.

electronic heating — Also called high-frequency heating. A method of heating a material by inducing a high-frequency current in it or having the material act as the dielectric between two plates charged with a high-frequency current.

electronic industries — Industrial organizations engaged in the manufacture, design, development, and/or substantial assembly of electronic equipment, systems, assemblies, or the components thereof.

Electronic Industries Association (EIA)—A trade association of the electronics industry. Some of its functions are the formulation of technical standards, dissemination of marketing data, and the maintenance of contact with government agencies in matters relating to the electronics industry.

electronic instrument — Any instrument which depends for its operation on the action of either one or more electron devices.

electronic intelligence — The technical and intelligence information derived from foreign noncommunications electromagnetic radiations emanating from other than nuclear detonations or radioactive sources.

electronic keying — A method of keying whereby the dots and dashes are produced solely by electronic means.

electronic line scanning—Facsimile scanning in which a spot on a cathode-ray tube moves across the copy electronically while the record sheet or subject copy is moved mechanically in a perpendicular direction.

electronic microphone—A device which depends for its operation on the generation of a voltage by the motion of one of the electrodes in a special electron tube.

electronic mine detector—*See* Mine Detector.

electronic multimeter—A device employing the characteristics of an electron-tube circuit for the measurement of electrical quantities, at least one of which is voltage or current, on a single calibrated scale.

electronic music—The electronic generation and processing of audio signals or the electronic processing of natural sound, and the manipulation and arrangement of these signals via tape recorders into a finished musical composition.

electronic organ—The electronic counterpart of the pipe organ. All tones and tone variations such as vibrato, tremolo, etc., are produced by electronic circuits instead of by pipes.

electronic packaging — The coating or surrounding of an electronic assembly with a dielectric compound.

electronic photometer—An electronic instrument for measuring intensity of light, brightness of paints, turbidity of solutions, etc. It comprises a phototube, an electronic direct-current amplifier, and an indicating instrument.

electronic power supply — A circuit which transforms electrical input energy, alternating or direct current—into output energy—alternating or direct current. (Sources operating on rotating machine principles, or deriving electrical power from other energy forms such as batteries and solar cells, are excluded.) Supplies covered by this definition fall into one of four groups: 1. A-c in, d-c out—most common supplies. 2. A-c in, a-c out—line regulators, variable frequency supplies. 3. D-c in, d-c out—converters. 4. D-c in, a-c out—inverters.

electronic products—Materials, parts, components, subassemblies, and equipment which employ the principles of electronics in performing their major functions. These products may be used as instruments and controls in communications, detection, amplification, computation, inspection, testing, measurement, operation, recording, analysis, and other functions employing electronic principles.

electronic profilometer—An electronic instrument for measuring surface roughness. The diamond-point stylus of a permanent-magnet dynamic pickup is moved over the surface being examined. The resultant variations in voltage are amplified, rectified, and measured with a meter calibrated to read directly in micro-inches of deviation from smoothness.

electronic reconnaissance—Search for electromagnetic radiations to determine their existence, source, and pertinent characteristics for electronic warfare purposes.

electronic rectifier—A rectifier using electron tubes or equivalent semiconductor elements as rectifying elements.

electronic regulation — *See* Electronic Control.

electronic relay—An electronic circuit that provides the functional equivalent of a relay, but has no moving parts.

electronics—1. The field of science and engineering concerned with the behavior of electrons in devices and the utilization of such devices. 2. Of or pertaining to the field of electronics, such as electronics engineer, course, laboratory, committee.

electronic stethoscope — An electronic amplifier of sounds within a body. Its selective controls permit tuning for low heart tones or high pulmonary tones. It has an auxiliary output for recording or viewing audio patterns.

electronic stimulator—A device for applying electronic pulses or signals to activate muscles, or to identify nerves, or for muscular therapy, etc.

electronic switch—1. A circuit element causing a start and stop action or a switching action electronically, usually at high speeds. 2. A test instrument for presenting two waveshapes on a single-gun cathode-ray tube.

electronic thermal conductivity—The part of the thermal conductivity due to the transfer of thermal energy by means of electrons and holes.

electronic timer—1. A synchronizer, pulse generator, modulator, or keyer that originates a series of continuous control pulses at an unvarying repetition rate known as the pulse-recurrence frequency. 2. A timer using electronic circuits (either tube or transistor type) to control a time period, in place of a motor or other means.

electronic tube relay—A relay that employs electronic tubes as components.

electronic tuning—1. Altering the frequency of a reflex klystron oscillator by changing the repeller voltage. 2. Frequency changing in a transmitter or receiver by changing a control voltage rather than circuit components.

electronic voltmeter—Also called vacuum-tube voltmeter. A voltmeter which utilizes the rectifying and amplifying properties of electron tubes and their circuits to secure such characteristics as high input impedance, wide frequency range, peak-to-peak indications, etc.

electronic volt-ohmmeter—A device employing the characteristics of an electron-tube circuit for the measurement of voltage and resistance on a single calibrated scale.

electronic warfare—Military usage of electronics to reduce an enemy's effective use of radiated electromagnetic energy and to insure our own effective use.

electronic waveform synthesizer—An instrument using electron devices to generate an electrical signal of a desired waveform.

electron image tube — A cathode-ray tube having a photoemissive mosaic upon which an optical image is projected, and an electron gun to scan the mosaic and convert the optical image into corresponding electrical current.

electron lens—The convergence of the electrons into a narrow beam in a cathode-ray tube by deflecting them electromagnetically or electrostatically. So called because its action is analogous to that of an optical lens.

electron microscope—An instrument which uses an electron beam to penetrate thin samples of a material. It is possible to magnify images of the material on a screen or film up to 350,000 times.

electron multiplier — A vacuum tube in which electrons liberated from a photosensitive cathode are attracted successively to a series of electrodes called dynodes. In doing so, each electron liberates others by secondary emission and thereby greatly increases the number of electrons flowing in the tube.

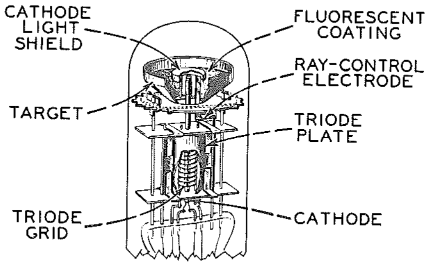
electron-multiplier section—A section of an electron tube in which an electron current is amplified by one or more successive dynode stages.

electron optics—The branch of electronics concerned with the behavior of the electron beam under the influence of electrostatic and electromagnetic forces.

electron-pair bond—A valence bond formed by two electrons, one from each of two adjacent atoms.

electron paramagnetic resonance—A condition in which a paramagnetic solid subjected to two magnetic fields, one of which is fixed and the other normal to the first and varying at the resonance frequency, emits electromagnetic radiation associated with changes in the magnetic quantum number of the electrons.

electron-ray tube—Also called a "magic eye." A tube which indicates visibly on a fluorescent target the effects of changes in control-grid voltage applied to the tube. Used as a tuning indicator in receivers.



Electron-ray tube.

electron scanning—The moving of an electron beam back and forth and/or up and down by deflecting the beam electromagnetically or electrostatically.

electron spin—The twirling motion of an electron, independent of any orbital motion.

electron telescope—An apparatus for seeing through haze and fog. An infrared image is formed optically on the photoemissive mosaic of an electron-image tube and then made visible by the tube.

electron transit time—The time required for electrons to travel between two electrodes in a vacuum tube. This time is extremely important in tubes designed for ultrahigh frequencies.

electron tube—An electron device in which the electrons move through a vacuum or gaseous medium within a gas-tight envelope.

electron unit—The unit of charge (negative or positive) equal to the charge on an electron.

electron volt — Abbreviated ev or eV. The amount of kinetic energy gained by an electron when it is accelerated through an electric potential difference of 1 volt. It is equivalent to 1.603×10^{-12} erg. It is a unit of energy or work, not of voltage.

electron-wave tube — An electron tube in which streams of electrons having different velocities interact and cause a progressive change in signal modulation along their length.

electro-optical transistor—A transistor capable of responding in nanoseconds to both light and electrical signals.

electropad — The part of an electrocardiograph body electrode that makes contact with the skin.

electrophonic effect—The sensation of hearing produced when an alternating current of suitable frequency and magnitude from an external source is passed through an animal or human body.

electrophoresis—The movement of particles or ions in solution caused by applying an electric field, as reported by O. Lodge in 1886.

electrophoresis apparatus — An apparatus for causing migration of charged particles (ions) in solution in an electric field. Types include paper, cascading electrodes, high voltage, gel, and thin layer.

electrophoresis scanner—An instrument for reading bands on paper strips or gel, for the purpose of measuring particle movement due to electrophoresis.

electrophorus—An early type of static-electricity generator.

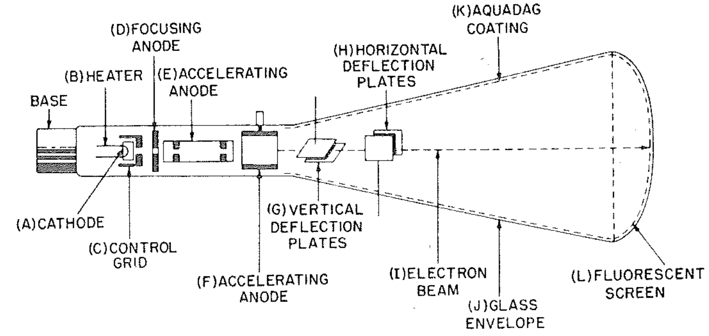
electrophotographic process — The process in which images are formed by various electrical and photographic means. Examples are processes employing selenium-coated drums or zinc-oxide–coated paper.

electrophotometer—An instrument using a photoelectric sensor for colorimetric determinations.

electroplaques — Individual electricity-producing cells in eels and other electric fishes connected in series-parallel arrays, like miniature elements of a battery. They are usually thin waferlike cells, the two surfaces of which differ markedly.

electroplate—To deposit a metal on the surface of certain materials by electrolysis.

electroplating—The electrodeposition of an adherent metal coating on a conductive object for protection, decoration, or other purposes. The object to be plated is placed in an electrolyte and connected to one terminal of a d-c voltage source. The metal to be deposited is similarly immersed and connected to the other terminal. Ions of the metal provide transfer to the metal as they make up the current between the electrodes.



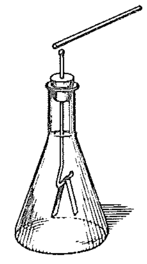
Electrostatic deflection.

electropolishing—The process of producing a smooth, lustrous surface on a metal by making it the anode in an electrolytic solution and preferentially dissolving the minute protuberances.

electrorefining—*See* Electroplating.

electroretinograph—An instrument for measuring the electrical response of the human retina to light stimulation.

electroscope—An electrostatic instrument for measuring a potential difference or an electric charge by means of the mechanical force exerted between electrically charged surfaces.



Electroscope.

electrosensitive recording—The passage of electric current into a sheet of sensitive paper to produce a permanent record.

electroshock—A state of shock produced by passing an electric current through the brain. It is useful in the treatment of certain mental disorders.

electrospinograph — A device for detecting and recording electric signals of the spinal cord.

electrostatic—Pertaining to static electricity —i.e., electricity, or an electric charge, at rest.

electrostatic actuator—An apparatus comprising an auxiliary external electrode which permits known electrostatic forces to be applied to the diaphragm of a microphone for the purpose of obtaining a primary calibration.

electrostatic capacitor — Two conducting electrodes separated by an insulating material such as air, ceramic, mica, gas, paper, plastic film, or glass. These are generally high-impedance devices.

electrostatic charge — An electric charge stored in a capacitor or on the surface of an insulated object.

electrostatic component — The portion of radiation due to electrostatic fields.

electrostatic-convergence principle — The principle of electron-beam convergence through use of an electrostatic field.

electrostatic coupling—Method of coupling by which charges on one surface influence those on another through capacitive action.

electrostatic deflection—The method of deflecting an electron beam by passing it between charged plates mounted inside a cathode-ray tube.

electrostatic electrography—The branch of electrostatography which produces a visible record by employing an insulating medium to form latent electrostatic patterns without the aid of electromagnetic radiation.

electrostatic electrophotography — That branch of electrostatography which produces a visible record by employing a photoresponsive medium to form latent electrostatic images with the aid of electromagnetic radiation.

electrostatic energy—The energy contained in electricity at rest, such as in the charge of a capacitor.

electrostatic field—The vector force field set up in the vicinity of nonmoving electrical charges. The strength of this static field at a point is defined as the force per unit charge on a stationary positive test charge, provided the test charge is so small that it does not disturb the original charge distribution.

electrostatic flux—The electrostatic lines of force existing between bodies at different potentials.

electrostatic focusing—The focusing of an electron beam by the action of an electric field.

electrostatic galvanometer — Galvanometer operated by the effects of two electric charges on each other.

electrostatic generator—A device for the production of electric charges by electrostatic action.

electrostatic induction—1. The process of charging an object electrically by bringing it near a charged object. 2. Capacitive induction of interfering signals over an air gap separating an instrument (e.g., from its wiring or housing).

electrostatic instrument — An instrument which depends for its operation on the attraction and repulsion between electrically charged bodies.

electrostatic memory—Also called electrostatic storage. A memory device in which information is retained by an electrostatic charge. A special type of cathode-ray tube is usually employed, together with associated circuitry.

electrostatic memory tube—Also called storage tube. An electron tube in which information is retained by electric charges.

electrostatic microphone—Also called capacitor or condenser microphone. A microphone which depends for its operation on variations in its electrostatic capacitance.

electrostatic precipitation—The process of removing smoke, dust, and other particles from the air by charging them so that they can be attracted to and collected by a properly polarized electrode.

electrostatic process — A reproduction method in which image formation depends on electrical rather than chemical changes induced by light.

electrostatic recording—Recording by means of a signal-controlled electrostatic field.

electrostatic relay—A relay in which two or more conductors that are separated by insulating material move because of the mutual attraction or repulsion produced by electric charges applied to the conductors.

electrostatics—The branch of physics concerned with electricity at rest.

electrostatic separator — An apparatus in which a finely pulverized mixture of the materials to be separated is passed through the powerful electrostatic field between two electrodes.

electrostatic series—*See* Triboelectric Series.

electrostatic shield—A shield which prevents electrostatic coupling between circuits, but permits electromagnetic coupling.

electrostatic speaker—Also called capacitor or condenser speaker. A speaker in which the mechanical forces are produced by the action of electrostatic fields.

electrostatic storage — The storage of changeable information in the form of charged or uncharged areas usually on the screen of a cathode-ray tube.

electrostatic transducer—A transducer that consists of a capacitor, at least one plate of which can be set into vibration. Its operation depends on the interaction between its

electric field and a change in its electrostatic capacity.

electrostatic tweeter — A speaker with a movable flat metal diaphragm and a nonmovable metal electrode capable of reproducing high audio frequencies. The diaphragm is driven by the varying high voltages applied across it and the electrode.

electrostatic unit—An electric unit based primarily on the dynamic interaction of electric charges. Defined as a charge which, if concentrated on a small sphere, would repel with a force of one dyne a similar charge one centimeter away in a vacuum.

electrostatic voltmeter — A voltmeter depending for its action on electrostatic forces. Its scale is usually graduated in volts or kilovolts.

electrostatography—The process of recording and reproducing visible patterns by the formation and utilization of latent electrostatic charge patterns.

electrostriction—A mechanical deformation caused by the application of an electric field to any dielectric material. The deformation is proportional to the square of the applied field. This phenomenon results from the induced dipole movement caused by the applied field, resulting in the mechanical distortion.

electrostrictive effect—The elastic deformation of a dielectric by an electrostatic field.

electrostrictive relay—A relay the operation of which is produced by an electrostrictive-dielectric actuator.

electrotape — An electronic distance-measuring device.

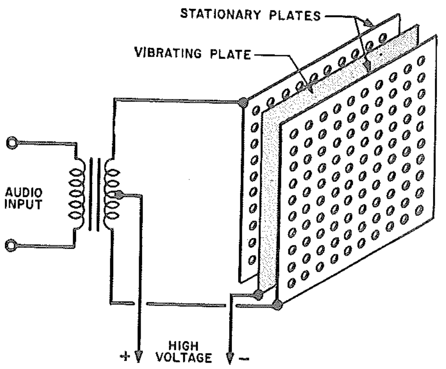
electrotherapeutics—*See* Electrotherapy.

electrotherapy—Also known as electrotherapeutics. The medical science or use of electricity to treat a disease or ailment.

electrotherapy apparatus — Equipment for applying electric current to the body for massage or heat treatment.

electrothermal—The heating effect of electric current, or the electric current produced by heat.

electrothermal expansion element—An actuating element consisting of a wire strip or



Electrostatic speaker.

other shape and having a high coefficient of thermal expansion.

electrothermal recorder — A recorder in which heat produces the image on the recording medium in response to the received signals.

electrothermal recording—*See* Electrothermal Recorder.

electrothermic instrument—An instrument which depends for its operation on the heating effect of a current. Examples are the thermocouple, bolometric, hot-wire, and hot-strip instruments.

electrothermics—The branch of science concerned with the direct transformation of electric energy into heat.

electrowinning—The process by which metals are recovered from a solution by electrolysis.

element—1. One of the 104 known chemical substances that cannot be divided into simpler substances by chemical means. A substance the atoms of which all have the same atomic number (e.g., hydrogen, lead, uranium). 2. In a computer, the portion or subassembly which constitutes the means of accomplishing one particular function, such as the arithmetic element. 3. Any electrical device (such as an inductor, resistor, capacitor generator, line, or electron tube) with terminals at which it may be connected directly to other electrical devices. 4. The dot or dash of an International Morse character. 5. A radiator, either active or parasitic, that is part of an antenna. 6. The smallest portion of a televised picture that still retains the characteristics of the picture. 7. A portion of a part that cannot be renewed without destruction of the part. 8. A constituent of a microcircuit or integrated circuit that contributes directly to its operation.

elemental area—*See* Picture Element.

elemental semiconductor—A semiconductor containing only one element in the undoped state.

elementary charge—A natural unit or quantum into which both positive and negative charges appear to be subdivided. It is the charge on a single electron and has a value of about 4.77×10^{-10} electrostatic units.

element error rate—The ratio of the number of elements incorrectly received to the total number of elements sent.

elevation—The angular position perpendicular to the earth's surface.

elevation-position indicator—A radar display which simultaneously shows angular elevation and slant range of detected objects.

elevator leveling control — A positioning control used to align the platform of an elevator with the floor level of the building. Metal vanes are mounted in the elevator shaft at each floor level, and an oscillator is mounted on the elevator car. When the elevator is properly leveled, the metal vane is between the plate and the grid coils of the oscillator. A relay connected in the oscillator circuit now energizes. The contacts of

this relay are connected in the motor-control circuit of the elevator so that the elevator stops in alignment with the floor level.

elf — Abbreviation for extremely low frequency.

eliminator—Also called a battery eliminator. A device operated from an a-c or d-c power line and used for supplying direct current and voltage to a battery-operated circuit.

elliptically polarized wave—An electromagnetic wave the electric intensity vector of which describes an ellipse at one point.

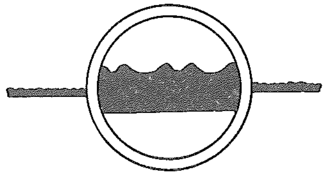
elliptical polarization—Polarization in which the wave vector rotates in an elliptical orbit about a point.

e/m—The ratio of the electric charge to the mass for particles such as electrons and positive rays. For slow-moving electrons, the value of e/m is 1.77×10^4 coulombs per gram. The value decreases with increasing velocity, however, because of an increase in effective mass.

embedding—A general term for all methods of surrounding or enclosing components and assemblies with a substantial thickness of electrically insulating solid or foam material that substantially fills the voids or interstices between parts.

embedment—The complete encasement of a part or assembly to some uniform external shape. A relatively large volume of a complete package consists of the embedment material.

embossed-foil printed circuits—A printed circuit formed by indenting the desired pattern of metal foil into an insulating base, and then mechanically removing the remaining unwanted raised portion.



Embossed-groove recording.

embossed-groove recording—A method of recording sounds on discs or film strips by embossing sound grooves with a blunt stylus rather than by cutting into them with a sharp stylus. Embossing throws the material up in furrows on each side of the sound groove without actually removing any of the material in the disc or strip.

embossing stylus—A recording stylus with a rounded tip which forms a groove in the recording medium by merely displacing the material instead of removing it completely.

emergency communication — The transmission or reception of distress, alarm, urgent, or safety signals or messages relating to the safety of life or property, or the occasional operation of equipment to determine whether it is in working condition.

emergency radio channel—Any radio frequency reserved for emergency use, particularly for distress signals.

emergency service—The radio-communication service carrier used for emergency purposes.

emf—Abbreviation for electromotive force.

emission—1. The waves radiated into space by a transmitter. 2. The ejection of electrons from the surface of a material (under the influence of heat, for example).

emission characteristic — The relationship between the emission and the factor controlling it, such as temperature, voltage, or current of the filament or heater. This relationship is usually shown on a graph.

emission current—The current produced in the plate circuit of a tube when all the electrons emitted by the cathode pass to the plate.

emission efficiency—The rating of a hot cathode. Expressed in milliamperes per watt.

emission spectrum—The spectrum showing the radiation emitted by a substance, such as the light emitted by a metal when placed in an electric arc, or the light emitted by an incandescent filament.

emission types—The classification of modes of radio transmission adopted by international agreement. The a-m designations are:

Type A0. Unmodulated continuous-wave transmission.
Type A1. Telegraphy or pure continuous waves.
Type A2. Modulated telegraphy.
Type A3. Telephony.
Type A4. Facsimile.
Type A5. Television.

emission-type tube tester — Also called an English-reading tube tester. A tube tester for checking the electron emission from the filament or cathode. The indicating meter is generally calibrated to read "Good" or "Bad." The tester connects all elements such as the plate and screen, suppressor, and control grids together and uses them as an anode.

emission velocity—The initial velocity at which electrons emerge from the surface of a cathode, ranging from zero up to a few volts (attained by very few electrons). This effect accounts for the existence of virtual cathodes, and also for the shape of the cutoff region of plate current.

emissivity—The ratio of the radiant energy emitted by a radiation source to the radiant energy of a perfect (black-body) radiator having the same area and at the same temperature and conditions.

emitron — A cathode-ray tube developed in England.

emitron camera—A British television camera tube resembling an iconoscope.

emittance—The power per unit area radiated by a source of energy.

emitter—1. An electrode within a transistor from which carriers are usually minority carriers; when they are majority carriers, the emitter is referred to as a majority emitter. 2. Of a transistor, a region from which charge carriers that are minority carriers in the base are injected into the base. 3. A device used on a punched-card machine to give timed pulses at regular intervals during the machine cycle.

emitter bias—The bias voltage applied to the emitter of a transistor.

emitter current—The direct current flowing in the emitter circuit of a transistor.

emitter follower—A common-collector transistor amplifier similar in operation to a vacuum-tube cathode follower.

emitter-follower amplifier — *See* Common-Collector Amplifier.

emitter junction—A semiconductor junction normally biased in the low-resistance direction so that minority carriers are injected into the interelectrode region.

emitter (junction transistor)—In a double-junction (PNP or NPN) transistor, the end semiconductor material that is forward-biased with respect to the base and emits a flow of carriers into the interelectrode region. Roughly comparable to the cathode of a tube.

emitter resistance—The resistance in series with the emitter lead in the common-T equivalent circuit of a transistor.

emitter semiconductor — A junction normally biased in the low-resistance direction to inject minority carriers into an interelectrode region.

emitter voltage—The voltage between the emitter terminal and a reference point.

empire cloth—A cotton or linen cloth coated with varnish and used as insulation on coils and other parts of electrical equipment.

empirical—Based on actual measurement, observation, or experience, as opposed to theoretical determination.

emu—Abbreviation for electromagnetic unit.

enable—To permit a circuit to be activated by the removal of a suppression signal.

enabling gate—A circuit which determines the start and length of a generated pulse.

enabling pulse—A pulse which opens a normally closed electric gate, or otherwise permits an operation for which a pulse is a necessary condition.

enameled wire—Wire coated with a layer of baked-enamel insulation.

encapsulating material—A composition primarily adapted for use on or around an electrical device to provide protection from the surrounding environment.

encapsulation—A protective coating of cured plastic placed around delicate electronic components and assemblies. It is identical to potting, except the cured plastic is removed from the mold. The plastic therefore determines the color and surface hardness of the finished part. The molds may be made of any suitable material.

enclosed relay — A relay in which both the coil and the contacts are protected from the environment.

enclosure—A housing for any electrical or electronic device, normally a speaker.

encode—Also called encipher; the inverse of decode. Conversion of signals to coded form. A circuit that generally converts signals from decimal to binary form.

encoder—1. An electromechanical device that can be attached to a shaft to produce a series of pulses to indicate shaft position; when the output is differentiated, the device is an accurate tachometer. (It is fundamentally oriented to digital rather than analog techniques.) An encoder contains a disc with a printed pattern; as the disc rotates, it makes and breaks a circuit. The more make-and-break cycles per revolution, the better the resolution. 2. A digital-to-analog converter.

end-around shift—In a computer, the movement of characters from one end of the register to the other end of the same register.

end bell—An accessory which is similar to a cable clamp and attaches to the back of a plug or receptacle. It serves as an adapter for the rear of connectors. Some angular end bells have built-in cable clamps. Angular end bells up to 90° are available.

end bracket—*See* End Shield.

end effect—The capacitive effect at the ends of a half-wave antenna. To compensate for this effect, a dipole is cut slightly shorter than a half wave.

end-fire array—A linear or cylindrical antenna having its direction of maximum radiation parallel to the long axis of the array.

end instrument—A device connected to one terminal of a loop and capable of converting usable intelligence into electrical signals, or vice versa. Includes all generating, signal-converting, and loop-terminating devices at the transmitting and/or receiving location.

end item—A combination of products, parts, and/or materials that is ready for its intended use.

end mark—In a computer, a code or signal used to indicate the termination of a unit of information.

endodyne reception—A British term applying to reception of unmodulated code signals. A vacuum-tube circuit having a local oscillator whose frequency is slightly different from that of the carrier signal. Thus a beat signal in the audio range is produced.

end-of-file mark—In a computer, a code instruction indicating that the last record of a file has been read.

end-on armature—Of a relay, an armature which moves in the direction of the core axis, with the pole face at the end of the core and perpendicular to this axis.

end-on directional antenna—A directional antenna which radiates chiefly toward the line on which the antenna elements are arranged.

endoradiosonde—Also called radio pill. A device for detecting and transmitting physiological data from the gastrointestinal tract or other inaccessible body cavities.

endothermic—A term describing a chemical reaction in which heat is absorbed.

end point—The shaft positions immediately before the first and after the last measurable change(s) in output ratio after wiper continuity has been established, as the shaft of a precision potentiometer moves in a specified direction.

end-point sensitivity—The algebraic difference in electrical output between the maximum and minimum value of the measurand over which an instrument is calibrated.

end-point voltage—The terminal voltage of a cell below which equipment connected to it will not operate or should not be operated.

end resistance—The resistance of a precision potentiometer measured between the wiper terminal and an end terminal, with the shaft positioned at the corresponding end point.

end-resistance offset — In potentiometers, the residual resistance between a terminal and the moving contact, at a position corresponding to full rotation against that terminal.

end scale value—The value of the actuating electrical quantity that corresponds to end scale indication of an instrument. When zero is not at the end or at the electrical center of the scale, the higher value is taken. Certain instruments such as power-factor meters, ohmmeters, etc., are necessarily excepted from this definition.

end setting—In a potentiometer, the minimum resistance that is measured between one end of a potentiometer and the wiper, with the wiper mechanically positioned at that end.

end shield—1. Frequently called end bracket or end bell. In a motor housing, the part that supports the bearing and also guards the electrical and rotating parts inside the motor. 2. In a magnetron, the shield that confines the space charge to the interaction space.

end spaces—In a multicavity magnetron, the two cavities at either end of the anode block which terminate all the anode-block cavity resonators.

end use — The way the ultimate consumer uses a device.

energize—To apply the rated voltage to a circuit or device, such as to the coil of a relay, in order to activate it.

energized—Also called alive, hot, and live. Electrically connected to a voltage source.

energy—The capacity for performing work. A particle or piece of matter may have energy because it is moving or because of its position in relation to other particles or pieces of matter. A rolling ball is an example of the first; a ball at rest at the top of an incline, an example of the second.

energy conversion — The change of energy from one form to another, e.g., from chemical energy to electrical energy.

energy conversion devices—Devices including primary and secondary cells; fuel cells;

photovoltaic systems; electrochemical energy converters; radiation conversion devices; thermionic converters; converters using solar, ionic, or nuclear energy sources; devices for creating a plasma in an interaction space between an emitter and a collector; electrostatic generators for creating an electrical output; organic and inorganic ion exchange and membrane devices; electron-volt energy devices; devices for direct conversion of fuel to electricity; and electrical-energy storage-unit devices capable of delivering a power output.

energy density—The ratio of the energy available from a cell to the weight or volume of the cell.

energy gap—The energy range between the bottom of the conduction band and the top of the valence band of a semiconductor.

energy-level diagram—A line drawing that shows the increase or decrease in electrical power as current intensities rise and fall along a channel of signal communications.

energy-measuring equipment—Equipment used to measure energy in electrical, electronic, acoustical, or mechanical systems.

energy of a charge—Represented by $E = \frac{1}{2}QV$, given in ergs, when the charge Q and the potential V are in electrostatic units.

energy-product curve—A curve obtained by plotting the product of the value of magnetic induction B and demagnetizing force H for each point of the demagnetization curve of a permanent magnetic material. Usually shown together with the demagnetization curve.

energy redistribution—A method of finding the duration of an irregularly shaped pulse by considering it as a power curve. The area under the curve can be represented by an equivalent rectangle of the same area and peak amplitude. The original-pulse duration is equal to the rectangle width.

energy state—The position and speed of an electron relative to the position and speed of other electrons in the same atom or adjoining atoms.

engineering—A profession in which a knowledge of the natural sciences is applied with judgment to develop ways of utilizing the materials and forces of nature.

English-reading tube tester—*See* Emission-Type Tube Tester.

enhanced carrier demodulation—An amplitude-demodulation system in which a synchronized local carrier of the proper phase is added to the demodulator. This has the effect of materially reducing the distortion produced in the demodulation process.

entropy—1. A measure of the unavailable energy in a thermodynamic system. 2. The unavailable information in a set of documents. 3. An inactive or static condition (total entropy).

entry—Each statement in a computer programming system.

envelope—1. The glass or metal housing of a vacuum tube. 2. The curve passing through the peaks of a graph and showing the waveform of a modulated radio-frequency carrier signal.

envelope delay—The time which elapses as a transmitted wave passes any two points of a transmission circuit. Such delay is determined primarily by the constants of the circuit and is measurable in milliseconds or microseconds.

envelope-delay distortion—The distortion that occurs during transmission when the phase shift of a circuit or system is not constant over the frequency range.

environmental conditions—External conditions of heat, shock, vibration, pressure, moisture, etc.

environmentally sealed—Provided with gaskets, seals, potting, or other means to keep out contamination which might reduce performance.

environmental testing—The testing of a system or component under controlled environmental conditions, each of which tends to affect its operation or life.

environmentproof switch—A switch which is completely sealed to insure constant operating characteristics. Sealing normally includes an "O" ring on the actuator shaft and fused glass-to-metal terminal seals or complete potting and an elastomer plunger-case seal.

episcotister—A device consisting of alternate opaque and transparent discs which rotate at a speed which interrupts light beams at an audio-frequency rate. It modulates the light beam used to excite a photoelectric element.

epitaxial—Pertaining to a single crystal layer on a crystalline substrate, oriented the same as the substrate. In certain semiconductor processes, an epitaxial layer is grown on a silicon substrate during the fabrication of transistors and integrated circuits.

epitaxial device—A device constructed in such a manner that the crystalline structure of successive layers is oriented in the same direction as that of the original base material.

epitaxial film—1. A film of single-crystal semiconductor material that has been deposited onto a single-crystal substrate. 2. Any deposited film, provided the orientation of its crystal is the same as that of the substrate material.

epitaxial growth—A chemical reaction in which silicon is precipitated from a gaseous solution, and grows on the surface of a silicon wafer present in the gaseous solution.

epitaxial-growth mesa transistor—A transistor made by overlaying a thin mesa crystal over another mesa crystal.

epitaxial growth process—The process of growing a semiconductor material by depositing it in vaporized form on a semiconductor seed crystal. The deposited layer continues the single-crystal structure of the seed.

epitaxial layer—A grown or deposited crystal layer with the same crystal orientation as the parent material and, in the case of semiconductor circuits, is also the same basic material as the original substrate.

epitaxial planar transistor—A transistor in which a thin collector region is epitaxially deposited on a low-resistivity substrate, and the base and emitter regions are produced by gaseous diffusion with the edges of the junction under a protective oxide mask.

epitaxial process—The process of growing from the vapor phase a single-crystal semiconductor material with controlled resistivity and thickness.

epitaxial transistor—A transistor with one or more epitaxial layers.

epitaxy—The controlled growth of a layer of semiconductor material in a suitable substrate.

E plane—The plane of an antenna containing the electric field. The principal E plane also contains the direction of maximum radiation.

E-plane bend—Also called E-bend. The smooth change in direction of the axis of a waveguide. The axis remains parallel to the direction of polarization throughout the change.

E-plane T-junction—Also called series T-junction. A waveguide T-junction in which the structure changes in the plane of the electric field.

epoxy resin—An insulating plastic used for encapsulating or embedding electronic equipment.

epsilon—The greek letter E, or ε, frequently used to represent 2.71828, which is the base of the natural system of logarithms.

equal-energy source—A light source having a constant emission rate of energy per unit of wavelength throughout the visible spectrum.

equal-energy white—The light produced by a source which radiates equal energy at all visible wavelengths.

equalization—The process of reducing the frequency and/or phase distortion of a circuit by the introduction of networks to compensate for the difference in attenuation and/or time delay at the various frequencies in the transmission band.

equalizer—1. A passive device designed to compensate for an undesired amplitude-frequency and/or phase frequency characteristic of a system or component. 2. A network having an attenuation complementary to that of a telephone line and inserted for the purpose of correcting frequency distortion caused by the line. 3. A network which improves the frequency response of a radio system. Usually a combination of resistors, inductors, and capacitors. 4. A series of connections made in paralleled, cumulatively compound direct-current generators to give the system stability.

equalizer circuit breaker—A breaker which serves to control or to make and break the equalizer or the current-balancing connections for a machine field, or for regulating equipment, in a multiple-unit installation.

equalizing current—A current circulated between two parallel-connected compound generators to equalize their output.

equalizing network—A network connected to a line to correct or control its transmission frequency characteristics.

equalizing pulses—A series of pulses (usually six) occurring at twice the line frequency before and after the serrated vertical tv synchronizing pulse. Their purpose is to cause vertical retrace to occur at the correct instant for proper interlace.

equal-loudness contours—*See* Fletcher-Munson Curves.

equation solver—A computer, usually of the analog type, designed to solve systems of linear simultaneous (nondifferential) equations or to find the roots of polynomials.

equiphase surface—In a wave any surface over which the field vectors at the same instant are either in phase or 180° out of phase.

equiphase zone—In radionavigation, the region in space within which the difference in phase between two radio signals is indistinguishable.

equipment—An item having a complete function apart from being a substructure of a system. Sometimes called a set.

equipment life—The arithmetic mean of the cumulative operating times of identical pieces of equipment beginning with the time of acceptance by the ultimate consumer and ending when the equipment is no longer serviceable.

equipotential—A conductor having all parts at a single potential. The cathode of a heater-type tube is equipotential, whereas the filament is not because its voltage varies from one end to the other.

equipotential cathode—*See* Indirectly Heated Cathode.

equipotential line—An imaginary line in space having the same potential at all points.

equipotential surface—A surface or plane passing through all points having the same potential in a field of flow.

equisignal localizer—Also called tone localizer. A type of localizer in which lateral guidance is obtained by comparing the amplitudes of two modulation frequencies.

equisignal radio-range beacon—A radio-range beacon used for aircraft guidance. It transmits two distinctive signals, which are received with equal intensity only in certain directions called equisignal sectors.

equisignal surface—The surface formed around an antenna by all points which have a constant field strength (usually measured in volts per meter) during transmission.

equisignal zone—In radionavigation, the region in space within which the difference in amplitude between two radio signals is indistinguishable.

equivalence—A logic operator having the property that if P is a statement, Q is a statement, R is a statement, etc., then the equivalence of P,Q,R . . . is true if and only if all statements are true or all statements are false.

equivalent absorption—The rate at which a surface will absorb sound energy, expressed in sabins. Defined as the area of a perfect absorption surface that will absorb the same sound energy as the given object under the same conditions.

equivalent binary digits—The number of binary digits equivalent to a given number of decimal digits or other characters.

equivalent circuit—An arrangement of common circuit elements with electrical characteristics, equivalent to those of a more complicated circuit or device.

equivalent circuit of a piezoelectric crystal unit—The electric circuit which has the same impedance as the unit in the frequency region of resonance. It is usually represented by an inductance, capacitance, and resistance in series, shunted by the direct capacitance between the terminals of the crystal unit.

equivalent component density—In circuits where discrete components are not readily identifiable, the volume of the circuit divided by the number of discrete components necessary to perform the same function.

equivalent conductance—The normal conductance of an ATR tube in its mount, measured at its resonance frequency.

equivalent dark-current input—The incident luminous flux required to give an output current equal to the dark current.

equivalent differential input capacitance—The equivalent capacitance looking into the inverting or noninverting inputs of a differential amplifier with the opposite input grounded. *Also see* Equivalent Differential Input Impedance.

equivalent differential input impedance—The equivalent impedance looking into the inverting or noninverting input, with the opposite input grounded and the operational amplifier operated in the linear amplification region.

equivalent differential input resistance—The equivalent resistance looking into the inverting or noninverting input of a differential amplifier with the opposite input grounded. *Also see* Equivalent Differential Input Impedance.

equivalent diode—An imaginary diode consisting of the cathode of a triode or multigrid tube and a virtual anode to which is applied a composite controlling voltage of such a value that the cathode current would be the same as the current in the triode or multigrid tube.

equivalent four-wire system—A transmission system using frequency division to obtain full-duplex operation over only one pair of wires.

equivalent grid voltage—The grid voltage plus plate voltage, divided by the mu of the tube.

equivalent input offset current—The difference between the two currents flowing into the inverting and noninverting inputs of a differential amplifier when the output voltage is zero.

equivalent input offset voltage—The amount of voltage required at the input to bring the output to zero. Usually this voltage is adjustable to zero by using either a built-in or an external variable resistor (balance control).

equivalent input wideband noise voltage—The output noise voltage of a differential amplifier with the input shorted, divided by the d-c voltage gain of the amplifier. This voltage is measured with a true rms voltmeter and is limited to the combined bandwidth of the amplifier and meter.

equivalent height—The virtual height of an ionized layer of the ionosphere.

equivalent loudness—The intensity level of a sound relative to some arbitrary reference intensity, such as a 1000-hertz pure tone which is judged by the listeners to be equivalent in loudness.

equivalent network—A network which may replace another network without substantial change in the operation of the system.

equivalent noise input—In a photosensitive device, the value of incident luminous flux which produces an rms output current equal to the rms noise current within a specified bandwidth when the flux is modulated in a stated manner.

equivalent noise pressure—*See* Transducer Equivalent Noise Pressure.

equivalent noise resistance—A measure of the residual noise output of a potentiometer while the slider is being actuated. (The residual noise consists of active components in the form of self-generated voltages arising in the slider contact interface, and passive components in the form of ohmic contact resistance at the point of slider contact.)

equivalent noise temperature—The absolute temperature at which a perfect resistor with the same resistance as the component would generate the same noise as the component at room temperature.

equivalent permeability—The relative permeability which a component would have under specified conditions if it had the same reluctance as a component of the same shape and size but different materials.

equivalent plate voltage—The plate voltage plus mu times the grid voltage.

equivalent resistance—The concentrated or lumped resistance that would cause the same power loss as the actual small resistances distributed throughout a circuit.

equivalent series resistance—In a circuit, the square root of the difference between the impedance squared and the reactance squared.

equivocation—In a computer, the conditional information contained in an input symbol given an output symbol, averaged over all input-output pairs.

erasable storage—Storage media in a computer which holds information that can be changed.

erase—To replace all the binary digits in a storage device by binary zeros. In a binary computer, erasing is equivalent to clearing, while in a coded decimal computer where the pulse code for decimal zero may contain binary ones, clearing leaves decimal zero while erasing leaves all-zero pulse codes in all storage locations.

erase oscillator—In a magnetic recorder an oscillator that provides the high-frequency signal necessary for erasing a magnetic tape.

erasing head—A device for obliterating any previous recordings. It may also be used to precondition magnetic media for recording purposes.

erasing speed—In charge-storage tubes, the rate of erasing successive storage elements.

erasure—A process by which a signal recorded on a tape is removed and the tape made ready for rerecording. This may be accomplished by a-c erasure, where the tape is demagnetized by an alternating field which is reduced in amplitude from an initially high value, or by d-c erasure, where the tape is saturated by applying a primarily unidirectional field.

E-region—The region of the ionosphere about 50 to 100 miles above the earth's surface.

$E_r - E_y$—The resultant color television signal when E_y is subtracted from the original full red signal.

erg—The absolute centimeter-gram-second unit of energy and work. The work done when a force of one dyne is applied through a distance of one centimeter.

error—1. In mathematics, the difference between the true value and a calculated or observed value. A quantity (equal in absolute magnitude to the error) added to a calculated or observed value to obtain the true value is called a correction. 2. In a computer or data-processing system, any incorrect step, process, or result. In addition to the mathematical usage in the computer field, the term also commonly refers to machine malfunctions, or "machine errors," and to human mistakes, or "human errors."

error-correcting code—A code in which each acceptable expression conforms to specific rules of construction that also define one or more equivalent nonacceptable expressions, so that if certain errors occur, in an acceptable expression the result will be one of its equivalents and thus the error can be corrected.

error-correction routine—A series of computer instructions programmed to correct a detected error condition.

error detecting and feedback system—A system employing an error-detecting code and so arranged that a signal detected as being in error automatically initiates a request for retransmission of the signal detected as being in error.

error-detecting code—In a digital computer, a system of coding characters such that any single error produces a forbidden or impossible code combination.

error detector—That portion of an automatic control system that determines when the regulated quantity has deviated outside the dead zone.

error-rate damping—A damping method in which a signal proportional to the rate of change of error is added to the error signal for anticipatory purposes.

error signal—In an automatic control device, a signal whose magnitude and sign are used to correct the alignment between the controlling and the controlled elements.

error tape—A special tape developed and used for writing out errors in order to correct them by study and analysis after printing.

error voltage—A voltage which is present in a servo system when the input and output shafts are not in correspondence. The error voltage, which actuates the servo system, is proportional to the angular displacement between the two shafts.

Esaki diode—*See* Tunnel Diode.

E-scape—A radar display in which targets appear as blips, with distance indicated by the horizontal coordinate and elevation by the vertical coordinate.

escapement—A mechanical stepping device that stores energy over a predetermined time interval and delivers this stored energy at the end of said time interval to advance or move a camshaft a predetermined number of degrees.

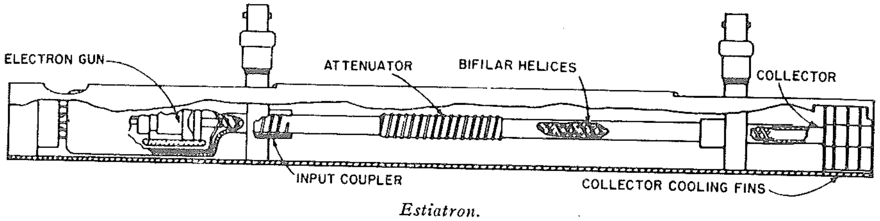
escape velocity—The speed which a particle or larger body must attain in order to escape from the gravitational field of a planet or star.

escutcheon—A backing plate around an opening. Commonly, the ornamental metal, wood, plastic, or other framework around a radio tuning dial, control knob, or other panel-mounted part in a radio receiver or television receiver, audio-frequency amplifier, etc.

Estiatron—A special type of electrostatically focused traveling-wave tube.

etchant—In the preparation of a printed-circuit board, a solution used to remove the unwanted portion of the conductive material by means of a chemical reaction.

etched printed circuit—A type of printed circuit formed by chemically or electrolytically (or both) removing the unwanted portion of a layer of material bonded to a base.



Estiatron.

etching to frequency—Finishing a crystal blank to its final frequency by etching it in hydrofluoric acid.

ether—A hypothetical medium that pervades all space (including vacuum) and all matter and is assumed to be the vehicle for propagation of electromagnetic radiations.

E transformer—A special form of differential transformer employing an E-shaped core. The secondaries of the transformer are wound on the outer legs of the E, and the primary is on the center leg.

Ettingshausen effect—Analogous to the Hall effect. The different temperatures found on opposite edges of a metal strip which is perpendicular to a magnetic field and through which an electric current flows longitudinally.

eureka—The ground transponder of secondary radar system rebecca-eureka.

ev or eV—Abbreviation for electron volt.

evaporation of electrons—The cooling which occurs on the surface of a cathode during emission. It is analogous to the cooling of a liquid or solid as it evaporates.

E-vector—A vector representing the electric field of an electromagnetic wave. In free space it is perpendicular to the direction of propagation.

even harmonic—Any harmonic that is an even multiple (2, 4, 6, etc.) of the fundamental frequency.

E-wave—Designation for TM (transverse magnetic) wave, one of the two classes of electromagnetic waves that can be sent through waveguides.

exalted-carrier receiver—A receiver that counteracts selective fading by maintaining the carrier at a high level at all times.

exalted-carrier reception—A method of receiving either amplitude- or phase-modulated signals in which the carrier is separated from the sidebands, filtered and amplified, and then recombined with the sidebands at a higher level prior to demodulation.

except gate—A gate in which the specified combination of pulses producing an output pulse is the presence of a pulse on one or more input lines and the absence of a pulse on one or more other input lines.

excess conduction—Conduction by excess electrons in a semiconductor.

excess electron—An electron introduced into a semiconductor by a donor impurity and available to promote conduction. An excess electron is not required to complete the bond structure of the semiconductor.

excess fifty—In a computer, a representation in which a number (N) is denoted by the equivalent of (N + 50).

excess meter—An electricity meter which measures and registers the integral, with respect to time, of those portions of the active power in excess of the predetermined value.

excess minority carriers—In a semiconductor, the number of minority carriers that exceed the normal equilibrium number.

excess modified index of refraction—*See* Refractive Modulus.

excess noise—Noise resulting from the passage of current through a semiconductor material. Also called current noise, bulk noise, and 1/f noise.

excess sound pressure—The total instantaneous pressure at a point in a medium containing sound waves, minus the static pressure when no sound waves are present. The unit is the dyne per square centimeter.

excess-three code—A number code in which the decimal digit N is represented by the four-bit binary equivalent of n + 3. (*Also see* Binary-Coded Decimal.)

exchange—To remove the contents of one storage unit of a computer and place it in a second, at the same time placing the contents of the second storage unit into the first.

exchange register—*See* Memory Register.

excitation—1. Also called stimulus. An external force or other input applied to a system to cause it to respond in some specified way. 2. Also called drive. A signal voltage applied to the control electrode of an electron tube. 3. In electric or electromagnetic equipment, supplying with a potential, a charge, or a magnetic field. 4. The addition of energy to a system so as to transfer the system from its ground state to an excited state.

excitation anode—An auxiliary anode of a pool-cathode tube, used to maintain a cathode spot when the output current is zero.

excitation current—The resultant current in the shunt field of a motor when voltage is applied across the field.

excitation energy—The external electrical energy required for proper operation of a transducer.

excitation purity—Also called purity. The ratio between the distance from the reference point to the point representing the sample and the distance along the same straight line from the reference point to the spectrum locus or to the purple boundary, both distances being measured (in the

same direction from the reference point) on the CIE chromaticity diagram.

excitation voltage—The voltage required for excitation of a circuit.

excited-field speaker—A speaker in which the steady magnetic field is produced by an electromagnet.

exciter—1. In a directional transmitting antenna system, the part connected directly to the source of power such as to the transmitter. 2. A crystal or self-excited oscillator that generates the carrier frequency of a transmitter. 3. A small, auxiliary generator that provides field current for an a-c generator.

exciter lamp—1. A high-intensity incandescent lamp having a concentrated filament. It is used in making variable-area, sound-on-film recording and in reproducing all types of sound tracks on film, as well as in some mechanical television systems. 2. A light source used in a facsimile transmitter to illuminate the subject copy being scanned.

exciter or d-c generator relay—A device which forces the d-c machine-field excitation to build up during starting, or which functions when the machine voltage has built up to a given value.

exciting current—1. The current which flows in the primary of a transformer when the secondary is open-circuited. This current produces a flux that generates a back emf equal to the applied voltage. 2. Also called magnetizing current. The current that passes through the field windings of a generator.

exciting current of a transformer—Also called no-load current. The current used in any winding to excite the transformer when all other windings are open-circuited, usually expressed in percent of the rated current of the windings in which it is measured.

exciton—A bound electron-hole pair in an insulator or a semiconductor. It may move through the crystal transporting excitation energy, but does not contribute to electric conductivity since it is neutral.

excitron—A single-anode pool tube with means for maintaining a continuous cathode spot.

exclusion principle—The principle which states that if particles are considered to occupy quantum states, then only one particle of a given kind can occupy any one state. Particles differ in kind due to their direction of spin, momentum, orbit, etc.

exclusive OR—A logic element with two inputs and one output. The output is true if either of the two inputs is true, but *not* if both are true.

excursion—A single movement away from the mean position in an oscillating or alternating motion.

execution—The performance of an operation or instruction.

executive routine—In digital-computer programming, a routine designed to process and control other routines.

exhaustion—The removal of gases from a space, such as the bulb of a vacuum tube, by means of vacuum pumps.

exit—In a computer, the means of halting a repeated cycle of operation in a program.

exosphere—The outermost region of the earth's atmosphere, where the atoms and molecules move in dynamic orbits under the influence of the gravitational field.

exothermic—A chemical reaction in which heat is produced.

expand—To spread out part or all the trace of a cathode-ray display.

expanded scale meter—A meter in which the ratio of deflection per unit of applied energy becomes greater as the energy approaches a specified value.

expanded scope—A magnified portion of a cathode-ray-tube presentation.

expanded sweep—A preselected portion of a sweep, during which time the electron beam is speeded up in a cathode-ray tube.

expander—A transducer which produces a larger range of output voltages for a given amplitude range of input voltages. One important type expands the volume range of speech signals by employing their envelope.

expansion—A process in which the effective gain applied to a signal is increased for larger signals and decreased for smaller signals.

experimental model—An equipment model that demonstrates the technical soundness of a basic idea but does not necessarily have the same form or parts as the final design.

experimental station—Any station (except amateur) utilizing electromagnetic waves between 10 kHz and 3000 GHz in experiments, with a view toward the development of a science or technique.

exploring coil—*See* Magnetic Test Coil.

explosion-proof motor—A motor designed and constructed so as to withstand an internal explosion of a specified gas or vapor and to prevent the ignition of the specified gas or vapor surrounding the motor by sparks, flashes, or explosions of the specified gas or vapor inside the motor casing.

explosive atmosphere—The condition where air is mixed with dust, metal particles, or inflammable gas in such proportion that it is capable of igniting or exploding.

exponential—Pertaining to exponents or to an expression having exponents. A quantity that varies in an exponential manner increases by the square or some other power of a factor, instead of linearly.

exponential curve—A curve representing the variation of an exponential function.

exponential damping—Damping which follows an exponential law.

exponential decay—The decay of signal strength, radiation, charge, or some other quantity at an exponential rate.

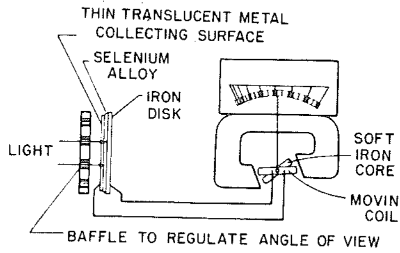
exponential horn—A horn the cross-sectional area of which increases exponentially with axial distance.

exponential quantity—A single quantity which increases or decreases at the same rate as the quantity itself (e.g., the discharge current of a capacitor through a noninductive resistor).

exponential sweep—An electron-beam sweep which starts rapidly and slows down exponentially.

exponential transmission line—A two-conductor transmission line the characteristic impedances of which vary exponentially with the electrical length of the line.

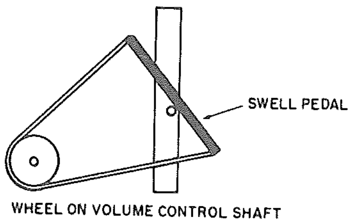
exponential waveform—A waveform which is characterized by smooth curves but which possesses pulse properties because it contains numerous constituent frequencies. The exponential waveform undergoes a rate of amplitude change which is either inversely or directly proportional to the instantaneous amplitude.



THIN TRANSLUCENT METAL COLLECTING SURFACE
SELENIUM ALLOY
IRON DISK
LIGHT
SOFT IRON CORE
MOVING COIL
BAFFLE TO REGULATE ANGLE OF VIEW

Exposure meter.

exposure meter—In photography, an instrument which measures scene brightness and indicates proper lens opening and exposure time.



Expression control.

expression control—In an organ the control which regulates the over-all volume. Usually operated with the right foot.

extended-cutoff tube—*See* Remote-Cutoff Tube.

extended octaves—In an organ, tones above or below the notes on the regular keyboard which can be sounded only when certain couplers are on.

extended play—Abbreviated ep. A 45-rpm record on a seven-inch disc. It provides eight minutes of playing time, instead of the five minutes of a standard 45-rpm disc.

external armature—A ring-shaped armature that rotates around the field magnets of a generator or motor.

external circuit—All wires and other conductors which are outside the source.

external control devices—All control devices mounted external to the control panel.

external critical damping resistance—The value of resistance that must be placed in series or in parallel with a galvanometer in order to produce the critically damped condition.

external feedback—In a magnetic amplifier, the ampere-turns of auxiliary windings which assist in equalizing the load winding ampere-turns, thereby reducing the control ampere-turns required for control. External feedback may be degenerative to reduce the gain and improve the stability of an amplifier.

externally adjustable timer—A time delay which can be adjusted by varying the resistance of the timer resistor externally, usually by means of a screwdriver.

externally caused contact chatter—That chatter resulting from shock or vibration imposed on the relay by external action.

externally caused failure—A failure caused by an environment outside the design limitations, such as excessive loads, voltages, etc., resulting from operator error, accident, or failure of another part.

externally quenched counter tube—A radiation counter tube that requires an external circuit to prevent it from reigniting.

external memory—A storage unit outside the computer (e.g., a magnetic tape).

external Q—In a microwave tube, the reciprocal of the difference between the reciprocal of the loaded Q and the reciprocal of the unloaded Q.

external storage—Storage facilities separate from the computer itself but holding information in a form acceptable to the computer, e.g., magnetic tapes, magnetic wires, punched cards, etc.

extinction potential—The lowest value to which the plate voltage of a gaseous tube can be reduced without cutting off the flow of plate current.

extra-class license—The highest classification of United States amateur license. Requirements include a code sending and receiving ability of 20 words per minute, a knowledge of advanced theory, and the holding of a general- or conditional-class license for two years.

extract—To remove from a set of items of information all those items that meet some arbitrary criterion.

extract instruction—In a digital computer, the instruction to form a new word by placing selected segments of given words side by side.

extractor—*See* Filter.

extraneous response—Any undesired response of a receiver, recorder, or other susceptible device, due to the desired signals, undesired signals, or any combination or interaction among them.

extraordinary wave component—The magnetoionic wave component in which the electric vector rotates in the opposite sense from that for the ordinary wave component.

extrapolate—To estimate the value of a function for variables lying outside the range in which values of the function are known (e.g., to extend the graphs of the function beyond the plotted points).

extremely high frequency—Abbreviated ehf. The frequency band extending from 30 to 300 GHz.

extremely low frequency—A frequency below 300 hertz. Abbreviated elf.

extrinsic base resistance-collector capacitance product—The product of the base resistance and collector capacitance of a transistor. It is expressed in units of time, since it is an RC time constant and affects the high-frequency operation of a transistor.

extrinsic conductance—The conductance resulting from impurities or external causes.

extrinsic properties—The properties of a semiconductor, modified by impurities or imperfections within the crystal.

extrinsic semiconductor—A semiconductor the electrical properties of which depend on its impurities.

eyelet—A tubular metal piece having one end (and possibly the second) headed or rolled over at a right angle.

F

f—1. Abbreviation for farad, femto (10^{-15}). 2. Symbol for focal length, frequency.

F—1. Symbol for filament, fuse. 2. Abbreviation for Fahrenheit.

F−—*See* A−.

F+—*See* A+.

fa—Abbreviation for femtoampere (10^{-15} ampere).

fabrication holes—*See* Pilot Holes.

fabrication tolerance—In the construction or assembly of an equipment or portion of an equipment, the maximum variation in the characteristics of a part which, considering the defined variations of the other parts in the equipment, will permit the equipment to operate within specified performance limits.

Fabry-Perot interferometer—A resonant cavity bounded by two end mirrors separated so as to produce interference for certain allowed optical frequencies. The enhancements and cancellations produced by the internal reflections are, in fact, optical standing waves. The structure can be used as a laser cavity, mode filter, or frequency selector.

face—1. A plane surface on a crystal which stands in a particular and invariable relation to the axes and planes of reference and to other faces. 2. Front, or viewing, surface of a cathode-ray tube. 3. The portion of a meter bearing the scale markings.

face bonding—A method of attaching active devices to thin-film passive networks. The semiconductor chips are provided with small mounting pads turned face down and bonded directly to the end of the thin-film conductors on the passive substrate.

faced crystal—A single or twinned mass of quartz bounded in part or entirely by the original crystal growth faces.

face-parallel cut—A Y-cut for a quartz crystal.

face-perpendicular cut—An X-cut for a quartz crystal.

facom—A long-distance measuring or radio-navigational system which derives information of distances by comparing the phases of received and locally generated signals. It is a base-line system operating in the low-frequency band and will work under adverse propagation and noise conditions at ranges of up to 3000 miles from the signal source.

facsimile—A process or the result of a process by which fixed graphic material including pictures or images is scanned and the information converted into electrical signal waves, which are used either locally or remotely to produce in record form a likeness (facsimile) of the subject copy.

facsimile broadcast station—A station licensed to transmit images of still objects for reception by the general public.

facsimile posting—The process of transferring, by a duplicating process, a printed line on a report to a ledger or other recorded sheet. These may be posted from a transaction listing previously prepared on an accounting machine. A data-processing function.

facsimile receiver—An apparatus that translates the facsimile signal into a reproduced image.

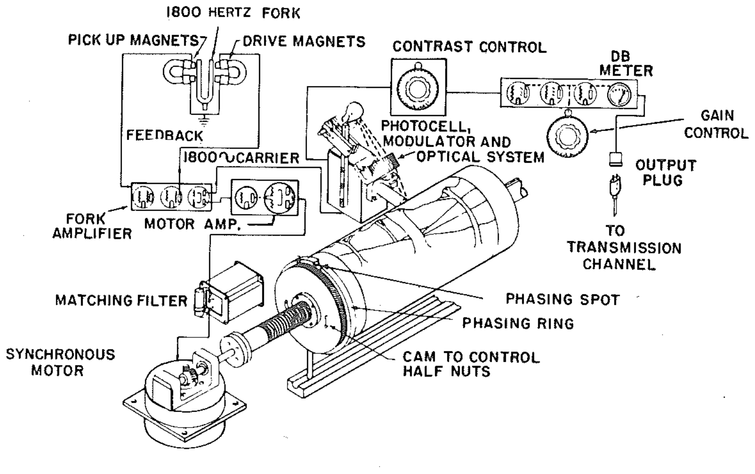
facsimile recorder—Apparatus which reproduces on paper the image transmitted by a facsimile system.

facsimile signal—The signal resulting from the scanning in a facsimile system.

facsimile-signal level—An expression of the maximum signal power or voltage created by the scanning of the subject copy as measured at any point in a facsimile system. According to whether the system employs positive or negative modulation, this will correspond to picture white or black, respectively. It may be expressed in decibels with respect to some standard value, such as 1 milliwatt or 1 volt.

facsimile system—An integrated assembly of the elements used for facsimile transmission and reception.

facsimile transmission—The transmission of signal waves produced by the scanning of a



Facsimile transmitter.

picture on a revolving drum by a photoelectric cell for reproduction in permanent form at the receiver.

facsimile transmitter—An apparatus employed to convert the subject copy into suitable facsimile signals. Usually, the copy is wrapped around a revolving drum and scanned by a photoelectric cell, which converts the darks and lights into corresponding signal amplitudes.

fade—The gradual lowering in amplitude of a signal.

fade in—To increase the signal strength gradually in a sound or television channel.

fade out—1. The gradual decrease in signal strength in a sound or television channel. 2. The cessation or near cessation of radio-wave propagation through parts of the ionosphere due to a sudden atmospheric disturbance.

fader—A multiple-unit control used in radio for gradual changeover from one microphone or audio channel to another; in television, from one camera to another; and in motion-picture projection, from one projector to another.

fading—The variation of radio field strength caused by a gradual change in the transmission medium.

fading margin—The number of decibels of attenuation which can be added to a specified radio-frequency propagation path before the signal-to-noise ratio of the channel falls below a specified minimum.

Fahnestock clip—A spring-type terminal to which a temporary connection can readily be made.

Fahrenheit temperature scale—A temperature scale in which the freezing point of water is defined as 32° and the boiling point as 212° under normal atmospheric pressure (760 mm of mercury).

fail hardover — Failure which results in a steady-state maximum system output with no input signal.

fail-safe circuit—A circuit that has an output state which indicates that either a circuit input or the circuit itself has failed. Finds application in complex systems where self-healing subsystems exist. When a subsystem failure is detected, a back-up subsystem is automatically inserted in its place.

fail-safe control—A system of remote control for preventing improper operation of the controlled function in event of circuit failure.

fail-safe operation—An electrical system so designed that the failure of any component in the system will prevent unsafe operation of the controlled equipment.

fail soft—An active failure which can be compensated for by the system or one where the operator can safely assume control.

failure—The inability of a system, subsystem, component, or part to function in the required or specified manner.

failure indicator—The observed characteristic that shows that an item is defective.

failure mechanism—*See* Failure Mode.

failure mode—The manner in which a failure occurs, including the operating condition of the equipment or part at the time of the failure. Also called failure mechanism.

failure rate—Also called hazard. The probability of failure, normally expressed in per cent per 1000 hours, of the items still operating.

fall-in—In a synchronous motor, the point at which synchronous speed is reached.

fallouts—*See* Transistor Seconds.

fall time—1. The length of time during which a pulse is decreasing from 90% to 10% of its maximum amplitude. 2. A measure of the time required for a circuit to change its output from a high level (1) to a low level (0).

false course—In navigation normally providing one or more course lines, a spurious additional course-line indication due to undesired reflections or maladjusted equipment.

false-echo device — A device for producing an echo different from that normally observed.

fan antenna—*See* Double-V Antenna.

fan beam—A field pattern having an elliptically shaped cross section in which the ratio of major to minor axes usually exceeds 3 to 1.

fan-in—The number of inputs that can be connected to a logic circuit.

fan-in circuit—A circuit that has many inputs feeding to a common point.

fan marker—A radio signal having a vertically directed fan beam which tells the pilot the location of his aircraft while flying along a radio range.

fanned-beam antenna—A unidirectional antenna so designed that transverse cross sections of the major lobe are almost elliptical.

fan-out — The number of parallel loads within a given logic family that can be driven from one output mode of a logic circuit.

fan-out circuit—A circuit that has a single output point which feeds many branches.

farad — The capacitance of a capacitor in which a charge of 1 coulomb produces a change of 1 volt in the potential difference between its terminals. The farad is the unit of capacitance in the mksa systems.

faraday—1. A unit equal to the number of coulombs (96,500) required for an electrochemical reaction involving one electrochemical equivalent. 2. In an electrolytic process, 1-gram equivalent weight of matter is chemically altered at each electrode for 1 faraday of electricity passed through the electrolyte.

Faraday cage—*See* Faraday Shield.

Faraday dark space—The relatively nonluminous region between the negative glow and the positive column in a glow-discharge–cold-cathode tube. (*Also see* Glow Discharge.)

Faraday effect—The rotation of the plane of polarization of radio waves as they pass through the ionosphere in the earth's magnetic field. This effect produces a decoupling loss between linearly polarized antennas.

Faraday rotation—The rotation of the plane of polarization of radiation when it passes through a plasma containing a magnetic field having a component in the direction of propagation.

Faraday screen—*See* Faraday Shield.

Faraday shield—Also called Faraday screen or Faraday cage. A network of parallel wires connected to a common conductor at one end to provide electrostatic shielding without affecting electromagnetic waves. The common conductor is usually grounded.

Faraday's laws—1. The mass of a substance liberated in an electrolytic cell is proportionate to the quantity of electricity passing through the cell. 2. When the same quantity of electricity is passed through different electrolytic cells, the masses of the substances liberated are proportionate to their chemical equivalents. 3. Also called the law of electromagnetic induction. 4. When a magnetic field cuts a conductor, or when a conductor cuts a magnetic field, an electric current will flow through the conductor if a closed path is provided over which the current can circulate.

faradic current—An intermittent and nonsymmetrical alternating current like that obtained from the secondary winding of an induction coil.

faradmeter—An instrument for measuring electric capacitance.

far-end cross talk—Cross talk which travels along the disturbed circuit in the same direction as the signals in that circuit. To determine the far-end cross talk between two pairs, 1, and 2, signals are transmitted on pair 1 at station A and the cross-talk level is measured on pair 2 at station B.

far field—The space beyond the near field of an antenna in which radiation is essentially confined to a fixed pattern and power density along the axis of the pattern falls off inversely with the square of the distance.

far-field region—That region of the field of an antenna where the angular field distribution is essentially independent of the distance from the antenna.

Farnsworth image-dissector tube—A special cathode-ray tube for use in television cameras.

fast-access storage—In a computer memory or storage, the section from which information may be obtained most rapidly.

fastener—A device used to secure a conductor (or other object) to the structure which supports it.

fast forward—The provision on a tape recorder permitting tape to be run rapidly through the recorder in the play direction, usually for search or selection purposes.

fast-forward control—A tape-recorder control which permits running the tape through the machine rapidly in the forward direction.

fast groove—Also called fast spiral. In disc recording, an unmodulated spiral groove having a much greater pitch than the recorded grooves.

fast-operate–fast-release relay — A high-speed relay designed specifically for both short-operate and short-release times.

fast-operate relay—A high-speed relay designed specifically for short-operate but not short-release time.

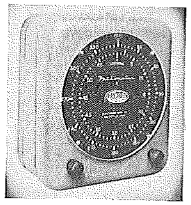
fast-operate–slow-release relay—A relay designed specifically for short-operate and long-release times.

fast-release relay—A high-speed relay designed specifically for short-release but not short-operate time.

fast spiral—*See* Fast Groove.

fast time constant—An antijamming device used in radar video-amplifier circuits. It differentiates incoming pulses so that only the leading edges of the pulse are used.

fathometer—Also called depth finder, depth sounder, acoustic depth finder, echo depth sounder, or sonic depth sounder. A direct-reading device for determining the depth of water in fathoms or other units by reflecting sonic or ultrasonic waves from the ocean bottom. Also used to locate underwater bodies, such as schools of fish or sunken objects.



Fathometer.

fatigue—The weakening of a material under repeated stress.

fault—A defect in a wire circuit due to unintentional grounding, a break in the line, or a crossing or shorting of the wires.

fault current—The current that may flow in any part of a circuit or amplifier under specified abnormal conditions.

fault electrode current—The peak current that flows through an electrode during a fault, such as an arc back or a load short circuit.

fault finder—A test set for locating troubles in a telephone system.

fault indicator—Equipment that provides an instantaneous alarm, both visual and audible, of failures detected in the various components of its assorted equipment.

Faure plate—A storage-battery plate consisting of a conductive lead grid filled with active paste material.

fax—Abbreviation for facsimile.

fc—Abbreviation for footcandle.

FCC—Abbreviation for Federal Communications Commission.

F-display—Also called F-scan or F-scope. In radar, a rectangular display in which a target appears as a centralized blip when the radar antenna is aimed at it. Horizontal and vertical aiming errors are indicated by the horizontal and vertical displacement of the blip.

fdm — Abbreviation for frequency-division multiplex.

Federal Communications Commission—Abbreviated FCC. A board of seven commissioners appointed by the President under the Communications Act of 1934, having the power to regulate all interstate and foreign electrical communication systems originating in the United States.

feedback—1. In a transmission system or a section of it, the returning of a fraction of the output to the input. 2. In a magnetic amplifier, a circuit connection by which an additional magnetomotive force (which is a function of the output quantity) is used to influence the operating condition. 3. Part of a closed-loop system which brings back information about the condition under control, for comparison with the target value.

feedback amplifier—An amplifier that uses a passive network to return a portion of the output signal to modify the performance of the amplifier.

feedback attenuation—In the feedback loop of an operational amplifier, an attenuation factor by which the output voltage is attenuated to produce the input error voltage.

feedback control—A type of system control obtained when a portion of the output signal is operated upon and fed back to the input in order to obtain a desired effect.

feedback control loop—A closed transmission path which includes an active transducer and consists of a forward path, a feedback path, and one or more mixing points arranged to maintain a prescribed relationship between the loop input and output signals.

feedback control signal — That portion of the output signal which is returned to the input in order to achieve a desired effect, such as fast response.

feedback control system—A control system comprising one or more feedback control loops; it combines the functions of the controlled signals and commands, tending to maintain prescribed relationship between the two.

feedback cutter—An electromechanical transducer which performs like a disc cutter except it is equipped with an auxiliary feedback coil in the magnetic field. Signals exciting the cutter are induced into the feedback coil, the output of which is fed back in turn to the input of the cutter amplifier. The result is a substantially uniform frequency response.

feedback oscillator—An oscillating circuit, including an amplifier, in which the output is coupled in phase with the input. The oscillation is maintained at a frequency determined by the parameters of the amplifier and the feedback circuits, such as LC, RC, and other frequency-selective elements.

feedback path—In a feedback control loop, the transmission path from the loop output signal to the loop feedback signal.

feedback regulator—A feedback control system which tends to maintain a prescribed relationship between certain system signals and other predetermined quantities.

feedback transfer function—In a feedback control loop, the transfer function of the feedback path.

feedback winding—In a saturable reactor, the control winding to which a feedback connection is made.

feeder—A conductor or group of conductors connecting two generating stations, two substations, a generating station and a substation or feeding point, a substation and a feeding point, or a transmitter and antenna.

feeder cable—1. A communication cable extending from the central office along a primary route (main feeder cable), or from a main feeder cable along a secondary route (branch feeder cable) and providing connections to one or more distribution cables. 2. Also called trunk cable. In a catv system, the transmission cable from the head end (signal pickup) to the trunk amplifier.

feed holes—A series of small holes in perforated paper tape which convey no information, but are solely for the purpose of engaging the feed pawls or sprocket which transports the tape over the sensing pins of various reading devices.

feed pitch—The distance between the centers of adjacent feed holes in a tape.

feed reel—On a tape recorder, the reel which supplies the magnetic tape to the recording or playback head.

feedthrough—1. The accidental or unintentional transfer of a signal from one track to another on a multitrack tape. 2. The use of special connectors to pass conductors through bulkheads or panels. Contacts can be male on one side and female on the other, or they can be male on both sides or female on both sides. Feedthrough connectors differ from rack-and-panel types in that connection can be made on both sides of the panel.

feedthrough capacitor — A feedthrough insulator that provides a desired value of capacitance between the feedthrough conductor and the metal chassis or panel through which the conductor is passing. Used chiefly for bypass purposes in uhf.

feedthrough insulator—A type of insulator which permits wire or cable to be fed through walls, etc., with minimum current leakage.

feed-thru connection — *See* Thru-hole Connection.

female—The recessed portion of a device into which another part fits.

femto — Prefix meaning 10^{-15}. Abbreviated f.

femtoampere — A unit of current equal to 10^{-15} ampere. Abbreviated fa.

femtovolt—A unit of voltage equal to 10^{-15} volt. Abbreviated fv.

Fermi level—The value of electron energy at which the Fermi distribution function is one half.

ferreed—An electromechanical switch that combines the rapid switching of bistable magnetic material with metallic contacts to produce output indications that persist as long as desired without further application of power.

ferret reconnaissance—A form of reconnaissance which detects, locates, and analyzes enemy radars. It is a passive technique that listens for signals transmitted by enemy radars and thus cannot be jammed. The maximum effective range is limited only by the radio horizon. Ferret systems flown at altitudes of a few miles can accurately locate and analyze radars 300 miles away. Ferret is the only all-weather reconnaissance technique, and no camouflage system works against a properly designed ferret.

ferri—Prefix indicating a material having a net dipole moment.

ferric oxide (Fe_2O_3) — A red, iron oxide coating for magnetic recording tapes.

ferrimagnetic amplifier—A microwave amplifier utilizing ferrite material in the coupling inductors and transformers.

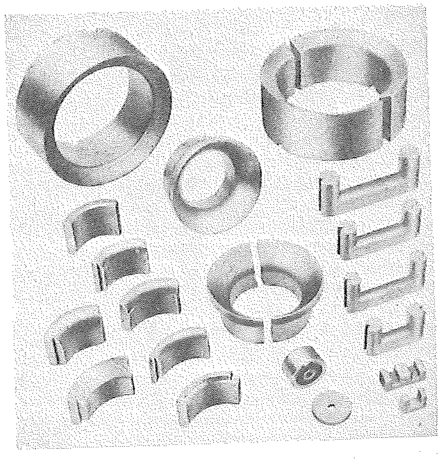
ferrimagnetic materials — Those materials in which spontaneous magnetic polarization occurs in nonequivalent sublattices; the polarization in one sublattice is aligned antiparallel to the other.

ferristor—A two-winding ferroresonant magnetic amplifier that operates on a high carrier frequency.

ferrite—Also called ferrospinel. A powdered, compressed, and sintered magnetic material having high resistivity, consisting chiefly of ferric oxide combined with one or more other metals. The high resistance makes eddy-current losses extremely low at high frequencies. Examples of ferrite compositions include nickel ferrite, nickel-cobalt ferrite, manganese-magnesium ferrite, yttrium-ion garnet, and single-crystal yttrium-ion garnet.

ferrite circulator — A nonreciprocal microwave network which transmits power from one terminal to another in sequence. Can replace a conventional duplexer, provide isolation of transmitter from receiver, eliminate the requirement for an ATR, and isolate the transmitter from antenna reflections.

ferrite core—A core made from iron and other oxides and usually shaped like a doughnut. It is used in circuits and magnetic memories and can be magnetized and demagnetized very rapidly.



Ferrite cores.

ferrite isolator—A device either in a waveguide or coax which allows power to pass through in one direction with very little loss, while the r-f power in the reverse direction is absorbed. It is useful for maintaining signal source stability and eliminating long-line and frequency-pulling effects in all types of low-power microwave signal sources.

ferrite-rod antenna—Also called ferrod or loopstick antenna. An antenna used in place of a loop antenna in a radio receiver. It consists of a coil wound around a ferrite rod.

ferrites—Chemical compounds of iron oxide and other metallic oxides combined with ceramic material. They have ferromagnetic properties but are poor conductors of electricity. Hence they are useful where ordinary ferromagnetic materials (which are good electrical conductors) would cause too great a loss of electrical energy.

ferrod—*See* Ferrite-Rod Antenna.

ferrodynamic instrument — An electrodynamic instrument in which the measuring forces are materially increased by the presence of ferromagnetic material.

ferroelectric—Pertaining to a phenomenon exhibited by certain materials in which the material is polarized in one direction or the other, or reversed in direction by the application of a positive or negative electric field of magnitude greater than a certain amount. The material retains the electric polarization unless it is disturbed. The polarization can be sensed by the fact that a change in the field induces an electromotive force which can cause a current.

ferroelectric converter—A device which generates high voltage when heat is applied to it. Its operation is based on the change in the dielectric constant or the permittivity of certain materials such as barium titanate when heated. This change reaches maximum at the Curie point.

ferroelectric crystal—A crystal which can be polarized in the opposite direction by applying an electric field weaker than the breakdown strength of the material.

ferroelectricity—A property of a crystal having a spontaneously reversible polarization.

ferroelectric materials—Those materials in which the electric polarization is produced by cooperation action between groups or domains of collectively oriented molecules.

ferroelectrics—Pyroelectric materials the direction of polarization of which can be reversed by application of an electric field.

ferromagnetic—Pertaining to a phenomenon exhibited by certain materials in which the material is polarized in one direction or the other, or reversed in direction by the application of a positive or negative magnetic field of magnitude greater than a certain amount. The material retains the magnetic polarization unless it is disturbed. The polarization can be sensed by the fact that a change in the field induces an electromotive force, which can cause a current.

ferromagnetic amplifier—A parametric amplifier based on the nonlinear behavior of ferromagnetic resonance at high r-f power levels. In one version, microwave pumping power is supplied to a garnet or other ferromagnetic crystal mounted in a cavity containing a strip line. A permanent magnet provides sufficient field strength to produce gyromagnetic resonance in the garnet at the pumping frequency. The input signal is applied to the crystal through the strip line, and the amplified output signal is extracted from the other end of the strip line. Sometimes incorrectly called a garnet maser, but the operating principle differs from that of the maser.

ferromagnetic material—A material having a specific permeability greater than unity, the amount depending on the magnetizing force. A ferromagnetic material usually has relatively high values of specific permeability and it exhibits hysteresis. The principal ferromagnetic materials are iron, nickel, cobalt, and certain of their alloys.

ferromagnetic oxide parts — Parts, consisting primarily of oxides which display ferromagnetic properties.

ferromagnetism — A high degree of magnetism in ferrites and similar compounds. The magnetic moments of neighboring ions tend not to align parallel with each other. The moments are of different magnitudes, and the resultant magnetization can be large.

ferromanganese—An alloy of iron and manganese.

ferrometer—An instrument for making permeability and hysteresis tests of iron and steel.

ferroresonance — Resonance associated with circuits in which at least one of the circuit elements is nonlinear and contains iron.

ferroresonant circuit—A resonant circuit in which one of its elements is a saturable reactor.

ferrospinel—A ceramic-like material containing iron and other elements combined with oxygen. A poor conductor of electricity, it is used in transformers, antenna loops, and television deflecting yokes.

ferrous — Composed of and/or containing iron. A ferrous metal exhibits magnetic characteristics, as opposed to a nonferrous metal such as aluminum which does not.

ferrule resistor—A resistor having ferrule terminals for mounting in standard fuse clips.

FET—Abbreviation for (unipolar) field effect transistor.

fetal electrocardiograph — An instrument for detecting and recording fetal ecg.

fetal heart monitor — An instrument that combines fetal ecg with an oscilloscope display and/or alarm.

fetal phonocardiograph — An instrument which provides continuous instantaneous recording of beat-to-beat changes in the fetal heart rate.

fetch—That portion of a computer cycle during which the location of the next instruction is determined. The instruction is taken from memory and modified if necessary, and it is then entered into the control register.

"f" factor — The slope of the straight line from which the nonlinearity of a displacement transducer is calculated in microvolts output per volt excitation per unit stimulus.

fiber—A tough insulating material, generally of paper and cellulose, compressed into rods, sheets, or tubes.

fiber needle—A playback point or phonograph needle made from fiber. Being softer than a metal or diamond needle, it is less scratchy; however, it has an extremely short life.

fiber-optic bundles—Assemblies of optical fibers.

fiber optics—Also called optical fibers or optical fiber bundles. An assemblage of transparent glass fibers all bundled together parallel to one another. The length of each fiber is much greater than its diameter. This bundle of fibers has the ability to transmit a picture from one of its surfaces to the other around curves and into otherwise inaccessible places with an extremely low loss of definition and light, by a process of total reflection.

fiber optics probe—A flexible probe made up of a bundle of fine glass fibers optically aligned to transmit an image.

fiber optics scrambler—Similar to a fiberscope except that the middle section of loose fiber is deliberately disoriented as much as possible, then potted and sawed. Each half is then capable of coding a picture, which can be decoded by the other half.

fiberscope—Optical glass fibers, when systematically arranged in a bundle, transmit a full color image that remains undisturbed when the bundle is bent. By mounting an objective lens on one end of the bundle, and an eyepiece at the other, the assembly becomes a flexible fiberscope that can be used to view objects that would be inaccessible for direct viewings.

fidelity—1. The accuracy with which a system or portion of a system reproduces at its output the essential characteristics of the signal impressed on its input. 2. A measure of the exactness with which sound is duplicated or reproduced.

field—1. One half of a television image. With present U. S. standards, pictures are transmitted in two fields of 262½ lines each, which are interlaced to form 30 complete frames, or images, per second. 2. A general term referring to the region under the influence of some physical agency such as electricity, magnetism, or a combination produced by an electrically charged object, electrons in motion, or a magnet. 3. A group of characters in a computer which is treated as a single unit of information. 4. In each of a number of punch cards, a column or columns regularly used for a standard item of information.

field application relay—A device which automatically controls the application of the field excitation to an a-c motor at some predetermined point in the slip cycle.

field circuit breaker—A device which functions to apply, or to remove, the field excitation of a machine.

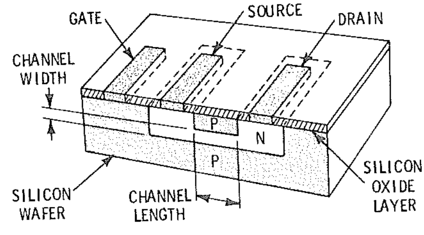
field coil—A coil of insulated wire wound around an iron core. Current flowing in the coil produces a magnetic field.

field density—*See* Magnetic Induction.

field-discharge protection — A control function or device to limit the induced voltage in the field when the field current attempts to change suddenly.

field distortion — Distortion between the north and south poles of a generator due to the counterelectromotive force in the armature winding.

field-effect tetrode—A semiconductor device consisting basically of a thin N region adjacent to a similarly thin P region. Two contacts are made to the N side and two to the P side so that currents can be passed through each thin region parallel to the single junction. The two currents remain separate because reverse bias is maintained on the junction. A current in either side affects the resistance of the other side and hence the current in the other side.



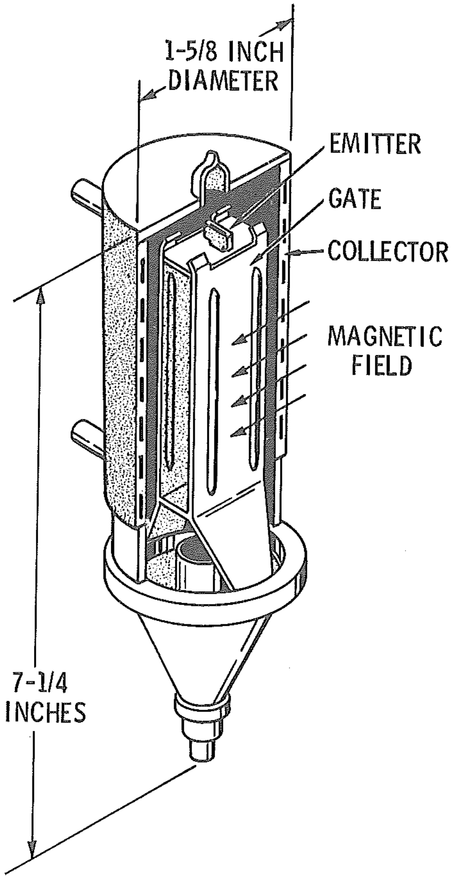
Field-effect transistor.

field-effect transistor—A transistor with a circuit application similar to that of a vacuum tube. The main conduction path is through a bar of N-type silicon, with control through depletion layers on each side of the N-type bar.

field-effect tube—A triode with its grid replaced by a nonintercepting control gate. A high positive voltage is applied to this gate in order to draw sufficient current from the cathode. The result is a strong concentration of the electric field at the gap between the gate and the cathode, producing an electron beam passing through the gate to the anode.

field emission—Also called cold emission. The liberation of electrons from a solid or liquid by application of a strong electric field at the surface.

field-enhanced photoelectric emission—Increased photoelectric emission resulting from



Field-effect tube.

the action of a strong electric field on the emitter.

field-enhanced secondary emission — Increased secondary emission resulting from the action of a strong electric field on the emitter.

field forcing—The effect of a control function or device which temporarily overexcites or underexcites the field of an electrical machine in order to increase the rate of change of flux.

field-free emission current — Also called zero-field emission. The electron current emitted by a cathode when the electric field at the surface of the cathode is zero.

field frequency—Also called field-repetition rate. In television, the frame frequency multiplied by the number of fields contained in one frame. In the United States the field frequency is 60 per second, or twice the frame frequency.

field intensity—*See* Field Strength.

field loss relay — *See* Motor Field Failure Relay.

field magnet—An electromagnet or permanent magnet which produces a strong magnetic field in a speaker, microphone, phonograph pickup, generator, motor, or other electrical device.

field-neutralizing coil—A coil encircling the faceplate of a color picture tube. The current through it produces a magnetic field which offsets any effects of the earth's and other stray magnetic fields on the electron beams.

field-neutralizing magnet—Also called rim magnet. A permanent magnet mounted near the edge of the faceplate of a color picture tube to prevent stray magnetic fields from affecting the path of the electron beams.

field of view—The solid angle from which objects can be acceptably viewed, photographed, or otherwise detected.

field period—The time required to transmit one television field. In the United States, it is 1/60th of a second.

field pickup—Also called a remote or nemo. A radio or television program originating outside the studio.

field relay — A device that functions on a given or abnormally low value or failure of machine field current, or on an excessive value of the reactive component of armature current in an a-c machine, indicating abnormally low field excitation.

field-repetition rate—*See* Field Frequency.

field resistor—A component in which the resistance element is a thin layer of conductive material on an insulated form. The conductive material does not contain either binding or insulating material.

field rheostat—A variable resistance connected to the field coils of a motor or generator and used for varying the field current.

field ring—The part which supports the field of a dc or series-wound motor housing. The motor end shields are attached to the ends of the field ring.

field selection—In a computer, the isolation of a particular data field with one computer word without isolating the word.

field sequential—Pertaining to the association of individual primary colors with successive fields in a color-television system (e.g., field-sequential pickup, display, system, transmission).

field-sequential color television—A color-television system in which the individual primary colors (red, blue, and green) are produced in successive fields.

field-simultaneous system — A color-television system in which a complete full-color field is presented simultaneously as a unit. The eyes then see a succession of full-color images rather than a succession of primary-color fields.

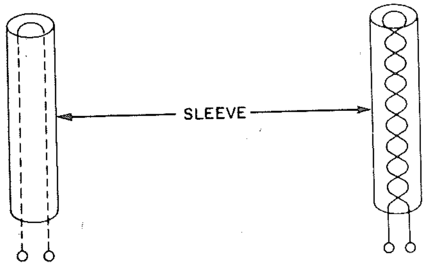
field strength—1. Also called field intensity. The value of the vector at a point in the region occupied by a vector field. In radio, it is the effective value of the electric-field intensity in microvolts or millivolts per meter produced at a point by radio waves from a particular station. Unless otherwise specified, the measurement is assumed to be in the direction of maximum field intensity. 2. The amount of magnetic flux produced at a particular point by an electromagnetic or permanent magnet.

field-strength meter—A calibrated measuring instrument for determining the strength of radiated energy (field strength) being received from a transmitter.

field telephone—A durable, portable telephone designed for use in the field.

field wire—A flexible insulated wire used in field-telephone and -telegraph systems.

figure of merit—1. The property or characteristic which makes a tube, coil, or other electronic device suitable for a particular application. It is a quality to look for in choosing a piece of equipment. 2. In a magnetic amplifier, the ratio of the power gain to the time constant. 3. For a thermoelectric material, the quotient of the square of the absolute Seebeck coefficient (α) divided by the product of the electrical resistivity (ρ) and the thermal conductivity.



Filaments (indirectly-heated).

filament—1. Also known as a filamentary cathode. The cathode of a thermionic tube, usually a wire or ribbon, which is heated by passing a current through it. 2. In tubes employing a separate cathode, the heating element.

filamentary transistor — A conductivity-modulation transistor which is much longer than it is wide.

filament battery—The source of energy for heating the filament of a vacuum tube.

filament circuit — The complete circuit through which filament current flows.

filament current—The current supplied to a filament to heat it.

filament emission—The liberation of electrons when the filament in a vacuum tube is heated.

filament power supply—The source of power for the filament or heater of a vacuum tube.

filament resistance — The resistance (in ohms) of the filament of a vacuum tube or incandescent lamp.

filament rheostat — A variable resistance placed in series with the filament of a vacuum tube to regulate the filament current.

filament sag—The bending of a filament when it heats up and expands.

filament saturation—Also called temperature saturation. The condition whereby a further increase in filament voltage will no longer increase the plate current at a given value of plate voltage.

filament transformer—A transformer used exclusively to supply filament voltage and current for the vacuum tubes.

filament voltage—The voltage value which must be applied to the filament of a vacuum tube to obtain the rated filament current.

filament winding—A secondary winding provided on a power transformer to furnish alternating filament voltage for one or more vacuum tubes.

file—1. A collection of related records—e.g., in inventory control, one line of an invoice containing data on the material, the quantity, and the price forms an item; a complete invoice forms a record; and the complete set of such records forms a file. 2. To insert an item into such a set.

file gap—A space or interval of time, the purpose of which is to indicate or signal the end of a file.

file maintenance—The processing of a computer file in order to bring it up to date.

filler—1. In mechanical recording, the inert material of a record compound (as distinguished from the binder). 2. Nonconducting component cabled with insulated conductors to impart roundness, flexibility, tensile strength, or a combination of all three, to the cable.

film badge — A type of dosimeter consisting of a badge containing a sensitized film which, when developed, gives an indication of the total dose of ionizing radiation to which the badge has been subjected.

film integrated circuit—An integrated circuit the elements of which are films formed *in situ* upon an insulating substrate. (*Also see* Integrated Circuit.) To further define the nature of a film integrated circuit, additional modifiers may be prefixed. Examples are: thin-film integrated circuit; thick-film integrated circuit.

film pickup—A film projector combined with a television camera for telecasting scenes from a motion-picture film.

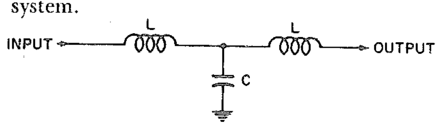
film reader—A computer input device which scans opaque and transparent patterns on photographic film and relays the corresponding information to the computer.

film recorder—A device that receives information from a computer and records it on photographic film.

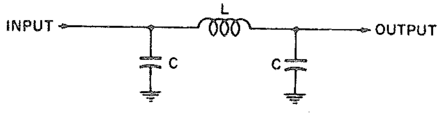
film reproducer—An instrument which reproduces a recording on film.

film resistor—A fixed resistor the resistance element of which is a thin layer of conductive material on an insulated form. Some sort of mechanical protection is placed over this layer.

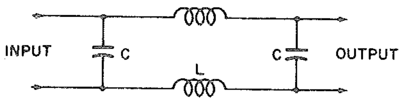
film scanning—The process of converting movie film into corresponding electrical signals that can be transmitted by a television system.



(A) T-section filter.



(B) Pi-section filter.



(C) Ladder-section filter.

Filters (wave filters).

filter—1. A selective network of resistors, inductors, or capacitors which offers comparatively little opposition to certain frequencies or to direct current, while blocking or attenuating other frequencies. 2. Also called a wave filter. A tuned circuit designed to pass a-c signals of a specified frequency. 3. A pattern of characters used to control the selection or elimination of portions of another pattern of characters. 4. A device or program that separates data, signals, or materials in accordance with specified criteria. 5. Also called extractor or mask. A machine word that specifies which parts of another machine word are to be operated on.

filter attenuation band—Also called a filter stop band. A frequency band in which the attenuation constant is not zero if dissipation is neglected. In other words, a frequency band of attenuation.

filter capacitor—A capacitor used in a filter circuit. The term is usually reserved for electrolytic capacitors in a power-supply filter circuit.

filter center—In an aircraft control and warning system, a location at which information from observation posts is filtered for further dissemination to air-direction centers.

filter choke — Normally, an iron-core coil which allows direct current to pass while opposing the passage of pulsating or alternating current.

filter-impedance compensator—An impedance compensator which is connected across the common terminals of electric-wave filters, when the latter are used in parallel, in order to compensate for the effects of the filters on each other.

filter passband — *See* Filter-Transmission Band.

filter slot—A choke, in the form of a slot, designed to suppress unwanted modes in a waveguide.

filter stop band — *See* Filter Attenuation Band.

filter-transmission band — Also called filter passband. A frequency band in which the attenuation constant is zero if dissipation is neglected. In other words, a frequency band of free transmission.

final actuation time—The time of termination of the chatter of a relay following contact actuation.

final amplifier—The stage which feeds the antenna in a transmitter.

final wrap — The outer layer of insulation around a coil, covering the saddle and splice insulation.

finder — In a telephone switching system, a name applied to the switch or relay group that selects the path which the call is to follow through the system.

fine-chrominance primary—Also called the I-signal. In the color television system presently standardized for broadcasting in the United States, the chrominance primary associated with the greater transmission bandwidth.

fine-tuning control—A receiver control which varies the frequency of the local oscillator over a small range to compensate for drift and permit fine adjustment to the carrier frequency of a station.

finished blank—A crystal product after completion of all processes. It may also include the electrodes adherent to the crystal blank.

finishing — The process of repeated hand lapping and electrical testing by which a finished crystal blank is brought up to specifications.

finishing rate—Expressed in amperes, the rate of charge to which the charging current of a battery is reduced near the end of the charge to prevent excessive gassing and temperature rise.

finish lead—The lead connected to the finish, or outer end, of a coil.

finite—Having fixed and definite limits.

fins—Radial sheets or discs of metal attached to metal parts of a power tube or other component for the purpose of dissipating heat.

fire-control equipment — Equipment that takes in target indications from optical or radar devices and, after calculating the motion of the target and firing vehicle, properties of air, etc., puts out directions of bearing, elevation, and timing for aiming and firing the guns.

fire-control radar—Radar employed for directing gunfire against the targets it observes.

fired tube (TR, ATR, and pre-TR tubes)—The condition of a tube while a radio-frequency glow discharge exists at the resonant gap, resonant window, or both.

firing—1. In any gas- or vapor-filled tube, the ionization of the gas and the start of current flow. 2. The excitation of a device during a brief pulse. 3. In a magnetic amplifier, the transition from the unsaturated to the saturated state of the saturable reactor during the conducting or gating alternation. 4. An adjective modifying phase or time, to designate when firing occurs.

firing angle—1. The electrical angle of the plate-supply voltage at which an ionization of a gaseous tube occurs. 2. In a magnetic amplifier, the point on a sine-wave control voltage at which the control ampere-turns are sufficient to saturate the cure. This is the point where the secondary winding (load) impedance drops to zero, and almost all of the supply voltage appears across the load.

firing point—The point at which the gas or vapor in a tube ionizes and current begins to flow.

firing potential—The controlled potential at which conduction through a gas-filled tube begins.

first audio stage—The first stage in an audio amplifier.

first detector—Now called the mixer. In a superheterodyne receiver, the stage where the local-oscillator signal is combined with the modulated incoming radio-frequency signal to produce the modulated intermediate-frequency signal.

first Fresnel zone—In optics and radio communications, the circular portion of a wave front intersecting the line between an emitter and a more distant point where the resultant disturbance is being observed. The center intersects the front with the direct ray, and the radius is such that the shortest path from the emitter through the periphery to the receiving point is one-half wave longer than the ray.

fishbone antenna—An antenna consisting of a series of coplanar elements arranged in collinear pairs and loosely coupled to a balanced transmission line.

fishpaper—A tough fiber used in sheet form for insulating transformer windings from the core, field coils from field poles, or conductors from the armature.

fission—Also called atomic fission or nuclear fission. The splitting of an atomic nucleus into two parts. Fission reactions occur only with heavy elements such as uranium and plutonium and are accompanied by large amounts of radioactivity and heat.

fissionable—Capable of undergoing fission.

fission products—The elements which result from atomic fission. They may consist of more than forty different radioactive elements such as arsenic, silver, cadmium, iodine, barium, tin, cerium, and others.

fitting—An accessory, such as a locknut or bushing, to a wiring system. Its function is primarily mechanical rather than electrical.

fix—A position determined without reference to any former position.

fixed bias—A constant value of bias voltage.

fixed capacitor—A capacitor designed with a definite capacitance that cannot be adjusted.

fixed crystal—A crystal detector with a nonadjustable contact position.

fixed-cycle operation—1. A type of computer performance whereby a fixed amount of time is allocated to an operation. 2. Synchronous or clock-type arrangement in a computer in which events occur as a function of measured time.

fixed echo—A stationary echo indication on a radar ppi display, indicating a fixed target.

fixed-frequency iff—A class of iff (identification friend or foe) equipment which responds immediately to every interrogation, thus permitting the response to be displayed on plan-position indicators.

fixed-frequency transmitter—A transmitter designed for operation on a single carrier frequency.

fixed-point system—A system of notation in which a number is represented by a single set of digits and the position of the radix point is not numerically expressed. (*Also see* Floating-Point System.)

fixed-program computer — *See* Wired-Program Computer.

fixed resistor—A resistor designed to introduce only a predetermined amount of resistance into an electrical circuit and not adjustable.

fixed screen—Application of a potential to a screen grid which is unaffected by other operating conditions within the tube.

fixed service—Any service communicating by radio between fixed points, except broadcasting and special services.

fixed station—1. A station in the fixed service. (A fixed station may, as a secondary service, transmit to mobile stations on its normal frequencies.) 2. A permanent station which communicates with other fixed stations.

fixed transmitter — A transmitter operated from a permanent location.

fixed-voltage winding—The motor winding which is excited by a fixed voltage.

fl—Abbreviation for footlambert.

flag—A large sheet of metal or fabric for shielding television camera lenses from light.

flame-failure control—A system which automatically stops the fuel supply to a furnace if the pilot burner accidentally goes out.

flame microphone—A microphone in which the action of sound waves on a flame changes the resistance between two electrodes in the flame.

flame resistance — The characteristic of a material that prevents it from flaming when the source of heat is removed.

flame-resistant—*See* Flame-Retardant.

flame-retardant—Retarding ignition and the spread of flames, either inherently or because of special treatment. Also called flame-resistant.

flammability — The ability of a material to support combustion.

flammable—Term applied to material which readily ignites and burns when exposed to flames or elevated temperatures. Also called combustible.

flange—Also called waveguide flange. A fitting used at the end of a waveguide to a microwave component or to another waveguide.

flange connector—A mechanical joint employing plane flanges bolted together in a waveguide.

flange coupling — A connection utilizing flanges not in mechanical contact between two parts of a waveguide, yet introducing no discontinuity in the flow of energy along the guide.

flanking effect—The effect on filter characteristics of connecting additional filters in parallel.

flap attenuator — A form of waveguide attenuator in which a variable amount of loss is introduced by insertion of a sheet of resistive material, usually through a nonradiating slot.

flare—An enlarged and distorted radar-screen target indication due to excessive brightness.

flare angle—The continuous change in cross section of a wave guide.

flare factor—A number expressing the degree of outward curvature of a speaker horn.

flash—Sometimes called hit. Momentary interference to a television picture, lasting approximately one field or less and of sufficient magnitude to totally distort the picture information. In general, this term is used only when the impairment is so short that the basic impairment cannot be recognized.

flashback voltage—The inverse peak voltage at which ionization takes place in a gas tube.

flasher — A device, generally a thermal or motor-driven switch, that rapidly and automatically lights and extinguishes electric lamps.

flasher relay—A self-interrupting relay.

flashing — The application of a high-frequency electromagnetic field to an electron tube through the envelope to flash its getter during evacuation.

flashing of a dynamo — The flashing or sparking which is likely to take place at the brushes of a commutator.

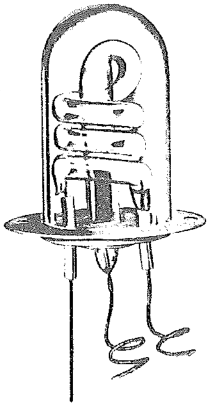
flash magnetization — Magnetization of a ferromagnetic object by an abrupt current impulse.

flashover — A disruptive discharge through air, around or over the surface of insulation, or between parts of different potential or polarity produced by the application of voltage, wherein the breakdown path becomes sufficiently ionized to maintain an electric arc.

flashover voltage—1. The highest value attained by any voltage impulse which caused a flashover. 2. The voltage at which insulation fails by discharge between electrodes across the insulation surface.

flash pulsing—Transmission of short bursts of radiation at irregular intervals by a mechanically controlled keyer.

flash test—A method of testing insulation by momentarily applying a voltage much higher than the working voltage.



Flash tube.

flash tube—Also called electronic flash tube and photoflash tube. A gas-discharge tube for producing high-intensity, short-duration flashes of light. It consists of a glass tube bent in a U, a helix, or a combination of the two and filled with a rare gas. The tube has an anode, a cold cathode, and a trigger electrode. It is flashed by applying a high-voltage pulse to the trigger electrode.

flash welding—Welding in which an arc is first struck between the pieces to be welded. After the ends are thus heated, the weld is completed by bringing them together under pressure and cutting off the current.

flat fading—That type of fading in which all components of the received radio signal fluctuate in the same proportion simultaneously.

flat, flexible cable—*See* Tape Cable.

flat frequency response—The response of a system in a constant-amplitude function which varies in frequency. The response is flat if it varies within specified limits of amplitude, usually specified in decibels from a reference quantity.

flat leakage power (TR and pre-TR tubes) —The peak radio-frequency power transmitted through the tube after establishment of a steady-state radio-frequency discharge.

flat line—A radio-frequency transmission line or part of a line having a low standing-wave ratio.

flat pack—A flat, rectangular integrated-circuit or hybrid-circuit package with coplanar leads.

flat response—Ability of a sound system to reproduce all tones, from the lowest to the highest, in the proper proportion.

flat top—The horizontal portion of an antenna.

flat-top antenna—An antenna having two or more lengths of wire parallel to each other and to the ground.

flat-top response—Response characteristic in which a definite band of frequencies is transmitted uniformly.

flat-type armature — Of a relay, an armature which rotates about an axis perpendicular to that of the core, with the pole face on a side surface of the core.

flat-type relay — A relay having a flat-type armature.

flaw—In a material, any discontinuity that would be harmful to proper functioning of the material.

flaw detection—The process of using sonic or ultrasonic waves to locate imperfections in a solid material. This is done by transmitting the waves through the material and listening for reflections or variations in transmission when they strike an imperfection in the material.

F layer—An ionized layer in the F region, existing in the night hemisphere and in the weakly illuminated portion of the day hemisphere.

F$_1$ layer — One of the regular ionospheric layers at an average height of about 225 kilometers, which occurs during the daylight hours.

F$_2$ layer—The most useful of the ionospheric layers for radio-wave propagation. It is the most highly ionized and highest of the layers, having an average night height of 225 kilometers and a midday height of about 400 kilometers.

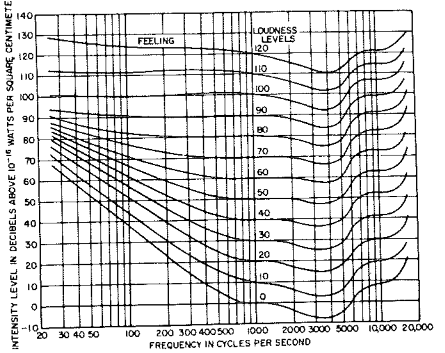
Fleming's rule—Also called the right-hand or left-hand rule. If the thumb and the first and second fingers are extended at right angles to one another, with the thumb representing the direction of the wire motion, the first finger representing the direction of magnetic lines of force (from the north pole to the south pole), and the second finger representing the direction of the current, then the right hand will give the correct relationships for a conductor in the armature of a generator, and the left hand will give the correct relationships for a conductor in the armature of a motor. This rule is applied to the so-called conventional current flow, which is the opposite of electron flow.

Fleming valve—An early name for a diode, or two-electrode thermionic vacuum tube used as a detector.

Fletcher-Munson curves—Also called equal-loudness contours. A group of sensitivity curves showing the characteristics of the human ear for different intensity levels between the threshold of hearing and the threshold of feeling. The reference frequency is 1,000 Hz.

Flewelling circuit—An early radio circuit in which one tube served as a detector, amplifier, and local oscillator.

flexible coupling—1. A device for connecting two shafts end to end so that they can be rotated even though not exactly aligned. 2. Mechanical connection between two lengths of waveguide normally lying in a straight line and designed to allow a limited angular movement between axes.

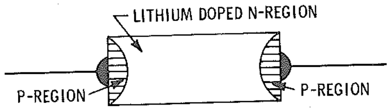


Fletcher-Munson curves.

flexible resistor—A wirewound resistor that looks like a flexible lead. It is made by winding *Nichrome* or any other type of resistance wire around asbestos or other heat-resistant cord. The wire is then covered with braided insulation, which is color coded to indicate the resistor value.

flexible shaft—A flexible core made up of layers of wire, which rotate inside a metal or rubber-covered flexible casing. The casing not only supports the core, but also acts as the bearing surface for the core.

flex life — A measure of the resistance of a conductor or other device to failure due to fatigue from repeated bending.



Flexode.

flexode—A flexible diode containing a junction that may be altered at will from a PN junction in one direction, to no junction at all, to a PN junction in the opposite direction. Thus the direction of easy current may be reversed without reversing the leads to the diode, and the resistance of the diode may be continuously varied from the back-resistance value to the forward-resistance value. It may be set to behave as a simple resistor, with the same value for both directions of current.

flicker—1. In television, the flickering produced in the picture when the field frequency is insufficient to completely synchronize the visual images. 2. In a regulated power supply, a phenomenon due primarily to sudden, minute changes of brief duration in the reference voltage or the input-stage junctions of the correction amplifier in the regulator. 3. Also called jitter or wobble. Noise in an amplifier, of higher frequency than drift, but lower than power-line or chopper-drive frequency noise.

flicker effect—Small variations in the plate current of a thermionic vacuum tube, believed to be due to random emission of positive ions by the cathode.

flicker photometer—A device for measuring the intensity of a light source. Illumination from the light source being measured and a standard light source are observed alternately in rapid succession. When the standard source is equal to the other, the flickering disappears.

flight control—Real-time calculations for the control of a vehicle in flight; includes stabilization, fuel monitoring, cruise control, etc.

flight path—A planned course for an airborne vehicle.

flight-path computer—A computer that includes all the functions of a course-line computer and also controls the altitude of an aircraft in accordance with a desired plan of flight.

flight-path deviation — The difference between the flight track of an aircraft and the actual flight path expressed in terms of either angular or linear measurement.

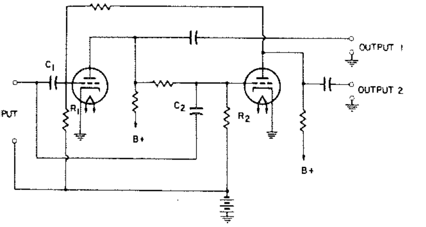
flight-path-deviation indicator—An instrument that provides a visual indication of deviation from a flight path.

flight track—The three-dimensional path in space actually traced by a vehicle.

Flinders bar—A bar of soft iron placed near a compass to correct errors due to variation of the vertical component of the earth's magnetism in different parts of the world.

flip-chip—An unencapsulated semiconductor device in which bead-type leads terminate on one face to permit flip (face-down) mounting of the device by contact of the leads to the required circuit interconnectors.

flip coil—A small coil used for measuring a magnetic field. When connected to a ballistic galvanometer or other instrument, it gives an indication whenever the magnetic field of the coil or its position in the field is suddenly reversed.



Flip-flop circuit.

flip-flop—Also called bistable multivibrator, Eccles-Jordan circuit, or trigger circuit. 1. A two-stage multivibrator circuit having two stable states. In one state, the first stage is conducting and the second is cut off. In the other state, the second stage is conducting and the first stage is cut off. A trigger signal changes the circuit from one state to the other, and the next trigger signal changes it back to the first state. For counting and scaling purposes, a flip-flop can be used to deliver one output pulse for each two input pulses. 2. A similar bistable device with an input which allows it to act as a single-stage binary counter.

flip-flop equipment—An electronic or electromechanical device which causes automatic alternation between two possible circuit paths. The same term is often applied to any mechanical operation which is analogous to the principles of the flip-flop.

flip-flop multivibrator—Also called start-stop multivibrator. A biased rectangular wave generator which operates for one cycle when a synchronizing trigger signal is applied.

flipover cartridge — A phonograph cartridge having separate needles for playing microgrove and standard records. It may be turned to bring the proper needle into playing position.

floated battery—A storage battery kept fully charged across the leads of a generator. The generator carries the normal load, and the battery assists during peaks.

floating — 1. Keeping a storage battery connected in parallel with an electric supply to serve as a standby in case of supply failure and to assist in handling peak loads. 2. The condition of a device or circuit that is not grounded and not tied to any established potential.

floating address—*See* Symbolic Address.

floating-carrier modulation—*See* Controlled-Carrier Modulation.

floating charge—Continuous charging of a storage battery with a low current to keep the battery fully charged while idle or on light duty.

floating grid—A vacuum-tube grid that is not connected to any circuit. It assumes a negative potential with respect to the cathode.

floating input—1. An isolated input circuit not connected to ground at any point (the maximum permissible voltage to ground is limited by electrical design parameters of the circuit involved). It is understood that in a floating input circuit, both conductors are equally free from any reference potential, a qualification which limits the types of signal sources which can be operated floating. 2. *See* Differential Input Measurement.

floating junction—A semiconductor junction through which no net current flows.

floating neutral—A circuit in which the voltage to ground is free to vary with circuit conditions.

floating-point calculation—In a computer, a calculation taking into account the varying location of the decimal point (if base 10) or binary point (if base 2). The sign and coefficient of each number are specified separately.

floating-point routine — Coded instructions in proper sequence to direct a computer to perform a calculation with floating-point operation.

floating-point system—A system of numbering in which an added set of digits is used to denote the location of the radix point. (*Also see* Fixed-Point System.)

floating potential—The d-c voltage between an open-circuited terminal of a circuit and a reference point when a d-c voltage is applied to the other circuit terminals as specified.

float switch—A switch actuated by a float on the surface of a liquid.

flock—Finely divided felt used on phonograph turntables, underneath microphone stands, or wherever a nonscratching surface is desired.

flow—1. The passage of electrons (a current) through a conductor or through the space between electrodes. 2. A general term to indicate a sequence of events.

flowchart—*See* Flow Diagram.

flow diagram—Also called flowchart. A chart showing all the logical steps of a computer program. A program is coded by writing down the successive instructions that will cause the computer to perform the logical operations necessary for solving the problem, as represented on a flowchart.

flowed wax—A mechanical recording disc prepared by melting and flowing wax onto a metal base.

flowmeter—A device for measuring the rate of flow of liquids or gases.

flow soldering—Also called wave soldering. A method of soldering printed-circuit boards by moving them over a flowing wave of molten solder in a solder bath.

fluctuating current—A direct current that changes in value, but not at a steady rate.

fluctuation noise—*See* Random Noise.

fluctuation voltage—Small voltage variations in a thermionic tube due to thermal agitation, shot effect, flicker effect, etc.

fluid damping—Damping obtained through displacement of a viscous fluid and the accompanying dissipation of heat.

fluorescence—Emission of light when a material is excited by electrons, ultraviolet radiation, or X rays.

fluorescent—Having the property of giving off light when activated by electronic bombardment or a source of radiant energy.

fluorescent lamp—An electric discharge lamp in which a gas ionizes and produces radiation that activates the fluorescent material inside the glass tubing. The phosphors in the fluorescent material transform the radiant energy from the electric discharge into wavelengths giving more light (higher luminosity).

fluorescent material—A material that fluoresces readily when exposed to electron beams, X rays, or other radiation.

fluorescent screen—The coating, on the face of a cathode-ray or television picture tube, which glows under electron bombardment.

fluorometer — An instrument for measuring fluorescence.

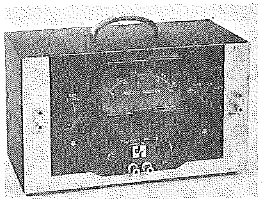
fluoroscope—An instrument with a fluorescent screen suitably mounted with respect to an X-ray tube, used for immediate indirect viewing of internal organs of the body, or internal structures in apparatus or masses of metals, by means of X rays. A fluorescent image (really a kind of X-ray shadow picture) is produced.

fluoroscopy—The use in diagnosis, testing, etc., of a fluorescent screen activated by X rays.

flush receptacle—A receptacle recessed into a wall, with only the plate extending beyond the surface.

flush-type instrument—An instrument designed to be mounted with its face projecting only slightly from the front of the panel.

flutter—1. Also called wow and drift. The frequency deviations produced by irregular motion of the turntable during recording, duplication, or reproduction. The term "flutter" usually refers to relatively high cyclic deviations (for example, 10 hertz), and the term "wow" to relatively low ones (for example, a variation of once per revolution). The term "drift" usually refers to a random rate close to zero hertz. 2. In communications, (a) distortion due to variations in loss resulting from simultaneous transmission of a signal at another frequency, or (b) a similar effect due to phase distortion.



Flutter bridge.

flutter bridge—An instrument for measuring the irregularities in a constant-speed device such as a film, disc, or tape recorder.

flutter echo—1. A rapid succession of reflected pulses resulting from a single initial pulse. 2. A multiple echo in which the reflections occur in rapid succession. If periodic and audible, it is referred to as a musical echo.

flutter rate—The number of times per second the flutter varies.

flux—1. A material used to promote the joining of metals in soldering. Rosin is widely used in soldering electronic parts. 2. Number of particles crossing a unit area per unit time. The common unit of flux is particles/cm²/sec. Integrated flux, after an exposure of time T, is equal to the total number of particles which have traversed a unit area during time T.

flux density—Also called induction density. The number of magnetic lines of force passing through a unit area.

fluxgate—A magnetic azimuth-sensitive element of the fluxgate-compass system activated by the earth's magnetic field.

fluxgate compass—A gyrostabilized, remote-indicating compass and azimuth-control system used with automatic pilots.

fluxgraph — A machine that automatically plots on paper the magnetic field strength at various points in the vicinity of a coil.

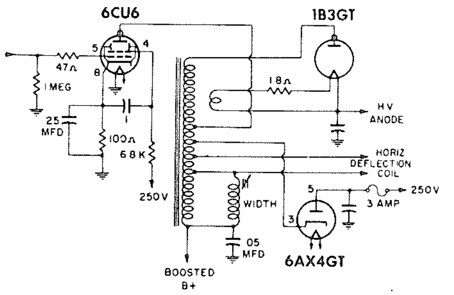
flux guide—In induction heating, a magnetic material used for guiding the electromagnetic flux to the desired location or for confining it to definite regions.

flux linkage—Magnetic lines of force which link a coil of wire. Whenever the flux linkage changes, an emf is generated in the coil.

fluxmeter—An instrument used with a test coil for measuring magnetic flux. It consists usually of a moving-coil galvanometer in which the torsional control is either negligible or compensated.

flyback—1. The shorter of the two time intervals comprising a sawtooth wave. 2. Also called retrace. As applied to a cathode-ray tube, the return of the spot to its starting point after having reached the end of its trace. This portion of the wave is usually not seen because of blanking circuits or the shortage of time.

flyback checker — An instrument used to check flyback or other transformers or inductors for open windings or shorted turns.



Flyback power supply.

flyback power supply—The power supply that generates the high d-c voltage required by the second anode of a picture tube. This voltage is produced during the flyback period, the current in the horizontal-deflecting coils reversing and inducing a sharp pulse in the primary of the transformer supplying the deflection circuit. This pulse is stepped up by an autotransformer and rectified. After suitable filtering, it becomes a very high d-c voltage.

flyback tester—An instrument that tests flyback transformers and sometimes also deflection yokes.

flyback time—The period during which the electron beam is returning from the end of a scanning line to begin the next line.

flyback transformer—Also called horizontal-output transformer. A transformer used in the horizontal-deflection circuit of a television receiver to provide the horizontal-scanning and accelerating-anode voltages for the cathode-ray tube. It also supplies the filament voltage for the high-voltage rectifier.

flycutter—An accessory used with a drill press to cut out large holes in metal or wood.

flying spot—A small, rapidly moving spot of light, usually generated by a cathode-ray tube, used to scan an image field for television transmission.

flying-spot scanner—1. Also called light-spot scanner. A television scanning device embodying a small beam which is moved over a scene or film and translates the highlights and shadows into electrical signals. 2. In optical character recognition, a device employing a moving sopt of light to scan a sample space, the intensity of the transmitted or reflected light being sensed by a photoelectric transducer.

flywheel effect—The maintaining of oscillations in a circuit in the intervals between pulses of excitation energy. The action is analogous to the rotation of a flywheel due to its stored mechanical energy.

flywheel synchronization—Automatic frequency control of a scanning circuit. The sweep oscillator responds to the average timing of the sync pulses, not to each pulse individually.

flywheel tuning—A tuning-dial mechanism which uses a heavy flywheel on the control shaft for added momentum, to obtain a smoother tuning action.

f-m—Abbreviation for frequency modulation.

fm/am—A system in which information subcarriers are frequency-modulated and are used to amplitude-modulate the carrier.

f-m broadcast band—The band of frequencies extending from 88 to 108 MHz, which include those assigned to noncommercial educational broadcasting.

f-m broadcast channel—A band of frequencies 200 kHz wide and designated by its center frequency. Channels for f-m broadcast stations begin at 88.1 MHz and continue in successive steps of 200 kHz to and including 107.9 MHz.

f-m broadcast station—A station employing frequency modulation in the f-m broadcast band and licensed primarily for the transmission of radio-telephone emissions intended to be received by the general public.

f-m discriminator—A device which converts frequency variations to proportional variations in the amplitude of an electrical signal. Discriminators may be of several basic types, such as pulse averaging, Foster-Seely, ratio detector, or phase-lock correlation detector.

f-m discriminator (subcarrier)—The same as an f-m discriminator except that it is used to convert subcarrier frequency variations into proportional voltage or current signals.

fm/pm—A system in which information subcarriers are frequency-modulated and used to phase-modulate the carrier.

f-m multiplex—*See* F-M Stereo.

f-m radar—*See* Frequency-Modulated Radar.

f-m recording (magnetic tape)—A method of recording in which the input signal modulates a voltage-controlled oscillator, the output of which is delivered to the recording head.

f-m stereo — Also called f-m multiplex. A means by which f-m radio stations are able to transmit stereophonic program material to specially designed receivers and which is at the same time compatible with monophonic equipment.

f-m stereophonic broadcast—The transmission of a stereophonic program by a single f-m broadcast stations utilizing the main channel and a subchannel to carry the signals required to produce the stereophonic effect.

focal length—Symbolized by *f*. The distance from the principal focus (focus of parallel rays of light) to the surface of a mirror or the optical center of a lens.

focometer—An instrument for measuring the focal length of a lens or an optical system.

focus—1. The convergence of light rays or an electron beam at a selected point. 2. The sharp definition of a scanning beam in television receivers or optical systems.

focus control—On a television receiver, a potentiometer control used for fine focusing of the electron beam. The control varies the first-anode voltage of an electrostatic tube or the focus-coil current of a magnetic tube.

focusing—The process of controlling the convergence and divergence of an electron or light beam.

focusing anode—One of the electrodes used to focus the electron beam in a cathode-ray tube. As its potential changes, so does the electric field, thereby altering the path of the electrons.

focusing coil—The coil around the neck of a cathode-ray tube. It provides a magnetic field, parallel to the electron beam, for controlling the cross-sectional area of the beam on the screen.

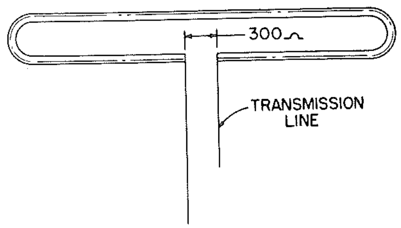
focusing electrode—An electrode to which a potential is applied to control the cross-sectional area of the electron beam.

focusing magnet—A permanent magnet assembly that produces a magnetic field for focusing the electron beam in a cathode-ray tube.

fold-back characteristic—*See* Current Limiting.

folded cavity—An arrangement used for producing a cumulative effect in a klystron repeater. This is done by making the incoming wave act in several places on the electron stream from the cathode.

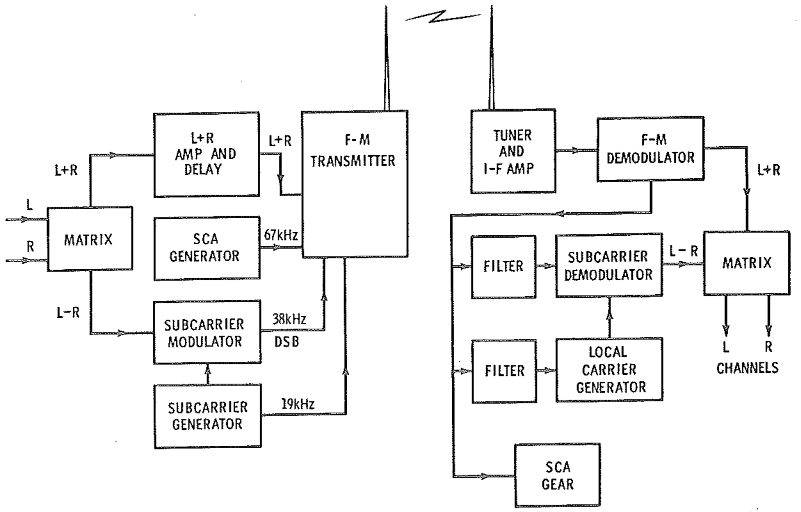
folded-dipole antenna—An antenna comprising two parallel, closely spaced dipole antennas. Both are connected together at their ends, and one is fed at its center.



Folded-dipole antenna.

folded heater—A strand of bent, coated wire inserted into a cathode sleeve.

folded horn—An acoustic horn which is



F-m stereophonic broadcast system.

curled to permit more efficient use of the space it occupies.

foldover—A distorted television picture, which appears to overlap horizontally or vertically. It is due to nonlinear horizontal- or vertical-sweep circuits.

follow current—That line current which tends to follow a lightning discharge through an arrester to ground.

follower—A circuit in which the output of a high-gain amplifier is fed directly back to its negative input. The input signal is reproduced without polarity reversal.

follower drive—Also called slave drive. A drive in which the reference input and operation are direct functions of a master drive.

follower with gain—A follower in which only a part of the output voltage is fed back in series opposition to the input signal. Hence, closed-loop gain greater than unity is obtained over the rated range of operation.

following blacks—Also called edge effect, trailing reversal, or trailing blacks. A picture condition in which the edge following a white object is overshaded toward black (i.e., the object appears to have a trailing black border).

following whites—Also called edge effect, trailing reversal, or trailing whites. A picture condition in which the edge following a black or dark gray object is shaded toward white (i.e., the object appears to have a trailing white border).

footcandle—Abbreviated fc. A unit of brilliance of a light. It is the luminance on a surface of one square foot on which a flux of one lumen is uniformly distributed, or the luminance at a surface one foot from a uniform source of one candlepower.

footlambert—A unit of luminance equal to $1/\pi$ candle per square foot, or to the uniform luminance of a perfect diffusing surface emitting or reflecting light at the rate of one lumen per square foot.

foot-pound—A unit of measurement equivalent to the work of raising one pound vertically a distance of one foot.

forbidden band—The energy band lying between the conduction and valence bands. The energy difference across it determines whether a solid acts as a conductor, semiconductor, or insulator.

forbidden energy gap—The energy range of a semiconductor between the bottom of the conduction band and the top of the valence band.

force—1. Any physical action capable of moving a body or modifying its motion. 2. In computer programming, manual intervention which directs the computer to execute a jump instruction.

force-balance transducer—A transducer in which the output from the sensing member is amplified and fed back to an element which causes a force-summing member to return it to its rest position. The magnitude of the signal fed back determines the output of the device, like the error signal in a servo signal.

forced coding—*See* Minimum-Access Programming.

force differential—The difference between the operating force and the release force of a momentary contact switch.

forced oscillation—In a linear constant-parameter system, the response to an applied driving force, excluding the transient which results from energy at the time the driving force is applied.

force factor (of an electromechanical or electroacoustic transducer)—1. The complex quotient of the force required to block the mechanical or acoustic system, divided by the corresponding current in the electrical system. 2. The complex quotient of the resultant open-circuit voltage in the electric system, divided by the velocity in the mechanical or acoustic system.

force-summing device—In a transducer the element directly displaced by the applied stimulus.

fore pump—An auxiliary vacuum pump used as the first stage in evacuating vacuum systems.

fork oscillator—An oscillator in which a tuning fork is the frequency-determining element.

fork tines—The projecting ends of a tuning fork. When vibrated, they produce a constant frequency.

formant—1. The particular frequency region in which the energy of a vowel sound is concentrated most strongly. 2. In an organ, an electrical circuit, the purpose of which is to alter the tone quality of sound amplified by it. A formant filter is applied to the entire output from a manual, rather than to individual tones.

formant filter—A waveshaping network used in an organ to modify the signal from the tone generator so it will assume the waveshape of the desired tone.

form factor—1. Ratio of the effective value of a current to its average value. 2. Shape (diameter/length) of a coil. 3. Ratio of the effective value of a symmetrical alternating quantity to its half-period average value.

Formica—Trade name for a phenolic compound having good insulating qualities.

forming—The application of voltage to an electrolytic capacitor, electrolytic rectifier, or semiconductor device to produce a desired permanent change in electrical characteristics as a part of the manufacturing process.

form-wound coil—An armature coil that is formed or shaped over a fixture before being placed on the armature of a motor or generator. Any coil wound on a fixture or dummy form.

FORTRAN—A computer programming system which enables the programmer to state,

in relatively simple language, the steps of a procedure to be carried out by the computer and to automatically obtain an efficient machine language program.

fortuitous telegraph distortion—Distortion other than bias or characteristic. It occurs when a signal pulse departs from the average combined effects of bias and characteristic distortion for one occurrence. Since fortuitous distortion varies from one signal to another it must be measured by a process of elimination over a long period. It is expressed in a percentage of unit pulse.

forty-five/forty-five—Also called the Westrex system. A system of disc recording in which signals originating from two microphones are impressed on each side of a groove. The two sides are cut 45° from the surface of the record.

forty-five record—A 7-inch record with a 1½-inch center hole. It is recorded at 45 rpm and played at the same speed.

forty-four-type repeater—Type of telephone repeater used in a four-wire system. It employs two amplifiers and no hybrid arrangements.

forward-acting regulator—A transmission regulator which makes an adjustment without affecting the quantity that caused the adjustment.

forward-backward counter—A counter having both an add and subtract input and thus capable of counting in either an increasing or a decreasing direction.

forward bias—An external voltage applied in the conducting direction of a PN junction. The positive terminal is connected to the P-type region, and the negative terminal to the N-type region.

forward coupler—A directional coupler used for sampling incident power.

forward current—The current which flows across a semiconductor junction when a forward-bias voltage is applied.

forward direction—The direction of easy current flow through a semiconductor device when a given voltage within the ratings of the device is applied. In a conventional rectifier or diode, the forward direction is from anode to cathode when the anode is at a positive voltage with respect to the cathode.

forward path—In a feedback control loop, the transmission path from the loop-actuating to the loop-output signal.

forward propagation ionospheric scatter—A radiocommunication technique using the scattering phenomenon exhibited by electromagnetic waves in the 30- to 100-megahertz region when passing through the ionosphere at an elevation of about 85 kilometers.

forward-propagation tropospheric scatter—A method of communication by means of ultrahigh frequency f-m radio. It provides reliable multichannel telephone, teletype, and data transmission without line-of-sight restrictions or the necessity of using wire or cables.

forward recovery time—In a semiconductor diode, the time required for the current or voltage to arrive at a specified condition after instantaneous switching from zero or a specified reverse voltage to a specified forward voltage.

forward resistance—The resistance measured at a specified forward voltage drop or forward current in a rectifier.

forward scatter—1. Propagation of electromagnetic waves at frequencies above the maximum usable high frequency through use of the scattering of a small portion of the transmitted energy when the signal passes from a nonionized medium into a layer of the ionosphere. 2. A term referring collectively to very-high-frequency forward propagation by ionospheric scatter and ultrahigh-frequency forward propagation by tropospheric scatter communication techniques.

forward scattering—The reflected radiation of energy from a target away from the illuminating radar.

forward short-circuit-current-amplification factor—In a transistor, the ratio of incremental values of output to input current when the output circuit is a-c short-circuited.

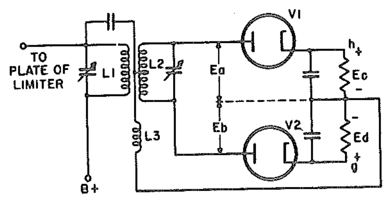
forward-transfer function—In a feedback control loop, the transfer function of the forward path.

forward voltage—Voltage of the polarity that produces the larger current.

forward voltage drop—The resultant voltage drop when current flows through a rectifier in the forward direction.

forward wave—In a traveling-wave tube, a wave with a group velocity in the same direction the electron stream moves.

Foster-Seeley discriminator—A type of frequency discriminator that converts a frequency-modulated signal into an audio signal. It requires a limiter to prevent random amplitude variations of the f-m signal from appearing in its output.



Foster-Seeley discriminator.

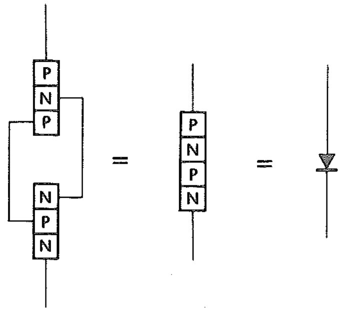
Foster's reactance theorem—The driving-point impedance of a finite two-terminal network composed of pure reactances is a reactance which is an odd rational function of frequency and which is completely determined, except for a constant factor, by assigning the resonant and antiresonant frequencies. In other words, the driving-point impedance consists of segments going from minus infinity to plus infinity (except that at zero, or infinite, frequency, a segment may start or stop at zero impedance). The frequencies at which the impedance is infinite are termed poles, and those at which it is zero are termed zeros.

Foucault currents—*See* Eddy Currents.

four-address code—An artificial language for describing or expressing the instructions carried out by a digital computer. In automatically sequenced computers, the instruction code is used for describing or expressing sequences of instructions. Each instruction word then contains a part specifying the operation to be performed, plus one or more addresses which identify a particular location in storage.

four-horn feed—A cluster of four rectangular horn antennas used as the radiating and receiving elements of parabolic or lens-type radar antennas. The four segments of the horn assembly define the four quadrants of information for direction to target sensing. Used on monopulse-type radar systems such as the AN/FPS-16.

Fourier series—A mathematical analysis that permits any complex waveform to be resolved into a fundamental, plus a finite number of terms involving its harmonics.



Four-layer diode.

four-layer diode—A semiconductor diode that has three junctions with connections made only to the two outer layers that form the junctions. A Shockley diode is an example.

four-layer transistor—A junction transistor that has four conductivity regions, but only three terminals. A thyristor is an example.

four-level system—A laser involving four electronic energy levels. The ground state (level 1) is pumped to level 4, from which the excited electrons make a downward transition to the upper laser level 3 (or metastable level 3). Then, stimulated transition to the lower laser level 2 occurs, followed by rapid decay to the ground state. The four-level system has the advantage that the pump level and ground state are isolated from the laser action.

four-pole network—*See* Two-Terminal-Pair Network.

four-track recording—Also called quarter-track. On quarter-inch-wide tape, the arrangement by which four different channels of sound may be recorded on adjacent tracks. These may be recorded as four separate and distinct tracks (monophonic), or two related (stereo) pairs of tracks. By convention, tracks 1 and 3 are recorded in the forward direction of a given reel, and tracks 2 and 4 are recorded in the reverse direction.

four-track tape—A tape with four recording strips which permits it to be played in both directions for stereo recordings, like a two-track monophonic tape. Thus, twice as much material can be recorded than on a two-track stereo tape.

four-wire circuit—A two-way circuit with two paths. Each path transmits the electric waves in one direction only. The transmission paths may or may not employ four wires.

four-wire repeater—A telephone repeater used in a four-wire circuit. It has two amplifiers; one amplifies the telephone currents in one side of the four-wire circuit, and the other in the other side.

four-wire terminating set—A hybrid arrangement involving termination of four-wire circuits on a two-wire basis for interconnection with two-wire circuits.

fox message—A standard message which is used for testing teletypewriter circuits and machines because it includes all the alphanumerics on a teletypewriter, as well as most of the function characteristics such as space, figures shift, letters shift, etc. It is: THE QUICK BROWN FOX JUMPED OVER A LAZY DOG'S BACK 1234567890——SENDING. The sending station's identification is inserted in the three space blanks which precede the word "sending."

fractional arithmetic units—Arithmetic units in a computer that is operated with the decimal point at the extreme left so that all numbers have a value less than 1.

fractional-horsepower motor—Any motor having a continuous rating of less than one horsepower.

Frahm frequency meter—A meter that measures the frequency of an alternating current. It consists of a row of steel reeds, each with a different natural frequency. All are excited by an electromagnet fed with the current to be measured. The reed that vibrates is the one with a frequency corresponding most nearly to that of the current.

frame—1. In television, the total area occupied by the picture. In the United States, each frame contains 525 horizontal scanning lines, and 30 complete frames are shown per second. 2. One cycle of a recurring number of pulses. 3. In pam and pdm, one complete commutator revolution or sweep. In pcm, a recurring group of words which includes a single synchronizing signal. 4. The array of binary digits across the width of magnetic or paper tape.

frame frequency—The number of times per second the picture area is completely scanned (30 per second in the United States television system).

frame grid—The grid of a vacuum tube consisting of a rigid welded frame on which tungsten wire is wound under tension, resulting in a firm precision structure that can be positioned accurately. It also allows the use of much finer grid wire, which reduces electron interception and power dissipation in the grid.

frame-grounding circuit—A conductor which is electrically bonded to the machine frame and/or to any conduction parts which are normally exposed to operating personnel. This circuit may further be connected to external grounds as may be required by applicable Underwriters code.

frame of reference—A set of points, lines, or planes used for defining space coordinates.

frame pulse synchronization—Synchronization of the local-channel rate oscillator by comparison and phase lock with the separate frame synchronizing pulses.

framer—A device for adjusting facsimile equipment so that the recorded elemental area bears the same relationship to the record sheet as the corresponding transmitted elemental area bears to the subject copy as the line progresses.

frame rate—*See* Frame Frequency.

frame roll—A momentary roll, or "flip-flop," of a television picture.

frame synchronization signal—In pam, a coded pulse or interval to indicate the start of the commutation frame period. In pcm, any signal used to identify a frame of data.

frame-synchronizing pulse—A recurrent signal that establishes each frame.

frame-synchronizing pulse separator—A circuit for separating frame-synchronizing pulses or intervals from commutated signals.

framing—1. Adjusting the picture to a desired position in the direction of line progression. 2. The process of selecting the bit groupings representing one or more characters from a continuous stream of bits.

framing bits—Also called sync bits. Noninformation-carrying bits used to make possible the separation of characters in a bit stream.

framing control—More often called centering control. A knob (or knobs) for centering and adjusting the height and width of a television picture.

framing magnet—More often called centering magnet. A magnet which centers the televised picture on the face of the tube.

Franklin antenna—An antenna which is several half-wavelengths long and has nonradiating phasing coils between half-wave sections.

Franklin oscillator—A two-terminal feedback oscillator using two tubes or transistors and having sufficient loop gain to permit extremely loose coupling to the resonant circuit.

Fraunhofer region—The region in which the energy from an antenna proceeds essentially as though coming from a source located in the vicinity of the antenna.

free electrons—Electrons which are not bound to a particular atom, but circulate among the atoms of a substance.

free energy—The available energy in a thermodynamic system.

free field—1. Theoretically, a field (wave or potential) which is free from boundaries in a homogeneous, isotropic medium. In practice, a field in which the effects of the boundaries are negligible over the region of interest. 2. A property of information-processing recording media which permits recording of information without regard to a preassigned or fixed field; e.g., information-retrieval-devices information may be dispersed in the record in any sequence or location.

free-field emission—Electron emission that occurs when the electric field at the surface of an emitter is zero.

free grid—A grid electrode that is left unconnected in a vacuum tube. Its potential exerts a control over the plate current.

free impedance—Also called normal impedance. The input impedance of a transducer when the load impedance is zero.

free magnetic pole—A magnetic pole so far from an opposite pole that it is free from the effect of the other pole.

free motional impedance—The complex remainder after the blocked impedance of a transducer has been subtracted from the free impedance.

free net—A net in which any station may communicate with any other station in the same net without first obtaining permission from the control station.

free oscillations—Commonly referred to as shock-excited oscillations. Oscillations that continue in a circuit or system after the applied force has been removed. The frequency of the oscillations is determined by the parameters of the system or circuit.

free-point tube tester—A tester instrument that permits transferring a tube from a circuit to a test panel at which either voltage or current measurement for any electrode of the tube is readily made by plugging a meter into appropriate jacks. Connections to the receiver are made by means of a cord and plug inserted into the socket from which the tube was removed.

free position—The initial position of the actuator of a momentary-contact switch when there is no external force (other than gravity) applied on the actuator, and the switch is in the specified position.

free progressive wave—Also called free wave. A wave free from boundary effects in a medium. In other words, there are no reflections from nearby surfaces. A free wave can only be approximated in practice.

free radicals—Atoms, ionized fragments of atoms, or molecules which combine and release enormous amounts of energy.

free reel—The reel which supplies the magnetic tape on a recorder.

free-rotor gyro — A gyro the rotor of which is supported by a gas-lubricated spherical bearing.

free-running frequency—The frequency at which a normally synchronized oscillator operates in the absence of a synchronizing signal.

free-running local synchronizer oscillator —A free-running oscillator circuit in the decommutator normally triggered by separated channel synchronizing pulses. It supplies substitute pulses for missing channel pulses.

free-running multivibrator — *See* Astable Multivibrator.

free-running sweep — A sweep operating without synchronizing pulses.

free sound field—A field in a medium free from discontinuities or boundaries. In practice it is a field in which the boundaries cause negligible effects over the region of interest.

free space—Empty space, or space with no free electrons or ions. It has approximately the electrical constants of air.

free-space field intensity—The radio-field intensity that would exist at a point in a uniform medium in the absence of waves reflected from the earth or other objects.

free-space loss—The theoretical radiation loss which would occur in radio transmission if all variable factors were disregarded.

free-space propagation—Electromagnetic radiation over a straight-line path in a vacuum or ideal atmosphere, sufficiently removed from all objects that affect the wave in any way.

free-space radar equation—The equation for determining the characteristic of a radar signal propagated between the radar set and a reflected target in free space.

free-space radiation pattern—The radiation pattern of an antenna in free space, where there is nothing to reflect, refract, or absorb the radiated waves.

free-space transmission — Electromagnetic radiation over a straight line in a vacuum or ideal atmosphere sufficiently removed from all objects that affect the wave.

free speed—The angular speed of an energized motor under no-load conditions. (*Also see* Angular Velocity.)

free wave—*See* Free Progressive Wave.

freewheeling circuit—A motor arrangement in which the field is shunted by a half-wave rectifier which discharges the energy stored in the field during the negative half cycles.

freeze-out—A short-time denial of a telephone circuit to a subscriber by a speech-interpolation system.

F-region — The region of the ionosphere above 100 miles.

freq—Abbreviation for frequency.

frequency—Symbolized by f. 1. The number of recurrences of a periodic phenomenon in a unit of time. Electrical frequency is specified as so many hertz. Radio frequencies are normally expressed in kilohertz at and below 30,000 kilohertz and in megahertz above this frequency. 2. Number of complete hertz of a wave motion (e.g., of an alternating current or sound wave).

frequency agility—The rapid and continual shifting of a radar frequency to avoid jamming by the enemy, reduce mutual interference with friendly sources, enhance echoes from targets, or provide necessary patterns of ecm (electronic countermeasures) or eccm (electronic counter-countermeasures) radiation.

frequency allocation — The assignment of available frequencies in the radio spectrum to specific stations, for specific purposes. This is done to yield maximum utilization of frequencies with minimum interference between stations. Allocations in the United States are made by the Federal Communications Commission.

frequency authorization—The document of power which legalizes the assignment of a frequency or a frequency band.

frequency band—A continuous and specific range of frequencies.

frequency band of emission—The frequency band required for a specific type of transmission and speed of signaling.

frequency bias—A constant frequency purposely added to the frequency of a signal.

frequency-change signaling — A telegraph signaling method in which one or more particular frequencies correspond to each desired signaling condition of a telegraph code. The transition from one set of frequencies to the other may be either a continuous or a discontinuous change in frequency or in phase.

frequency changer — *See* Frequency Converter.

frequency-changing circuit—A circuit comprising an oscillator and a mixer and delivering an output at one or more frequencies other than the input frequency.

frequency channel—A continuous portion of the appropriate frequency spectrum for a specified class of emission.

frequency compensation—A method of extending the higher or lower (or both) frequency ranges within which an amplifier has nearly uniform gain.

frequency constant—The number relating the natural vibration frequency of a piezoid (finished crystal blank) to its linear dimension.

frequency conversion—1. The process of converting a signal to some other frequency by combining it with another frequency. 2. Of a heterodyne receiving system, converting the carrier frequency of a received signal from its original value to the intermediate frequency value in a superheterodyne receiver.

frequency converter—Also called frequency changer. A circuit, device, or machine that changes an alternating current from one frequency to another, with or without a change in voltage or number of phases. In a superheterodyne receiver, the oscillator and mixer first-detector stages together serve as a frequency converter.

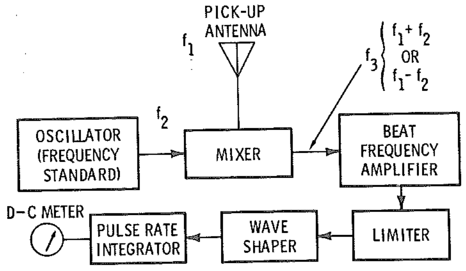
frequency correction — Compensation, by means of an attenuation equalizer, for unequal transmission of various frequencies in a line.

frequency cutoff—The frequency at which the current gain of a transistor drops 3 db below the low-frequency gain.

frequency demodulation—Removal of the intelligence from a modulated carrier.

frequency departure—The amount a carrier or center frequency deviates from its assigned value.

frequency deviation—In frequency modulation, the peak difference between the instantaneous frequency of the modulated wave and its carrier frequency.



Frequency-deviation meter.

frequency-deviation meter—An instrument that indicates the number of hertz a transmitter has drifted from its assigned carrier frequency.

frequency discrimination — A term applied to the operation of selecting a desired frequency or frequencies from a spectrum of frequencies.

frequency discriminator—A circuit that converts a frequency-modulated signal into an audio signal.

frequency distortion—1. The distortion that results when all frequencies in a complex wave are not amplified or attenuated equally. 2. The impairment of fidelity introduced by a transducer as a result of the unequal transfer of frequencies—e.g., unequal amplification of frequencies with the passband of an amplifier.

frequency distribution—The number of occurrences of particular values plotted against those values.

frequency diversity—*See* Frequency-Diversity Reception.

frequency-diversity reception—Also called frequency diversity. The form of diversity reception which utilizes transmission at different frequencies.

frequency divider—A device delivering an output voltage which is an integral submultiple or proper fraction of the input frequency.

frequency-division multiplex — Abbreviated fdm. A device or process for transmitting two or more signals over a common path by sending each one over a different frequency band.

frequency doubler—An electronic stage having a resonant plate circuit tuned to the second harmonic of the input frequency. The output signal will then have twice the frequency of the input signal.

frequency-doubling transponder — A transponder that doubles the frequency of the interrogating signal before retransmission.

frequency drift—Any undesired change in the frequency of an oscillator, transmitter, or receiver.

frequency-exchange signaling — The method in which the change from one signaling condition to another is accompanied by a decay in amplitude of one or more frequencies and by a build-up in amplitude of one or more other frequencies.

frequency frogging — The interchanging of the frequency allocations of carrier channels to prevent singing, reduce cross talk, and correct for line slope. It is accomplished by having the modulators in a repeater translate a low-frequency group to a high-frequency group and vice versa.

frequency indicator—A device which shows when two alternating currents have the same phase or frequency.

frequency interlace—In television, the relationship of intermeshing between the frequency spectrum of an essentially periodic interfering signal and the spectrum of harmonics of the scanning frequencies. Such relationship minimizes the visibility of the interfering pattern by altering its appearance on successive scans.

frequency keying—A method of keying in which the carrier frequency is shifted between two predetermined frequencies.

frequency-measuring equipment — Equipment for indicating or measuring the frequency or pulse-repetition rate of an electrical signal.

frequency meter—An instrument for measuring the frequency of an alternating current.

frequency-modulated broadcast band—The band from 88.1 to 107.9 megahertz. It is divided into 100 channels, each 200 kilohertz in width, and set aside for frequency-modulated broadcasting.

frequency-modulated, carrier-current telephony—A form of telephony in which a frequency-modulated carrier signal is transmitted over power lines or other wires.

frequency-modulated cyclotron—A cyclotron in which the frequency of the accelerating electric field is modulated in order to hold the positively charged particles in synchronism with the accelerating field despite their much greater mass at very high speeds.

frequency-modulated output—A transducer output which is obtained in the form of a deviation from a center frequency, where the deviation is proportional to the applied stimulus.

frequency-modulated radar—Also called f-m radar. A form of radar in which the radiated wave is frequency-modulated. The range is measured by beating the returning wave with the one being radiated.

frequency-modulated transmitter—One in which the frequency of the wave is modulated.

frequency-modulated wave—A carrier wave whose frequency is varied by an amount proportionate to the amplitude of the modulating signal.

frequency modulation — Modulation of a sine-wave carrier so that its instantaneous frequency differs from the carrier frequency by an amount proportionate to the instantaneous amplitude of the modulating wave. Combinations of phase and frequency modulation also are commonly referred to as frequency modulation. (*Also see* Frequency-Modulated Wave.)

frequency-modulation deviation—The peak difference between the instantaneous frequency of a modulated wave and the carrier or reference frequency.

frequency modulation-frequency modulation—A system in which the frequency-modulated subcarriers are used to frequency modulate a second carrier.

frequency modulation-phase modulation—A system in which the frequency-modulated subcarriers are used to phase-modulate a second carrier.

frequency monitor—An instrument for indicating the amount a frequency deviates from its assigned value.

frequency multiplex—A technique for the transmission of two or more signals over a common path. Each signal is characterized by a distinctive reference frequency or band of frequencies.

frequency multiplier—A device for delivering an output wave whose frequency is a multiple of the input frequency (e.g., frequency doublers and triplers).

frequency offset—The amount by which a frequency lies above or below a reference frequency. For example, if a frequency measures 1.000 001 MHz when compared against a reference frequency of 1.000 000 MHz, then its fractional frequency offset is 1 Hz/1 MHz, or 1 part in 10^6.

frequency offset transponder—A transponder which changes the interrogating signal frequency by a fixed amount before retransmission.

frequency output (transducer)—An output in the form of frequency which is a function of the applied measurand (e.g., angular speed and flow rate).

frequency overlap—1. In a color tv system, that part of the frequency spectrum occupied by both the monochrome and chrominance signals. 2. That part of the frequency band which is shared as a result of interleaving.

frequency pulling—A change in oscillator frequency due to a change in the load impedance.

frequency pushing — A change in the frequency of an oscillator due to a change in anode current or voltage.

frequency range—1. In a transmission system, those frequencies at which the system is able to transmit power without attenuating it more than an arbitrary amount. 2. In a receiver, the frequency band over which the receiver is designed to operate, covering those frequencies the receiver will readily accept and amplify. 3. A designated portion of the frequency spectrum.

frequency record—A recording of various known frequencies at known amplitudes, usually for testing purposes.

frequency regulator—A regulator that maintains the frequency of the frequency-generating equipment at a predetermined value or varies it according to a predetermined plan.

frequency relay—A relay which functions at a predetermined value of frequency. It may be an overfrequency or underfrequency relay, or a combination of both.

frequency response—1. A measure of how effectively a circuit or device transmits the different frequencies applied to it. 2. The portion of the frequency spectrum which can be sensed by a device within specified limits of amplitude error.

frequency-response characteristic — The amount by which the gain or loss of a device varies with the frequency.

frequency-response curve—A graphical representation of the way a circuit responds to different frequencies within its operating range.

frequency-response equalization — Also called equalization or corrective equalization. The effect of all frequency-discriminative means employed in a transmission system to obtain the desired overall frequency response.

frequency run—A series of tests for determining the frequency-response characteristics of a transmission line, circuit, or device.

frequency selectivity—The degree to which a transducer is capable of differentiating between the desired signal and between signals or interference at other frequencies.

frequency-sensitive relay—A relay that operates only when energized with voltage, current, or power within specific frequency limits.

frequency separator — The circuit which separates the horizontal-scanning from the vertical-scanning synchronizing pulses in a television receiver.

frequency shift—A system of telegraph operation in which the space signal is 70 hertz lower than the mark signal.

frequency-shift converter—A device which limits the amplitude of the received frequency-shift signal and then changes it to an amplitude-modulated signal.

frequency-shift indicator—In automatic code transmission, a device which designates mark and space by shifting the carrier back and forth between two frequencies instead of keying it on and off.

frequency-shift keying—Abbreviated fsk. A form of frequency modulation in which the modulating wave shifts the output frequency between predetermined values and the output wave has no phase discontinuity.

frequency-shift telegraphy—Telegraphy by frequency modulation in which the telegraph signal shifts the frequency of the carrier between predetermined values. There is phase continuity during the shift from one frequency to the other.

frequency-shift transmission—A method of transmitting the mark and space elements of a telegraph code by shifting the carrier frequency slightly, usually about 800 Hz.

frequency splitting—One condition of magnetron operation in which rapid alternation occurs from one mode of operation to another. This results in a similar rapid change in oscillatory frequency and consequent loss of power at the desired frequency.

frequency stability—The ability of electronic equipment to maintain the desired operating frequency.

frequency stabilization—The controlling of the center or carrier frequency so that it does not differ more than a prescribed amount from the reference frequency.

frequency standard—A stable low-frequency oscillator used for frequency calibration. It can generate a fundamental frequency of 50 to 100 kilohertz with a high degree of accuracy. Harmonics of this fundamental are then used as reference points for checking throughout the radio spectrum at 50- or 100-kilohertz intervals.

frequency swing—The instantaneous departure of the emitted wave from the center frequency when its frequency is modulated.

frequency synthesizer—A frequency source of high accuracy generally characterized by the fact that the output frequency is composed of two components. The frequency steps, mostly decadic, are derived from the crystal-stabilized frequency standard and the variable frequency of a free-running oscillator which fills in between these steps. The simplest method of frequency synthesis is to derive standard frequencies from a crystal-controlled frequency by harmonic generation and frequency division.

frequency tolerance—The maximum permissible deviation with respect to the reference frequency of the corresponding characteristic frequency of an emission. Expressed in percent or in hertz.

frequency translation—The transfer *en bloc* of signals occupying a definite frequency band, such as a channel or group of channels, from one position in the frequency spectrum to another in such a way that the arithmetic frequency difference of the signals within the band is unaltered.

frequency tripler—An amplifier whose output circuit is resonant to the third harmonic of the input signal. The output frequency is three times the input frequency.

frequency-type telemeter — A telemeter which employs the frequency of a periodically recurring electric signal as the translating means.

frequency-wavelength relation — For radio waves, the frequency in hertz is equal to approximately 300,000,000 divided by the wavelength in meters. The wavelength in meters is equal to approximately 300,000-000 divided by frequency in hertz or 300 divided by frequency in megahertz.

Fresnel—A little-used unit of frequency equal to 10^{12} hertz.

Fresnel lens—A thin lens constructed to have the optical properties of a much thicker lens.

Fresnel loss—*See* Surface Reflection.

Fresnel region—The region between an antenna and the Fraunhofer region.

Fresnel zone—1. An area selected in the aperture of a radiating system so that radiation from all parts of the system reaches some point at which it is desired at a common phase within 180°. 2. A circular zone about the direct path between a transmitter and a receiver at each radius that the distance from a point on this circle to the receiving point has a path length that is some multiple of a half-wavelength longer than the direct path.

frictional electricity—Electric charges produced by rubbing one material against another.

frictional error—1. Applied to pickups, the difference in values measured in percent of full scale before and after tapping, with the measurand constant.

frictional loss—The loss of energy due to friction between moving parts.

frictional machine—Also called a static machine. A device for producing frictional electricity.

friction effects—The difference in resistance or output between readings obtained prior to and immediately after tapping an instrument while applying a constant stimulus. Particularly applicable to potentiometric transducers.

friction error—A change in a reading originally taken in the absence of vibration that occurs after a transducer is tapped or dithered to remove internal friction.

friction-free calibration (transducer) — Calibration under conditions minimizing the effect of static friction often obtained by dithering.

friction tape—A fibrous tape impregnated with a sticky, moisture-resistant compound which provides a protective covering or insulation.

fringe area—The area just beyond the limits of the reliable service area of a television transmitter. Signals are weak and erratic, requiring the use of high-gain directional receiving antennas and sensitive receivers for satisfactory reception.

fringe howl—A squeal or howl heard when some circuit in a receiver is on the verge of oscillation.

fritting—A type of contact erosion in which an electrical discharge makes a hole through the contact film and produces molten matter that is drawn through the hole by electrostatic forces and then solidifies and forms a conducting bridge.

Frohlich high-temperature breakdown theory—A thermal mechanism for breakdown in which electrons rather than ions carry the current. The necessary number of conduction electrons is produced by thermal excitation of the electrons in impurity and imperfection levels.

Frohlich low-temperature breakdown theory—Also called the high-energy criterion. Similar to the Von Hippel theory, except that an electron energy distribution is assumed. Only a few electrons on the high-energy tail of the distribution must gain the necessary critical energy.

front contact—A movable relay contact which closes a circuit when the associated device is operated.

front end—The section of a tuner or receiver which is used to select the desired station from either the a-m, f-m, or tv band, and to convert the r-f signal to i-f. To do its job properly, a front end requires a high-gain, low-noise r-f stage, a mixer, and an oscillator. The degrees to which a desired station can be received without interference and without adding noise is expressed by sensitivity, selectivity, and signal-to-noise ratio.

front-end rejection—A db expression of the relative ability of a receiver network to reject signals outside the tuned bandwidth.

front porch—In the composite television signal, that portion of the synchronizing signal (at the blanking or black level) preceding the horizontal-sync pulse at the end of each active horizontal line. The standard EIA signal is 1.27 microseconds in duration.

front projection—A system of picture enlargement using an opaque reflective screen. The projector and viewers are on the same side of the screen.

front-surface mirror—An optical mirror on which the reflecting surface is applied to the front of the mirror instead of the back.

front-to-back ratio—Also called front-to-rear ratio. 1. The ratio of power gain between the front and rear of a directional antenna. 2. Ratio of signal strength transmitted in a forward direction to that transmitted in a backward direction. For receiving antennas, the ratio of received-signal strength when the source is in the front of the antenna to the received-signal strength when the antenna is rotated 180°.

front-to-rear ratio—*See* Front-to-Back Ratio.

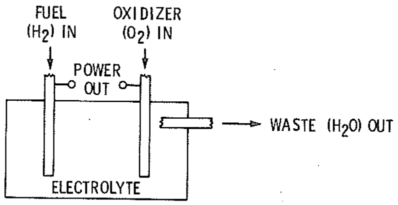
fruit—*See* Fruit Pulse.

fruit pulse—Also called fruit. Radar beacon system video display of a synchronous beacon return which results when several interrogator stations are located within the same general area. Each interrogator receives its own interrogated reply as well as many synchronous replies resulting from interrogation of the airborne transponders by other ground stations.

F-scan—*See* F-Display.

F-scope—*See* F-Display.

fsk—*See* Frequency-Shift Keying.



Fuel cell.

fuel cell—An electrochemical generator in which the chemical energy from the reaction of air (oxygen) and a conventional fuel is converted directly into electricity. A fuel cell differs from a battery in that it uses hydrocarbons (or some derivative such as hydrogen) for fuel, and it operates continuously as long as fuel and air are available.

full duplex—A method of operation of a communication circuit in which each end can simultaneously transmit and receive. When used on a radio circuit, duplex operation requires two frequencies.

full-duplex operation—Simultaneous operation in opposite directions in a telegraph system.

full excursion—The application of a measurand, in a controlled manner, over the entire range of a transducer.

fullhouse—A multichannel radio control system in which all controls work to allow the model to fly a complete flight pattern.

full load—The greatest load a piece of equipment is designed to carry under specified conditions.

full-pitch winding—A type of armature winding in which the number of slots between the sides of the coil equals the pole-pitch measure in the slots.

full scale—The total interval over which an instrument is intended to be operated. Also, the output from a transducer when the maximum rated stimulus is applied to the input.

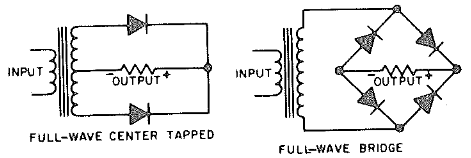
full-scale cycle—The complete range of an instrument, from minimum reading to full scale and back to minimum reading.

full-scale output—The algebraic difference in electrical output between the maximum and minimum values of measurand over which an instrument is calibrated. When the sensitivity slope is given by any other line than the end-point sensitivity, full scale expresses the algebraic difference, for the span of the instrument, which is calculated from the slope of the straight line from which nonlinearity is determined.

full-scale sensitivity—*See* Full-Scale Output.

full-scale value of an instrument—The largest actuating electrical quantity which can be indicated on the scale; or, for an instrument having its zero between the ends of the scale, the sum of the values of the actuating electrical quantity corresponding to the two ends.

full-track recording—Defines the track width as essentially equal to the tape width. Applies to quarter-inch-wide (or less) tape only.



Full-wave rectifier.

full-wave rectifier—A circuit electron tube or other device which uses both positive and negative alternations in an alternating current to produce direct current.

full-wave rectifier tube—A tube containing two sets of rectifying elements, to provide full-wave rectification.

full-wave vibrator—A vibrator having an armature that moves back and forth between two fixed contacts, so as to change the direction of the direct-current flow through a transformer at regular intervals and thereby permit voltage step-up by the transformer. Used in battery-operated power supplies for mobile and marine radio equipment.

function—1. A quantity the value of which depends on the value of one or more other quantities. 2. A specific purpose of an entity, or its characteristic action.

functional device—*See* Integrated Circuit.

functional electronic block—A fabricated device serving a complete electronic function, such as amplification, without other individual components or conducting wires except those required for input, power, and output.

functional interface—An interface between the operating characteristics of equipment such as electrical power and signal characteristics, signal timing, and environmental coupling.

functional parts—Discrete items defined by functional characteristics and dimensions which are not repairable with the use of spare parts (e.g., resistors, capacitors, diodes, potted transformers, permanently sealed batteries, etc.).

function characteristic—The relationship between the output ratio and the shaft position of a precision potentiometer.

function codes—Codes which appear in tape or cards to operate machine functions, such as carriage returns, space, shift, skip, tabulate, etc.

function digit—A coded instruction used in a computer for setting a branch order to link subroutines into the main program.

function generator—A device capable of generating one or more desired waveforms.

functioning time—In a relay, the time that elapses between energization and operation or between de-energization and release.

functioning value—In a relay, the value of applied voltage, current, or power at which operation or release occurs.

function switch—1. A network or system having a number of inputs and outputs. When signals representing information expressed in a certain code are applied to the inputs, the output signals will represent the input information in a different code. 2. In adapters or control units, the switch which determines whether the system plays as a monophonic or stereophonic unit; it may parallel the speakers or cut out one or the other, switch amplifiers from one speaker to the other, reverse channels, etc.

function table—1. A table of values for mathematical function. 2. A hardware device or a computer program which translates one representation of information into another.

function unit—A device which can store a functional relationship and release it continuously or sporadically.

fundamental—*See* Fundamental Frequency.

fundamental component—The fundamental frequency component in the harmonic analysis of a wave.

fundamental frequency—The principal component of a wave; i.e., the component with the lowest frequency or greatest amplitude. It is usually taken as a reference.

fundamental harmonic—The harmonic component with the lowest frequency.

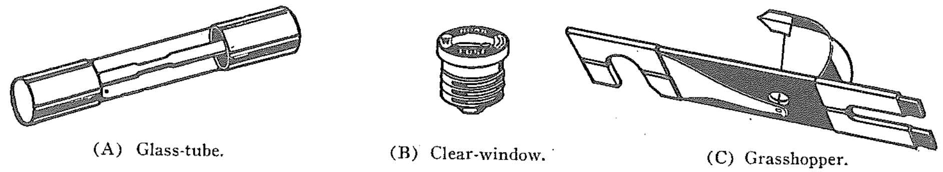
fundamental mode—1. *See* Dominant Mode. 2. Of vibration, the mode having the lowest natural frequency.

fundamental piezoelectric crystal unit—A unit designed to use the lowest resonant frequency for a particular mode of vibration.

fundamental tone—1. In a periodic wave, the component corresponding to the fundamental frequency. 2. In a complex tone, the component tone of lowest pitch.

fundamental units—Units arbitrarily selected to serve as the basis of an absolute system of units.

fundamental wavelength—The wavelength corresponding to the fundamental frequency.



(A) Glass-tube. (B) Clear-window. (C) Grasshopper.

Fuses.

In an antenna, the lowest resonant frequency of the antenna alone, without inductance or capacitance.

funguspro of—To chemically treat a material, component, or unit to prevent the growth of fungus spores.

fuse—A protective device, usually a short piece of wire but sometimes a chemical compound, which melts and breaks the circuit when the current exceeds the rated value.

fuse alarm—A circuit which produces a visual and/or audible signal to indicate a blown fuse.

fuse block—An insulating base on which fuse clips or other contacts for holding fuses are mounted.

fuse box—An enclosed box containing fuse blocks and fuses.

fuse clips—Contacts on the fuse support for connecting the fuse holder into the circuit.

fused disconnect — Generally an air-break switch with a fusing unit in the blade. Used for opening and closing high-voltage circuits.

fused junction—*See* Alloyed Junction.

fused quartz—A glasslike insulating material having exceptional heat and acid resistance.

fused semiconductor—The junction formed by recrystallization on a base crystal from a liquid phase of one or more components and the semiconductor.

fuse filler—Material placed within the fuse tube to aid circuit interruption.

fuse holder—A device for supporting a fuse and providing connections for its terminals.

fuse link—In a fuse, the current-carrying portion which melts when the current exceeds a predetermined value.

Fusestat—Trade name for a time-delay fuse similar to a Fusetron. It has a sized base requiring a permanent socket adapter, which prevents insertion of a fuse or Fusetron of an incorrect rating.

Fusetron—A screw-plug fuse that permits up to 50% overload for short periods of time without blowing.

fuse tube—The insulated tube enclosing a fuse link.

fuse unit—An assembly comprised of a fuse link mounted in a fuse holder, which contains parts and materials essential to the operation of the fuse link.

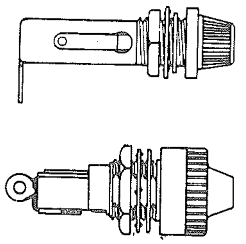
fuse wire—A wire made from an alloy that melts at a relatively low temperature.

fusible resistor—A resistor designed to protect a circuit against overload by opening when the current drain exceeds the design limits.

fusible wire—A wire used in fire-alarm circuits. It is made of an alloy with a low melting point.

fusion—Also called atomic fusion or nuclear fusion. The merging of atomic nuclei, under extreme heat (millions of degrees), to form a heavier nucleus. The fusion of two nuclei of light atoms is accompanied by a tremendous release of energy.

fv—Abbreviation for femtovolt (10^{-15} volt).



Fuse holders.

G

G—1. Symbol for conductance, the grid of a vacuum tube, a generator, or ground. 2. Abbreviation for giga (10^9).

g—Also called G-force. Symbol for the acceleration of a free-falling body due to the earths gravitational pull. Equal to 32.17 feet per second per second.

G/A (ground-to-air)—Communication with airborne objects from the ground.

GA coil—A coil wound with air spaces between its turns and layers to reduce the capacitance.

gage—Also spelled gauge. An instrument or means for measuring or testing. By extension, the term is often used synonymously with transducer.

gage pressure—1. A differential pressure measurement using the ambient pressure as a reference. 2. A pressure in excess of a standard atmosphere at sea level (i.e., 14.7 pounds per square inch).

gage pressure transducer — A pressure transducer that uses ambient pressure as the reference pressure. The sensing element is normally vented to the ambient pressure.

gain—Also called transmission gain. 1. Any increase in power when a signal is transmitted from one point to another. Usually expressed in decibels. Widely used for denoting transducer gain. 2. The ratios of voltage, power, or current with respect to a standard or previous reading.

gain bandwidth product — The product of the closed-loop gain of an operational amplifier and its corresponding closed-loop bandwidth. This product is often constant in operational amplifiers.

gain control—A device for varying the gain of a system or component.

gain margin—The amount of gain change of an operational amplifier at 180° phase-shift angle frequency that would produce instability.

gain-sensitivity control — *See* Differential Gain Control.

gain stability—The extent to which the sensitivity of an instrument remains constant with time. (The property reported in specifications should be instability, which is the maximum change in sensitivity from the initial value over a stated period of time under stated conditions.)

gain-time control—*See* Sensitivity Time Control.

galena—A bluish-gray, crystalline form of lead sulphide often used as the crystal in a variable crystal detector.

galloping ghost — *See* Proportional Control.

galvanic—An early term for current resulting from chemical action, as distinguished from electrostatic phenomena.

galvanic anode—A source of emf for cathodic protection provided by a metal less noble than the one to be protected (i.e., magnesium, zinc, or aluminum as used for cathodic protection of steel).

galvanic cell—An electrolytic cell capable of producing electric energy by electrochemical action.

galvanic corrosion — Accelerated electrochemical corrosion produced when one metal is in electrical contact with another more noble metal, both being in the same corroding medium, or electrolyte, with a current between them. (Corrosion of this type usually results in a higher rate of solution of the less noble metal and protection of the more noble metal.)

galvanic current—An electrobiological term for unidirectional current such as ordinary direct current.

galvanic series—A list of metals and alloys arranged in the order of their relative potentials (ability to go into solution) in a given environment. The table of potentials is arranged with the anodic, or least noble, metals at one end and the cathodic, or more noble, metals at the other. (For marine use, the potentials listed are related to a seawater environment.)

galvanizing—The coating of steel with zinc to retard corrosion.

galvanometer—An instrument for measuring an electric current. This is done by measuring the mechanical motion produced by the electromagnetic or electrodynamic forces set up by the current.

galvanometer constant—The factor by which a certain function of a galvanometer reading must be multiplied to obtain the current in ordinary units.

galvanometer lamp—The lamp that illuminates a movable mirror of the galvanometer in some spectrophotometers. The angle at which the light is reflected to the galvanometer scale depends on the amount of current through the galvanometer coil.

galvanometer recorder (for photographic recording)—A combination of a mirror and coil suspended in a magnetic field. A signal voltage, applied to the coil, causes a light beam from the mirror to be reflected across a slit in front of a moving photographic film.

galvanometer shunt—A resistor connected in parallel with a galvanometer to increase the range of the instrument. The resistor limits the current to a known fraction and thus prevents excess current from damaging the galvanometer.

gamma—A numerical indication of the degree of contrast in a televised image. It is obtained by making a plot of the log of the output magnitude (ordinate) against the log of the input magnitude (abscissa), measured from a point corresponding to some reference black level. Then, take a straight line which approximates this plot over the region of interest and take its slope.

gamma correction—Introduction of a nonlinear output-input characteristic for the purpose of changing the effective value of gamma.

gamma ferric oxide—The magnetic constituent of practically all present-day tapes, in the form of a dispersion of fine acicular particles within the coating.

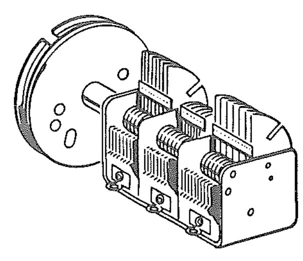
gamma radiation—The radiation of gamma rays.

gamma rays—The emission from certain radioactive substances. They are electromagnetic radiations similar to X-rays, but with a shorter wavelength.

gang—To mechanically couple two or more variable capacitors, switches, potentiometers, or other components together so they can be operated from a single control knob.

gang capacitor—Also called gang tuning capacitor. Two or more variable tuning capacitors mounted on the same shaft and controlled by a single knob, but each capacitor tuning a different circuit. Thus, more than one circuit can be tuned simultaneously by a single control.

gang control—Simultaneous control of several



Gang capacitor.

similar pieces of apparatus with one adjustment knob or other control.

ganged tuning—Simultaneous tuning of two or more circuits with a single mechanical control.

gang punch—To punch information that is identical or constant into all of a group of punch cards.

gang switch—A number of switches mechanically coupled for simultaneous operation, but electrically connected to different circuits. In one common form, two or more rotary switches are mounted on the same shaft and operated by a single control.

gang tuning capacitor—*See* Gang Capacitor.

gap—1. In a magnetic circuit, the portion that does not contain ferromagnetic material (e.g., an air space). 2. The space between two electrodes in a spark gap. 3. The distance between the poles of a recording head.

gap arrester—A type of lightning arrester comprising a number of air gaps in series between metal cylinders or cones.

gap coding—In navigation, a process of communicating by interrupting the transmission of an otherwise continuous signal so that the interruptions form a telegraphic message.

gap depth—The dimension of the gap in a recording head, measured perpendicular to the surface of the head.

gap filler—1. A lightweight radar set used to fill in gaps in the coverage pattern of an early-warning radar net. 2. An auxiliary radar antenna used to fill in gaps in the pattern of the main radar antenna.

gap filling—Electrical or mechanical rearrangement of an antenna array, or the use of a supplementary array, to produce lobes where gaps previously occurred.

gap insulation—Insulation wound in a gap.

gap length—The dimension of the gap of a recording head, measured from one pole face to the other. In longitudinal recording, the gap length is the dimension of the gap in the direction of tape travel.

gap loss—The loss in output attributable to the finite gap length of the reproduce head. The loss increases as the wavelength decreases, amounting to approximately 4 db when the wavelength is equal to twice the gap length, and subsequently increases rapidly toward a complete extinction of output when the wavelength is approximately equal to 1.15 times the gap length.

gap motor—A spark-gap drive motor.

gap scatter—In a computer, the deviation from true vertical alignment of the gaps of the magnetic readout heads for the several parallel tracks.

gap width—The dimension of the gap, measured in the direction parallel to the head surface and pole faces. The gap width of the record head governs the track width. The gap widths of reproduce heads are sometimes made appreciably less than those of the record heads to minimize tracking errors.

garbage—In a computer, a slang term for unwanted and meaningless information carried along in storage. Sometimes called hash.

garble—Faulty transmission, reception, or encoding which renders the message incorrect or unreadable.

garnet maser—*See* Ferromagnetic Amplifier.

garter spring—In facsimile, the spring fastened around the drum to hold the record sheet or copy in place.

gas—One of the three states of matter. An aeriform fluid having neither independent shape nor volume, but tending to spread out and occupy the entire enclosure in which it is placed. Gases are formed by heating a liquid above its boiling point.

gas amplification—Ratio of the charge collected to the charge liberated by the initial ionizing of the gas in a radiation counter.

gas-amplification factor—Ratio of radiant or luminous sensitivities with and without ionization of the gas contained in a gas phototube.

gas cleanup—The tendency of many gas-filled tubes to lose their gas pressure and hence become inoperable. This occurs when the ions of gas are driven at high velocity into the metal parts or the glass envelope of the tube where they form stable compounds and are lost as far as the tube is concerned.

gas current—The current which flows in the grid circuit of a vacuum tube when gas ions within the tube are attracted by the grid.

gas detector—An instrument used to indicate the concentration of harmful gases in the air.

gas diode—A tube having a hot cathode and an anode in an envelope containing a small amount of an inert gas or vapor. When the anode is made sufficiently positive, the electrons flowing to it collide with gas atoms and ionize them. As a result, the anode current is much greater than that for a comparable vacuum diode.

gas-electric drive—A self-contained power-conversion system comprising an electric generator driven by a gasoline engine. The generator in turn supplies power to the driving motor or motors.

gaseous electronics—The field of study involving the conduction of electricity through gases and a study of all atomic-scale collision phenomena.

gaseous tube—An electronic tube into which a small amount of gas or vapor is introduced after the tube has been evacuated. Ionization of the gas molecules during operation of the tube affects its operating characteristics.

gaseous-tube generator—A power source comprising a gas-filled electron-tube oscillator and a power supply, plus associated controls.

gas-filled cable—A coaxial or other type of cable containing gas under pressure which serves as insulation and keeps out moisture.

gas-filled lamp—A tungsten-filament lamp containing nitrogen or an inert gas such as argon.

gas-filled radiation-counter tube—A gas tube used for the detection of radiation. It operates on the principle that radiation will ionize a gas.

gas-filled tube rectifier—A rectifier tube in which a unidirectional flow of electrons from a heated electrode ionizes the inert gas within the tube. In this way, rectification is accomplished.

gas focusing—Also called ionic focusing. The use of an inert gas to focus the electron beam in a cathode-ray tube. Beam electrons ionize the gas molecules, forming a core of positive ions along the beam path which tends to attract beam electrons, making the beam more compact.

gasket-sealed relay—A relay in an enclosure sealed with a gasket.

gas laser—A laser where the active medium is a discharge in a gas within a glass or quartz tube that has a Brewster window at each end. This gas can be excited by a high-frequency oscillator or by a direct current flowing between electrodes inside the tube to pump the medium so as to obtain a population inversion.

gas magnification—The increase in current through a phototube due to ionization of the gas within the tube.

gas maser—A maser in which the microwave electromagnetic radiation interacts with the molecules of a gas such as ammonia. Use is limited chiefly to highly stable oscillator applications, as in atomic clocks.

gas noise—Electrical noise produced by erratic motion of gas molecules in gas or partially evacuated vacuum tubes.

gas-phase laser—A continuous-wave device for general experimental work with coherent light. It employs a resonator made up of a fused-silica plasma tube 60 cm long having internal, multilayer, dielectric-coated confocal reflectors of optical-grade fused silica.

gas phototube—A phototube into which a quantity of gas has been introduced, usually to increase its sensitivity.

gas ratio—The ratio of the ion current in a tube to the electron current that produces it.

gassiness—The presence of unwanted gas in a vacuum tube, usually in relatively small amounts. It is caused by leakage from outside the tube or by evolution from its inside walls or elements.

gassing—1. Evolution of a gas from one or more electrodes during electrolysis. 2. The production of gas in a storage battery when the charging current is continued after the battery has been completely charged.

gassy tube—*See* Soft Tube.

gaston—A modulator that produces a random-noise modulation signal from a gas tube. It may be attached to any standard aircraft communications transmitter to provide a counterjamming modulation.

gas tube—A partially evacuated electron tube containing a small amount of gas. Ionization of the gas molecules is responsible for the current flow.

gas-tube relaxation oscillator—A relaxation oscillator in which the abrupt discharge is provided by the breakdown of the gas in the tube.

gas X-ray tube—An X-ray tube in which electron emission from the cathode is produced by bombarding it with positive ions.

gate—1. A circuit having two or more inputs and one output, the output depending upon the combination of logic signal at the inputs. There are four gates, called AND, OR, NAND, and NOR. The definitions assume postive logic is used. In computer work, a gate is often called an AND circuit. 2. A signal used to trigger the passage of other signals through a circuit. 3. An electrode in a field-effect transistor. 4. An output element of a cryotron.

gate circuit—A circuit that passes a signal only when a gating pulse is present.

gate-controlled switch—Also called gate turn-off switch. A three-junction, three-terminal, solid-state device, constructed very much like a silicon controlled rectifier except that it has a turn-off ability, which is controlled by a negative-current pulse applied to the gate.

gate current—Instantaneous current flowing between the gate and cathode of a silicon controlled rectifier.

gate current for firing—Gate current required to fire a silicon controlled rectifier when the anode is at +6 volts with respect to the cathode and with the device at stated temperature conditions.

gated-beam detector—A single-stage f-m detector using a gated-beam tube.

gated-beam tube—A five-element tube in which the electrons flow in a beam between the cathode and plate. A small increase in voltage on the limiter grid will cut off the plate current, and further increases will have a negligible effect on it.

gated buffer—A low-impedance inverting driver circuit that may be used as a line driver for pulse differentiation or in multivibrators.

gated flip-flop—One that has a steering circuit that prevents both flip-flop outputs from becoming "0" at the same time. Alternating-current input pulses must be used to prevent the flip-flop from oscillating. This situation can arise if both input lines are made high simultaneously.

gated sweep—Sweep in which the duration as well as the starting time is controlled to exclude undesired echoes from the indicator screen.

gated transistor—A transistor in which a gate electrode covers the emitter and collector junctions. This allows the application of an electric field at the surface of the base region.

gate electrode—The control electrode of a FET, MOST controlled rectifier, or triac.

gate generator—A circuit or device used to produce one or more gate pulses.

gate impedance—The impedance of a gate winding in a magnetic amplifier.

gate power dissipation — The power dissipated between the gate and cathode terminals of a silicon controlled rectifier.

gate-producing multivibrator—A rectangular-wave generator that produces a single positive or negative gate voltage only when triggered by a pulse.

gate pulse—A pulse that enables a gate circuit to pass a signal. The gate pulse generally has a longer duration than the signal to insure time coincidence.

gate signal—That signal generated by some form of delay circuit required in connection with beam switching, automatic following, the application of agc to a selected echo, and many other purposes.

gate trigger current—In a controlled rectifier, the minimum gate current, for a given anode-to-cathode voltage, required to switch the rectifier on.

gate trigger voltage—In a controlled rectifier, the gate voltage that produces the gate trigger current.

gate tube—A tube which does not operate unless two signal voltages, derived from two independent circuits, are applied simultaneously to two separate electrodes.

gate turn-off current—In a controlled rectifier, the minimum gate current, for a given collector current in the on state, required to cause the rectifier to switch off.

gate turn-off switch — *See* Gate-Controlled Switch.

gate turn-off voltage—In a controlled rectifier, the gate voltage required to produce the gate turn-off current.

gate voltage—1. The voltage across the gate-winding terminals of a magnetic amplifier. 2. The instantaneous voltage between gate and cathode of a silicon controlled rectifier with anode open.

gate winding—The reactor winding that produces the gating action in a magnetic amplifier.

gating—1. Selecting those portions of a wave which exist during certain intervals or which have certain magnitudes. 2. Applying a rectangular voltage to the grid or cathode of a cathode-ray tube, to sensitize it during the sweep time only. 3. Application of a specific waveform to perform electronic switching. *Also see* Blanking.

gating circuit—A circuit that operates as a selective switch and allows conduction only during selected time intervals or when the signal magnitude is within specified limits.

gating pulse—A pulse which modifies the operation of a gate circuit.

gauge—*See* Gage.

gauge pressure—*See* Gage Pressure.

gauss — The centimeter-gram-second electromagnetic unit of magnetic induction. One gauss represents one line of flux (one maxwell) per square centimeter.

Gaussian distribution — Also called normal distribution. A density function of a population which is bell-shaped and symmetrical and which is completely defined by two independent parameters, the mean and the standard deviation.

Gaussian noise — Unwanted electrical disturbances or perturbations described by a probability density function that follows a normal law of statistics.

Gaussian random vibration — *See* Random Vibration.

gaussmeter—An instrument that provides direct readings of magnetic field density (flux density) by virtue of the interaction with an internal magnetic field.

Gauss's theorem—The summation of the normal component of the electric displacement over any closed surface is equal to the electric charge within the surface.

GCA—Abbreviation for ground-controlled approach.

GCI—Abbreviation for ground-controlled interception.

GCT or Gct — Abbreviation for Greenwich civil time.

G-display — Also called G-scan or G-scope. In radar, a rectangular display in which a target appears as a laterally-centralized blip on which wings appear to grow as the target approaches. Horizontal and vertical aiming errors are indicated by horizontal and vertical displacement of the blip.

gear—An element shaped like a toothed wheel which engages one or more similar wheels. The energy transmitted can be stepped up or down by making the driven gears of different sizes.

geared synchro system—A system in which the transmitting and receiving synchros turn at a higher speed than the input and output shafts. Geared systems are generally used when a high degree of accuracy is required.

gearmotor—A train of gears and a motor used for reducing or increasing the speed of the driven object.

Geiger counter—Also called Geiger-Mueller or G-M counter. A radiation detector that uses a Geiger-Mueller counter tube, an amplifier, and an indicating device. The tube consists of a thin-walled gas-filled metal cylinder with a projecting electrode. Nuclear particles enter a window in the metal cylinder and temporarily ionize the gas, causing a brief pulse discharge. These pulses, which appear at the projecting electrode, are amplified and indicated visibly or audibly.

Geiger-Mueller counter—*See* Geiger Counter.

Geiger-Mueller counter tube—A radiation-counter tube designed to operate in the Geiger-Mueller region.

Geiger-Mueller region—Also called Geiger region. The voltage interval in which the pulse size is independent of the number of primary ions produced in the initial ionizing event.

Geiger-Mueller threshold — Also called Geiger threshold. The lowest voltage at which all pulses produced in the tube by any ionizing event are of the same size regardless of the size of the primary ionizing event. This threshold is the start of the Geiger region where the counting rate does not substantially change with applied voltage.

Geiger region—*See* Geiger-Mueller Region.

Geiger threshold — *See* Geiger-Mueller Threshold.

Geissler tube—A gas filled dual-electrode discharge tube that glows when electric current passes through the gas.

gel—A material composed of a solid held in a liquid.

genemotor—A type of dynamotor having two armature windings. One winding serves as the driving motor and operates from the vehicle battery. The other winding functions as a high-voltage d-c generator for operation of mobile equipment.

general-purpose computer—A computer designed to solve a wide variety of problems, the exact nature of which may have been unknown before the computer was designed.

general-purpose motor—A motor of 200 hp or less and 450 rpm or more, rated for continuous operation, having standard ratings, and suitable for use without restriction to a particular application.

general-purpose relay — A relay that is adaptable to a variety of applications.

general rate—The amount of time taken by the creation of electron-hole pairs in a semiconductor.

general routine — A computer routine designed to solve a general class of problems, but when appropriate parametric values are supplied, it specializes in a specific problem.

generated noise—1. In potentiometric transducers, the noise which is attributable to causes such as the generation of emf when dissimilar metals are rubbed against each other, or the emf resulting from the thermocouple effects at points where dissimilar metals are joined.

generating electric field meter—Also called a gradient meter. A device for measuring the potential gradient at the surface of a conductor. A flat conductor is alternately exposed and then shielded from the electric field to be measured. The resultant current in the conductor is then rectified and used as the measure.

generating magnetometer—Also called earth inductor. A magnetometer which measures an electric field by the amount of emf generated in a coil rotated in the field.

generating station—An installation that produces electric energy from chemical, mechanical, hydraulic, or some other form of energy.

generating voltmeter—Also called a rotary voltmeter. A device which measures voltage. A capacitor is connected across the voltage, and its capacitance is varied cyclically. The resultant current in the capacitor is then rectified and used as a measure.

generation rate—The time rate of creation of electron-hole pairs in a semiconductor.

generator—1. Symbolized by G. A rotating machine which converts mechanical energy into electrical energy. 2. An electronic device which converts d-c voltage to alternating current of the desired frequency and waveshape.

generator efficiency—1. In a generator, the ratio between the power required to drive the generator and the output power obtained from it. 2. In a thermoelectric couple, the ratio of the electrical power output to the thermal power input. It is an idealized efficiency assuming perfect thermal insulation of the thermoelectric arms.

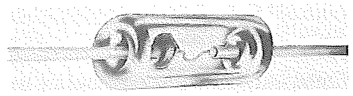
generator voltage regulator—A regulator which maintains or varies the voltage of a synchronous generator, capacitor motor, or direct-current generator at or within a predetermined value.

geodesic—The shortest line between two points on a given surface.

geometric distortion—In television, any geometric dissimilarity between the original scene and reproduced image.

geometric mean—The square root of the product of two quantities.

george box — An amplitude-sensitive device employed in an i-f amplifier. It rejects jamming signals of insufficient amplitude to operate its circuits; however, jamming signals having sufficient amplitude are not affected.

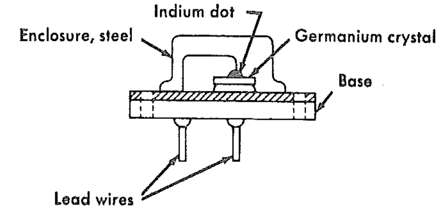


Germanium diode.

germanium diode—A rectifier or detector made from a germanium crystal.

germanium (Ge) — A brittle, grayish-white metallic element having semiconductor properties. Widely used in transistors and crystal diodes. Its atomic number is 32.

germanium transistor — A transistor in which germanium is the semiconducting material.



Germanium (power) transistor.

German silver—Usually called nickel silver. A silverish alloy of copper, zinc, and nickel.

getter—An alkali metal introduced into a vacuum tube during manufacture. It is fired after the tube has been evacuated, to react chemically with and eliminate any remaining gases. The getter then remains inactive inside the tube. The silvery deposit sometimes seen on the inside of the glass envelope is due to getter firing.

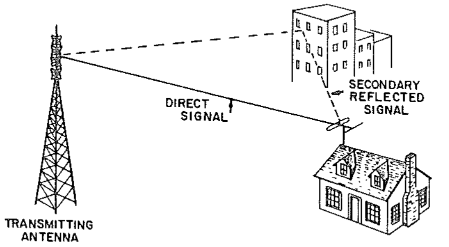
G force—*See* g.

G/G (ground-to-ground) — Communication between two points on the ground.

ghost—*See* Ghost Image.

ghost image—Also called ghost. An undesired duplicate image offset somewhat from the desired image as viewed on a television screen. It is due to a reflected signal traveling over a longer path and, hence, arriving later than the desired signal. It may be eliminated by the use of a directional antenna array which receives signals over only one path.

ghost pulse—*See* Ghost Signal.



Ghost signal.

ghost signal—Also called ghost pulse. An unwanted signal on the screen of a radar indicator. Echoes which experience multiple reflections before reaching the receiver are an example.

giant grid—An extensive regional or national system of backbones and networks.

giant ties—*See* Interconnection.

Gibson girl—A portable, hand-operated transmitter used by pilots forced down at sea.

giga—A prefix meaning one billion, or 10^9.

gigacycle—One kilomegacycle, or one billion cycles. An obsolete term. The currently preferred term is gigahertz.

gigahertz—A term for 10^9 cycles per second. Used to replace the more cumbersome and obsolete term kilomegacycle. Abbreviated GHz.

gigawatt—Abbreviated GW. One thousand megawatts (10^9 watts).

gigohm—One thousand megohms (10^9 ohms).

gilbert—A cgs unit of the magnetomotive force required to produce one maxwell of magnetic flux in a magnetic circuit of unit reluctance. Magnetomotive force in gilberts $= 10/4\pi$ ampere-turns.

gilbert per centimeter—The practical cgs unit of magnetic intensity. Gilberts per centimeter are the same as oersteds.

Gill-Morrell oscillator—A retarding-field oscillator in which the oscillation frequency depends not only on the electron-transit time within the tube, but also on the associated circuit parameters.

gill selector—A slow-acting telegraph sender and calling key for selective signaling.

gimbal—A mechanical frame having two perpendicularly intersecting axes of rotation.

gimmick—A capacitance formed by twisting two insulated wires together or bringing two conductors into close proximity.

gimp—A slang name given to the extremely flexible wire used in telephone cords and similar equipment. This wire cannot be directly soldered to, as it is a metallic cloth-type material.

Giorgi system—*See* Mksa System of Units.

glass electrode — In electronic pH measurement, an electrode used for determining the potential of a solution with respect to a reference electrode. The calomel type is the most common.

glassiviation—A method of transistor passivation by a pyrolytic glass-deposition technique, whereby silicon semiconductor devices, complete with metal contact systems, are fully encapsulated in glass.

glass-plate capacitor—A high-voltage capacitor in which the metal plates are separated by sheets of glass for the dielectric. The complete assembly is generally immersed in oil.

glass-to-metal seal — An airtight seal between glass and metal parts of an electron tube, made by fusing together a special glass and special metal alloy having nearly the same temperature coefficients of expansion.

glass tube—A vacuum or gaseous tube that has a glass envelope.

glide path—The approach path used by an aircraft making an instrument landing.

glide-path localizer—In an aircraft instrument-landing system, the part which indicates the altitude of the plane and creates a glide path for a blind landing.

glide slope—A radio beam used by pilots to determine their altitude when landing.

glide-slope facility — A radio transmitting facility which provides the glide-slope signals.

G-line—A round wire coated with a dielectric and used to transmit microwave energy.

glint—Also called glitter. A distorted radar-signal echo, which varies in amplitude from pulse to pulse because the beam is being reflected from a rapidly moving object such as an airplane propeller.

glissando — A tone that changes smoothly from one pitch to another.

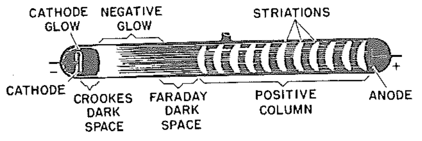
glitch—A form of low-frequency interference appearing as a narrow horizontal bar moving vertically through the television picture. This is also observed on an oscilloscope at the field or frame rate as an extraneous voltage pip moving along the signal at approximately the reference-black level.

glitter—*See* Glint.

glossmeter—A photoelectric instrument for determining the gloss factor of a surface (i.e., the ratio of light reflected in one direction to the light reflected in all directions).

glow discharge—A discharge of electricity through a gas in an electron tube. It is characterized by a cathode glow resulting from a space potential, much higher than the ionization potential of the gas in the vicinity of the cathode.

glow-discharge microphone—A microphone in which the sound waves cause corresponding variations in the current forming a glow discharge between two electrodes.



Glow-discharge tube.

glow-discharge tube—A gas tube that depends for its operation on the properties of a glow discharge.

glow-discharge voltage regulator — A gas tube used for voltage regulation. The resistance of the gas within the tube varies in step with the voltage applied across the tube.

glow lamp — A lamp containing a small amount of gas or vapor. Current between the two electrodes ionizes the gas and causes the lamp to glow but does not provide rectification. Neon gives a red-orange glow, mercury vapor a blue glow, and argon a purple glow.

glow potential—The voltage at which a glow discharge begins in a gas-filled electronic tube as the voltage is gradually increased.

glow switch—An electron tube used in some fluorescent-lamp circuits. It contains two bimetal strips which are closed when heated by the glow discharge.

glow-tube rectifier — Also called a point-plane rectifier. A cold-cathode gas-discharge tube which provides a unidirectional current flow.

glue-line heating—An arrangement of electrodes designed to heat a thin film of material having a high loss factor between alternate layers of materials having a low loss factor.

g_m—Symbol for the mutual conductance or transconductance of a vacuum tube.

G-M counter — Abbreviation for Geiger-Mueller counter.

GMT or Gmt—Abbreviation for Greenwich mean time.

gobo—A dark mat used to shield the lens of a television camera from stray lights.

gold-bonded diode — A semiconductor diode in which a preformed whisker of gold contacts an N-germanium substrate as the junction is formed by millisecond electrical pulses.

gold doping—A technique used to control the lifetime of minority carriers in a diffused-mesa transistor. Gold is diffused into the base and collector regions to reduce the storage time.

gold-leaf electroscope—An apparatus comprising two pieces of gold leaf joined at their upper ends and suspended inside a glass jar. When a charge is applied to the terminal connected to the leaves, they spread apart due to repulsion of the like charges on them.

Goldschmidt alternator — An early radio transmitter. It is a rotating machine employing oscillating circuits in connection with the field and the armature to introduce harmonics in the generated fundamental frequency. Interaction between the stator and rotor harmonics gives a cumulative effect and thereby provides very high radio frequencies.

goniometer—1. In a radio-range system, a device for electrically shifting the directional characteristics of an antenna. 2. An electrical device for determining the azimuth of a received signal by combining the outputs of individual elements of an antenna array in certain phase relationships.

googol — In mathematics, the figure 1 followed by 100 zeros.

goto circuit—A circuit capable of sensing the direction of current. It can be used in majority logic circuits in which the output is either positive or negative, depending on whether the majority of its inputs is positive or negative.

governed series motor—A motor used with teletypewriter equipment. It has a governor for regulating the speed.

governor—1. A motor attachment that automatically controls the speed at which the motor rotates. 2. The equipment which controls the gate or valve opening of a prime mover.

GPI—Abbreviation for ground-position indicator.

graded base transistor — *See* Diffused Base Transistor.

graded filter—A power-supply filter in which the output stage of a receiver or audio amplifier is connected at or near the filter input so that the maximum available d-c voltage will be obtained. The output stage has low gain; therefore, ripple is not too important.

graded-junction transistor—*See* Rate-Grown Transistor.

graded thermoelectric arm — A thermoelectric arm having a composition that changes continuously in the direction of the current.

gradient — The rate at which a variable quantity increases or decreases. For example, potential gradient is the difference of potential along a conductor or through a dielectric.

gradient meter — *See* Generating Electric Field Meter.

gradient microphone — A microphone in which the output rises and falls with the sound pressure. (*Also see* Pressure Microphone.)

gram—A unit of mass and weight in the metric system.

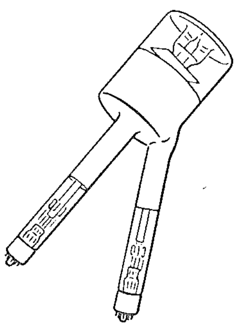
gramme ring—A ring-shaped iron armature around which the coils are wound. Each turn is tapped from the inside diameter of the ring to a commutator segment.

grandfather cycle—The period during which magnetic-tape records are retained before reusing so that records can be reconstructed in the event of loss of information stored on a magnetic tape.

granular carbon—Small particles of carbon used in carbon microphones.

granularity — A characteristic of the output data of a measuring instrument. The measure of granularity is the smallest increment of the output data when it is in a digital form. The smallest increment is also called least count.

graph—A pictorial presentation of the relationship between two or more variables.



Graphechon.

graphechon—An electron tube which utilizes camera-tube principles for storing and recovering electrical signals.

graphical analysis—The use of diagrams and other graphic methods to obtain operating data and answers to scientific or mathematical problems.

graphic instrument—*See* Recording Instrument.

graphite—A finely divided carbon used as a lubricant and in the construction of some carbon resistance elements. The most common use is in so-called lead pencils.

grass — The pattern produced by random noise on an A-scope; it appears as closely spaced, sharp, constantly moving pulses on the base line. *Also see* Random Noise.

graticule—A calibrated screen placed in front of a cathode-ray tube for measurement purposes.

grating—A device for spreading out light or other radiation. It consists of narrow parallel slits in a plate or narrow parallel reflecting surfaces made by ruling grooves on polished metal. The slits or grooves break up the waves as they emerge. (*Also see* Ultrasonic Space Grating *and* Ultrasonic Cross Grating.)

grating reflector—An antenna reflector consisting of an openwork metal structure that resembles a grating.

Gratz rectifier—An arrangement of two rectifiers per phase connected into a three-phase bridge circuit to provide full-wave rectification.

gravity—The force which tends to pull bodies toward the center of the earth, thereby giving them weight. (*Also see* g.)

gravity cell—A primary cell in which two electrolytes are kept separated by differences in specific gravity. It is a modification of the Daniell cell and is now obsolete.

gray body—A radiating body whose spectral emissivity remains the same at all wavelengths. It is in constant ratio of less than unity to the ratio of a black-body radiator at the same temperature.

Gray code—A positional binary number notation in which any two numbers whose difference is one are represented by expressions that are the same except in one place or column and differ by only one unit in that place or column.

gray scale—In a television system, a scale of brightness values ranging from maximum to minimum.

great manual — In an organ, the keyboard normally used for playing the accompaniment to the melody. Also called the accompaniment manual or lower manual.

green-gain control—A variable resistor used in the matrix of a three-gun color television receiver to adjust the intensity of the green primary signal.

green gun—The electron gun the beam of which, when properly adjusted, strikes only the green phosphor dots in the color picture tube.

green restorer—A d-c restorer used in the green channel of a three-gun color-television picture-tube circuit.

green video voltage—The signal voltage that controls the grid of the green gun in a three-gun picture tube.

Greenwich mean time—Abbreviated GMT or Gmt. The mean solar time at the meridian of Greenwich (zero longitude).

grid—1. An electrode having one or more openings for the passage of electrons or ions. (*Also see* Control Grid, Screen Grid, Shield Grid, Space-Charge Grid, *and* Suppressor Grid.) 2. An interconnected system in which high-voltage, high-capacity backbone lines overlay and are connected with networks of lower voltages. 3. A two-dimensional network consisting of a set of equally spaced parallel lines superimposed upon another set of equally spaced parallel lines so that the lines of one set are perpendicular to the lines of the other, thereby forming square areas. The intersections of the lines provide the basis for an incremental location system.

grid battery—Sometimes called a C-battery. A source of energy for supplying a bias voltage to the grid of a vacuum tube.

grid bearing—A bearing made with the reference line to grid north.

grid bias—Also called C-bias. A constant potential applied between the grid and cathode of a vacuum tube to establish an operating point.

grid-bias cell—A small cell used in a vacuum tube circuit to make the grid more negative than the cathode. It provides a voltage, but cannot supply an appreciable amount of current.

grid blocking—Blocking of capacitance-coupled stages in an amplifier because of an accumulated charge of the coupling capacitor as the result of current flow during the reception of large signals.

grid cap—At the top of some vacuum tubes, the terminal which connects to the control grid.

grid capacitor—A capacitor in parallel with the grid resistor or in series with the grid lead of a tube.

grid-cathode capacitance — Capacitance between the grid and the cathode in a vacuum tube.

grid characteristic—The curve obtained by plotting grid-voltage values of a vacuum tube as abscissas against grid-current values as ordinates on a graph.

grid circuit—The circuit connected between the grid and cathode, and forming the input circuit of a vacuum tube.

grid-circuit tester — A tester designed to measure the grid resistance of vacuum tubes without discriminating between the type or polarity of impedance.

grid clip—A spring clip used for making a connection to the top-cap terminal of some vacuum tubes.

grid conductance—The in-phase component of the alternating grid current divided by the alternating grid voltage, all other electrode voltages being maintained constant.

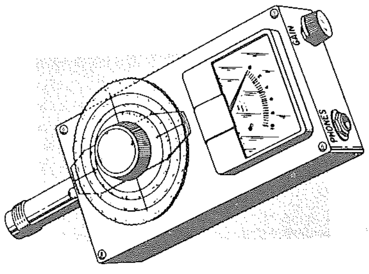
grid-controlled mercury-arc rectifier — A mercury-arc rectifier employing one or more electrodes exclusively for controlling start of the discharge.

grid-controlled rectifier—A triode mercury-vapor rectifier tube in which the grid determines the instant at which plate current starts to flow during each cycle, but does not determine how much current will flow.

grid-control tube — A mercury-vapor–filled thermionic vacuum tube with an external grid control.

grid current—The current which flows in the grid-to-cathode circuit of a vacuum tube. It is usually a complex current made up of several currents having a variety of polarities and impedances.

grid detection—Detection by rectification in the grid circuit of a vacuum tube.



Grid-dip meter.

grid-dip meter—A multiple-range oscillator incorporating a meter in the grid circuit to indicate grid current. The meter is so named because its reading dips (reads a lower grid current) whenever an external resonant circuit is tuned to the oscillator frequency.

grid dissipation—The power lost as heat at the grid of a tube.

grid-drive characteristic—The relationship between the electrical or light output of an electron tube and the control-electrode voltage measured from cutoff.

grid driving power—The average product of the instantaneous value of grid current and the alternating component of grid voltage over a complete cycle.

grid emission—Electron or ion emission from the grid of an electron tube.

grid-glow tube — A glow-discharge, cold-cathode tube in which one or more control electrodes initiate the anode current, but do not limit it except under certain conditions.

gridistor—A field-effect transistor which uses the principle of centripetal striction and has a multichannel structure, combining advantages of both field-effect transistors and minority-carrier injection transistors.

grid leak—A high resistance connected across the grid capacitor or between the grid and cathode. It provides a direct-current path, to limit the accumulation of a charge on the grid.

grid-leak capacitor—A small capacitor connected in a vacuum-tube grid circuit, together with a resistor, to produce grid bias.

grid-leak detector—A triode or multielectrode tube in which rectification occurs because of electron current through a high resistance in the grid circuit. The voltage associated with this flow appears in amplified form in the plate circuit.

grid limiting—The use of grid-current bias derived from the signal, through a large series grid resistor, in order to cut off the plate current and consequently level the output wave for all input signals above a critical value.

grid locking—Faulty tube operation in which excessive grid emission causes the grid potential to become continuously positive.

grid modulation—Modulation produced by application of the modulating voltage to the control grid of any tube in which the carrier is present. Modulation in which the grid voltage contains externally generated pulses is called grid-pulse modulation.

grid neutralization—A method of neutralizing an amplifier. A portion of the grid-to-cathode alternating-current voltage is shifted 180° and applied to the plate-to-cathode circuit through a neutralizing capacitor.

grid north—An arbitrary reference direction used with the grid system of navigation.

grid-pool tank—A grid-pool tube having a heavy metal envelope somewhat resembling a tank in appearance.

grid-pool tube—A gas discharge tube having a mercury-pool cathode, one or more anodes, and a control electrode or grid to control the start of current. *Also see* Excitron *and* Ignitron.

grid-pulse modulation—Modulation produced in an amplifier or oscillator by application of one or more pulses to a grid circuit.

grid pulsing—Method of controlling the operation of a radio-frequency oscillator. The oscillator-tube grid is biased so negatively that no oscillation occurs, even at full plate voltage, except when this negative bias is removed by application of a positive voltage pulse to the grid.

grid resistor—A general term that denotes any resistor in the grid circuit.

grid return—An external conducting path for the return of grid current to the cathode.

grid suppressor—A resistor, sometimes connected between the control grid and the external circuit of an amplifier, to prevent parasitic oscillations caused by stray-capacitance feedback.

grid swing—The total variation in grid-to-cathode voltage from the positive peak to the negative peak of the applied-signal voltage.

grid-to-cathode capacitance—The direct capacitance between the grid and cathode of a vacuum tube.

grid-to-plate capacitance—Designated C_{gp}. The direct capacitance between the grid and plate in a vacuum tube.

grid-to-plate transconductance—The mutual conductance, or ratio of plate-current to grid-voltage changes, in a vacuum tube.

grid voltage—The voltage between the grid and cathode of a tube.

grid-voltage supply—The means for supplying, to the grid of an electron tube, a potential which is usually negative with respect to the cathode.

grommet—An insulating washer, usually of rubber or plastic, inserted through a hole in a chassis or panel to prevent a wire from touching the sides.

groove—In mechanical recording, the track inscribed in the record by a cutting or embossing stylus, including undulations or modulations caused by vibration of the stylus. In stereo discs, its cross section is a right-angled triangle, with each side at a 45° angle to the surface of the record; information is cut on both sides of the groove.

groove angle—In disc recording, the angle between the two walls of an unmodulated groove in a radial plane perpendicular to the surface of the recording medium.

groove shape—In disc recording, the contour of the groove in a radial plane perpendicular to the surface of the recording medium.

groove speed—In disc recording, the linear speed of the groove with respect to the stylus.

ground—1. A metallic connection with the earth to establish ground potential. 2. The voltage reference point in a circuit. There may or may not be an actual connection to earth, but it is understood that a point in the circuit said to be at ground potential could be connected to earth without disturbing the operation of the circuit in any way.

ground absorption—The loss of energy during transmission because of the radio waves dissipated to ground.

ground bus—A conductor, usually large-diameter wire, that connects a number of points to one or more grounding electrodes.

ground check (base-line check)—1. A procedure followed prior to the release of a radiosonde in order to obtain the temperature and humidity correction for the radiosonde system. 2. Any instrumental check prior to the ground launch of an airborne experiment.

ground clamp—A clamp used for connecting a grounding conductor (ground wire) to a grounded object such as a water pipe.

ground clutter—The pattern produced on the screen of a radar indicator by undesired ground return.

ground conduit—A conduit used solely to contain one or more grounding conductors.

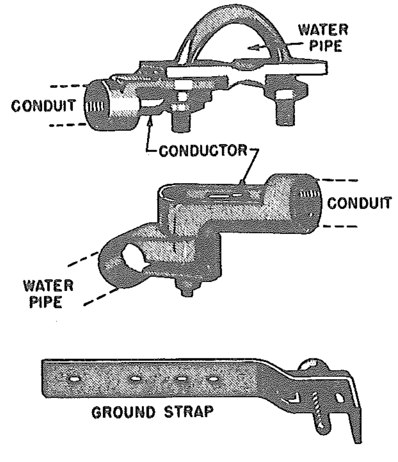
ground-controlled approach — Abbreviated GCA. A ground radar system providing information with which aircraft approaches can be directed by radio.

ground-controlled interception — Abbreviated GCI. A radar system used for directing an aircraft to intercept enemy aircraft.

ground current—*See* Earth Current.

ground dielectric constant—The dielectric constant of the earth at a given location.

ground distance—The great-circle component of distance from one point to another at mean sea level.



Ground clamps.

grounded—Connected to the earth, or to some conducting body in place of the earth.

grounded-base amplifier—*See* Common-Base Amplifier.

grounded cable bond—A cable bond used for grounding the armor and/or sheaths of cables.

grounded capacitance—In a system having several conductors, the capacitance between a given conductor and the other conductors when they are connected together and to ground.

grounded-cathode amplifier—The conventional amplifier circuit. It consists of a tube amplifier in which the cathode is at ground potential at the operating frequency. The input is applied between the control grid and ground, and the output load is between the plate and ground.

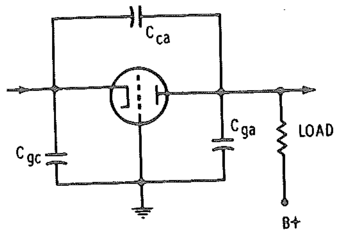
grounded circuit—A circuit in which one conductor or point (usually the neutral conductor or neutral point of transformer or generator windings) is intentionally grounded (earthed) either solidly or through a grounding device.

grounded-collector amplifier—*See* Common-Collector Amplifier.

grounded conductor—A conductor which is intentionally grounded, either directly or through a current-limiting device.

grounded-emitter amplifier—*See* Common-Emitter Amplifier.

grounded-grid amplifier—An electron-tube amplifier circuit in which the control grid is at ground potential at the operating frequency. The input is applied between the cathode and ground, and the output load is between the plate and ground. The grid-to-plate impedance of the tube is in parallel with the load, instead of acting as a feedback path.



Grounded-grid amplifier.

grounded-grid triode—A type of triode designed for use in a grounded-grid circuit.

grounded-grid triode circuit—A circuit in which the input signal is applied to the cathode and the output is taken from the plate. The grid is at r-f ground and serves as a screen between the input and output circuits.

grounded-grid triode mixer—A triode in which the grid forms part of a grounded electrostatic screen between the anode and cathode. It is used as a mixer for centimeter wavelengths.

grounded outlet—An outlet equipped with a receptacle of the polarity type having, in addition to the current-carrying contacts, one ground contact which can be used for the connection of an equipment-grounding conductor.

grounded parts—Parts of a completed installation that are so connected that they are substantially at the same potential as the earth.

grounded-plate amplifier—Also called cathode follower. An electron-tube amplifier circuit in which the plate is at ground potential at the operating frequency. The input is applied between the control grid and ground, and the output load is between the cathode and ground.

grounded system—A system of conductors in which at least one conductor or point (usually the middle wire or neutral point of transformer or generator windings) is intentionally grounded, either solidly or through a current-limiting device.

ground gating—The conversion of pam signals at a telemetry ground station to 50% duty-cycle signals.

ground indication—An indication of the presence of a ground on one or more of the normally ungrounded conductors of a system.

grounding—1. Connecting to ground, or to a conductor which is grounded. 2. A means of referencing electrical circuits to the well-bonded equipotential surface.

grounding conductor—A conductor which, under normal conditions, carries no current, but serves to connect exposed metal surfaces to an earth ground, to prevent hazards in case of breakdown between current-carrying parts and the exposed surfaces. The conductor, if insulated, is colored green with or without a yellow stripe.

grounding connection—A connection used in establishing a ground.

grounding electrode—A conductor embedded in the earth and used for maintaining ground potential on conductors connected to it, or for dissipating into the earth any current conducted to it.

grounding plate — An electrically grounded metal plate on which a person stands in order to discharge any static electricity that may be picked up by his body.

grounding switch—A form of air switch for connecting a circuit or apparatus to ground.

grounding transformer—A transformer intended primarily for the purpose of providing a neutral point for grounding purposes.

ground insulation — The major insulation used between a winding and structural parts at ground potential.

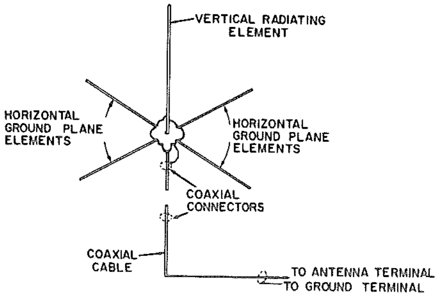
ground loop—The generation of undesirable signals within a ground conductor due to circulation current within the conductor which originates from a second source of potential—frequently as a result of connecting two separate grounds to a signal circuit.

ground lug—A lug for connecting a grounding conductor to a grounding electrode.

ground noise—In recording and reproducing, the residual noise in the absence of a signal. It is usually caused by dissimilarities between the recording and reproducing media, but may also include amplifier noise such as from a tube or noise generated in resistive elements at the input of the reproducer amplifier system.

ground-noise margin—The voltage that may be applied at the ground connection of a logic circuit without causing the circuit to malfunction. It is usually measured by increasing the static ground voltage on a single gate until the logic fails to operate properly.

ground plane—Copper or brass sheet used in interference testing to simulate missile, aircraft, or vehicle frame or skin so that actual installation and grounding conditions may be approximated.



VERTICAL RADIATING ELEMENT
HORIZONTAL GROUND PLANE ELEMENTS
HORIZONTAL GROUND PLANE ELEMENTS
COAXIAL CONNECTORS
COAXIAL CABLE
TO ANTENNA TERMINAL
TO GROUND TERMINAL

Ground-plane antenna.

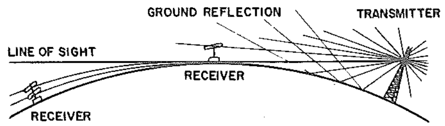
ground-plane antenna—A vertical antenna combined with a turnstile element to lower the angle of radiation. It has a concentric base support and a center conductor that place the antenna at ground potential, even though located several wavelengths above ground.

ground plate—A plate of conductive material buried in the earth to serve as a grounding electrode.

ground-position indicator — Abbreviated GPI. A dead-reckoning computer, similar to an air-position indicator, with provision for taking drift into account.

ground potential—Zero potential with respect to ground or the earth.

ground protective relay — A device which functions on failure of the insulation of a machine, transformer, or other apparatus to ground, or on flashover of a d-c machine to ground.



Ground reflection.

ground-reflected wave—In a ground wave, the component reflected from the earth.

ground resistance — The opposition of the earth to the flow of current through it. Its value depends on the nature and moisture content of the soil. The material, composition, and physical dimensions of the connections to earth, and the electrolytic action present.

ground return—1. In radar, the echoes reflected from the earth's surface and fixed objects on it. 2. A lead from an electronic circuit, antenna, or power line to ground.

ground-return circuit—A circuit which has a conductor (or two or more in parallel) between two points and which is completed through ground or the earth.

ground rod—A steel or copper rod driven into the earth to make an electrical contact with it.

ground shift—The variation in signal amplitude at different grounding points because of a voltage drop along a ground line.

ground speed—In navigation, the speed of a vehicle with reference to ground.

ground-support equipment — All ground equipment that is part of a complete weapons system and that must be furnished to insure complete support of the weapon system.

ground-to-air communication — One-way communication from ground stations to aircraft.

ground wave—A radio wave which travels along the earth's surface rather than through the upper atmosphere.

ground wire—A conductor leading to an electric connection with the earth.

group frequency—The number of sets or groups of waves passing a given point in one second.

grouping—Nonuniform spacing between the grooves of a disc recording.

group loop—A source of interference when a system is grounded improperly at several points.

group modulation—The process by which a number of channels, already separately modulated to a specific frequency range, are again modulated to shift the group to another range.

group velocity—1. Of a traveling plane wave, the velocity of propagation of the envelope delay is approximately constant. It is equal to the reciprocal of the envelope delay per unit length. (Group velocity differs from phase velocity in a medium in which the phase velocity varies with the frequency.) 2. The velocity of propagation of a pulse or a group of waves.

Grove cell—A primary cell with a platinum electrode submerged in an electrolyte of nitric acid within a porous cup, surrounded by a zinc electrode in an electrolyte of sulphuric acid. This cell normally operates on a closed circuit.

growler—An electromagnetic device for locating short-circuited coils and for magnetizing or demagnetizing objects. So called because of the growling noise it makes when indicating a short circuit. It consists essentially of two field poles arranged as in a motor.

grown-diffused transistor — A transistor made by combining the diffusion and double-doped techniques. Suitable N- and P-type impurities are added simultaneously to the melt while the crystal is being grown. Subsequently, the base region is formed by diffusion as the crystal grows.

grown junction—The boundary between P- and N-type semiconducting materials. It is produced by varying the impurities during the growth of a crystal from the melt. Such junctions have strong rectifying properties, the forward current being obtained when P is positive to N.

grown-junction photocell — A photodiode made of a small bar of semiconductor material that has a PN junction at right angles to its length and an ohmic contact at each end of the bar.

grown-junction transistor—A transistor in which junctions are formed by adding impurities to the melt while the crystal is being grown.

G-scan—*See* G-Display.

G-scope—*See* G-Display.

guard band—1. Also called interference-guard band. A frequency band left vacant between two channels to safeguard against mutual interference. 2. The unused chip surface area which by virtue of physical spacing serves to isolate functional elements in a printed circuit or an integrated circuit. Also refers to the consideration given instrumentation precision in electrical testing.

guard circle—An inner concentric groove on disc records. It prevents the pickup from being thrown to the center of the record and possibly damaged.

guarded input—An input that has a third terminal which is maintained at a potential near the input-terminal potential for a single-ended input, or near the mean input potential for the differential input. It is used to shield the entire input circuit.

guarded motor — An open motor in which all openings given direct access to live or rotating parts (except smooth shafts) are limited in size by the structural parts or by screens, grilles, expanded metal, etc., to prevent accidental contact with such parts. Such openings shall not permit the passage of a cylindrical rod ½ inch in diameter.

guard ring—A metal ring placed around a charged terminal or object to distribute the charge uniformly over the surface of the object.

guard shield—A shield surrounding the input circuit of an amplifier.

guard wire—A grounded wire used frequently where high-tension lines cross a thoroughfare. Should a line break, it will contact the guard wire and be grounded.

Gudden-Pohl effect—The momentary illumination produced when an electric field is applied to a phosphor previously excited by ultraviolet radiation.

guidance—Control of a missile or vehicle from within by a person, a preset or self-reacting automatic device, or a device that reacts to outside signals.

guidance system—A system which measures and evaluates flight information, correlates it with target data, and converts the resultant into the parameters necessary to achieve the desired flight path.

guided ballistic missile—A ballistic missile which is guided during the powered portion of the trajectory and follows a free ballistic path during the remainder.

guided missile—An unmanned vehicle moving above the surface of the earth, the trajectory or flight path of which is capable of being altered by an external or internal mechanism.

guided propagation — A type of radio-wave propagation in which radiated rays are bent excessively by refraction in the lower layers of the atmosphere. This bending creates an effect much as if a duct or a wave guide has been formed in the atmosphere to guide part of the radiated energy over distances far beyond the normal range.

guided wave—A wave in which the energy is concentrated near a boundary (or between substantially parallel boundaries) separating materials of different properties. The direction of propagation is parallel to the boundary.

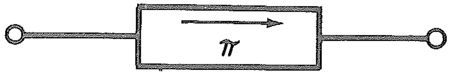
guide wavelength—*See* Waveguide Wavelength.

Guillemin line—A special type of artificial transmission line or pulse-forming network used in radar sets to control the duration of the pulses. It generates a nearly square pulse for use in high-level pulse modulation.

guillotine capacitor—A translatory-motion tuning capacitor consisting of a pair of stators and a sliding plunger in place of a rotor.

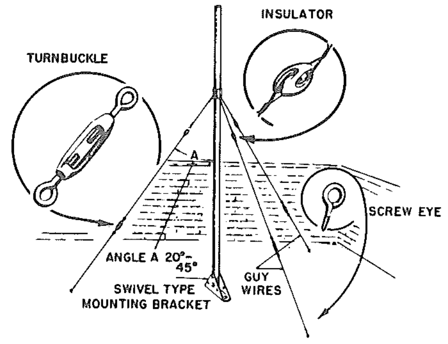
gun-directing radar—Radar used for directing antiaircraft or similar artillery fire.

Gunn effect—Current oscillations that occur at an r-f rate when an electric field of about 3000 v/cm is applied to a short (0.005 inch or less) specimen of N-type gallium arsenide. This effect takes place because electrons under the influence of sufficiently high fields are transferred from high- to low-mobility valleys in the conduction band of GaAs.



Gyrator symbol.

gutta-percha—A natural vegetable gum, similar to rubber, used principally as insulation for wires and cables.



Guy wire.

guy wire—A wire used to brace the mast or tower of a transmitting or receiving antenna system.

gyrator—A two-port circuit element that exhibits a 180° differential, or nonreciprocal, phase shift. The gyrator circuit symbol indicates that an r-f signal transmitted from port 1 to port 2 will undergo a 180° phase shift (arrow direction) relative to an r-f signal transmitted in the reverse direction.

gyro—Abbreviation for gyroscope.

gyrofrequency—The natural frequency at which charged particles rotate around the lines of force of the earth's magnetic field. For electrons, it is 700 to 1,600 kilohertz; for ions, it is in the audio-frequency range.

gyromagnetic—The magnetic properties of rotating electric charges, such as electrons spinning within atoms.

gyropilot—*See* Autopilot.

gyroscope—A rotating device the axle of which will maintain a constant direction, even though the earth is turning under it. It consists of a wheel mounted so that its spinning axis is free to rotate around either of two other axes perpendicular to itself and to each other. When its axle is pointed north, it can be used as a gyrocompass. Abbreviated gyro.

gyroscopic action—An action that causes a mass to turn on an axis perpendicular to the applied torque and to the axis of spin.

gyrostabilized platform—*See* Stable Platform.

G−Y signal—In color television, the green-minus-luminance signal representing primary green minus the luminance, or Y− signal. It is combined with a luminance, or Y− signal outside or inside the picture tube to yield a primary green signal.

H

h—Abbreviation for henry.

H—1. A radar air-navigation system using an airborne interrogator to measure the distance from two ground responder beacons. (*Also see* Shoran.) 2. Symbol for heater or magnetic field strength.

hairpin pickup coil—A hairpin-shaped, single-turn coil for transferring uhf energy.

hairpin tuning bar—A sliding hairpin-shaped metal bar inserted between the two halves of a doublet antenna to vary its electrical length.

halation—Distortion seen as blurred images and caused by reflection of the image rays off the back of a fluorescent screen that is too thick.

half adder—A circuit that will accept two binary input signals and produce corresponding sum and carry outputs. So called because, above the first order, two half adders per order are required when adding two quantities.

half cell—An electrode, submerged in an electrolyte, for measuring single electrode potentials.

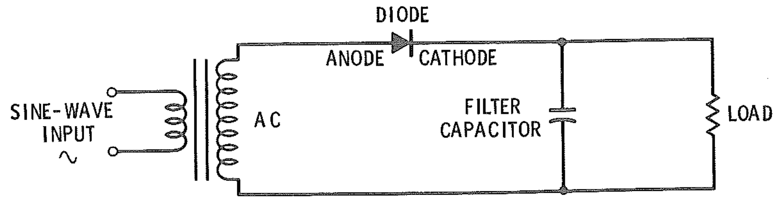
half cycle—The time interval required for the operating frequency to complete one half, or 180°, of its cycle.

half-duplex circuit—A circuit which permits one-direction electrical communications between stations. Technical arrangements may permit operation in either direction, but not simultaneously. Therefore, this term is qualified by one of the following suffixes: S/O for send only; R/O for receive only; S/R for send or receive. Abbreviated hdx.

half-duplex operation—A duplex telegraph system capable of operating in either direction, but not in both simultaneously.

half-duplex repeater—A duplex telegraph repeater provided with interlocking arrangements which restrict the transmission of signals to one direction at a time.

half life—The time interval used to measure the rate of decay of radioactive material. In the first half-life, the amount of radioactive material left unchanged is one-half the original amount; in the next half-life interval, half of the remaining amount, or one-fourth of the original amount remains. Thus, by determining the remaining radioactivity of a fossil and comparing it with the half-life of the material, scientists can estimate the age of the fossil. The half-life of various materials varies greatly—from millionths of a second to billions of years.



Half-wave rectifier.

half-nut—A feed nut which engages half the circumference or less of a lead screw, so that it can be withdrawn from the lead screw to stop the lateral scanning movement.

half-power point—On an amplitude response characteristic or other curve of the magnitude of a network quantity versus frequency, distance, angle, or other variable, the point that corresponds to half the power of a neighboring point having maximum power.

half-power width of a radiation lobe—In a plane containing the direction of the maximum of the lobe, the full angle between the two directions in that plane in which the radiation intensity is one half the maximum value of the lobe.

half-shift register—A logic circuit that consists of a gated input storage element with or without an inverter.

half step—*See* Semitone.

half tap—A bridge that can be placed across conductors without disturbing their continuity.

half-time emitter—A device that produces synchronous pulses midway between the row pulses of a punched card.

half-tone characteristic—In facsimile, the fidelity of the recorded density shadings in comparison with the original transmitted subject copy. Also used to express the relationship between the facsimile signal and the subject or recorded copy.

half-track recorder—*See* Dual-Track Recorder.

half-track tape—Also called two-track tape. Quarter-inch magnetic tape on which half the width of the tape is used for one sound path. Such a tape provides stereo in one direction of tape travel, or monosound in both directions.

half wave—A wave with an electrical length of half a wavelength.

half-wave antenna—An antenna having an electrical length equal to half the wavelength of the signal being transmitted or received.

half-wave dipole—A straight, ungrounded antenna measuring substantially one-half wavelength.

half-wave rectification—The production of a pulsating direct current by passing only half the input cycle of an alternating current. The other half is blocked by the rectifier.

half-wave rectifier—A rectifier utilizing only one half of each cycle to change alternating current into pulsating direct current.

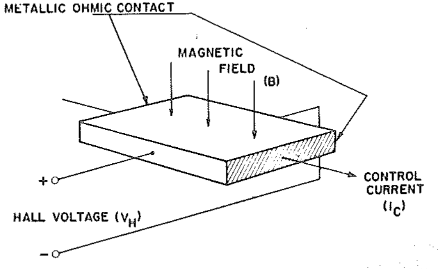
half-wave transmission line—A piece of transmission line having an electrical length equal to half the wavelength of the signal being transmitted or received.

half-wave vibrator—A vibrator used mainly in battery-operated mobile power supplies. It has only one pair of contacts, and supplies an intermittent unidirectional current at its output (usually connected to a half-wave rectifier).

Hall constant—The constant of proportionality in the equation for a current-carrying conductor in a magnetic field. The constant is equal to the transverse electric field (Hall field) divided by the product of the current density and the magnetic field strength. The sign of the majority carrier can be inferred from the sign of the Hall constant.

Hall effect—When a metal strip is placed with its plane perpendicular to a magnetic field and an electric current flows longitudinally through the strip, a potential difference is developed across the strip at right angles to the current flow and to the magnetic field.

Hall generator—A thin wafer of semiconductor material used for measuring a-c power and magnetic field strength. Its output volt-



Hall generator.

age is proportional to the current passing through it times the magnetic field perpendicular to it.

Hall mobility—The product of conductivity and the Hall constant for a conductor or semiconductor. It is a measure of the mobility of the electrons or holes in a semiconductor.

halo—The undesirable ring of light around a spot on the fluorescent screen of a cathode-ray tube.

halogen — A general name applied to four chemical elements, flourine, chlorine, bromine, and iodine, that have similar chemical properties.

halogen quenching—A method of quenching the discharge in a counter tube by the introduction of a small quantity of one of the halogens.

ham — Also called amateur. Slang for a licensed radio operator who operates a station as a hobby rather than a business.

Hamming code—One of the error correction code systems used in data transmission.

hand capacitance—The capacitance introduced when one's hand is brought near a tuning capacitor or other insufficiently shielded part of a receiver.

Handie-Talkie—Trade name of the Motorola Communications Div. for a two-way radio small enough to be carried in one's hand.

hand receiver—An earphone held to the ear by hand.

hand reset—A relay in which the contacts must be reset manually to their original positions after normal conditions are resumed.

handset—A telephone-type receiver and transmitter mounted on a single frame.

handset telephone—*See* Hand Telephone Set.

hand telephone set—Also called a handset telephone. A telephone set having a handset and a mounting which supports the handset when not in use.

hangover—Also called tailing. The smeared or blurred bass notes reproduced by a poorly damped speaker or one mounted in an improperly vented enclosure.

hangup — A condition in which the central processor of a computer is trying to perform an illegal or forbidden operation or in which it is continually repeating the same routine.

hard copy—Typewritten or printed characters on paper produced by a computer at the same time information is copied or converted into machine language that is not easily read by a human.

hard-drawn copper wire—Copper wire that is not annealed after work hardening during drawing, thus providing increased tensile strength.

hard firing—A condition in which the gate signal of an scr is several times the d-c triggering current and in which the rise time of the gate current is short relative to the turn-on time.

hardline—The intelligence link between two objects, consisting of a wire or wires, as opposed to a radio or radar link.

hard magnetic materials—Magnetic materials that are not easily demagnetized.

hardness—Referring to X rays, the quality which determines their penetrating ability. The shorter the wavelength, the harder and hence more penetrating they are.

hardness tester—Equipment for determining the force required to penetrate the surface of a solid.

hard rubber — A material formerly widely used for insulation. It is formed by vulcanizing rubber at high temperature and pressure to give it the desired hardness.

hard solder—Solder composed principally of copper and zinc. It must be red-hot before it will melt. Hard soldering is practically equivalent to brazing.

hard tube—A high-vacuum electronic tube.

hardware—1. Slang for the individual components in a circuit. 2. Particular circuits or functions built into a system.

hard X-rays—Highly penetrating X-rays as distinguished from less penetrating, or soft, X-rays.

harmful interference—Any radiation or any induction which disrupts the proper functioning of an electromagnetic system.

harmonic—A sinusoidal wave having a frequency that is an integral multiple of the fundamental frequency. For example, a wave with twice the frequency of the fundamental is called the second harmonic.

harmonic analysis—1. A method of identifying and evaluating the harmonics that make up a complex waveform of voltage, current, or some other varying quantity. 2. The expression of a given function as a series of sine and cosine terms that are approximately equal to the given function, such as a Fourier series.

harmonic analyzer—Also called harmonic-wave analyzer. A mechanical or electronic device for measuring the amplitude and phase of the various harmonic components of a wave from its graph.

harmonic antenna—An antenna the electrical length of which is an integral multiple of a half wavelength.

harmonic attenuation—Elimination of a harmonic frequency by using a pi network and tuning its shunt resistances to zero for the frequency to be eliminated.

harmonic component—Of a periodic quantity, any one of the simple sinusoidal quantities of the Fourier series into which the periodic quantity may be resolved.

harmonic content—1. The degree of distortion in the output signal of an amplifier. 2. The components remaining after the fundamental frequency has been removed from a complex wave.

harmonic conversion transducer—A conversion transducer in which the useful output frequency is a multiple or submultiple of the input frequency.

harmonic detector—A voltmeter circuit that measures only a particular harmonic of the fundamental frequency.

harmonic distortion—1. The production of harmonic frequencies at the output by the nonlinearity of a transducer when a sinusoidal voltage is applied to the input. The amplitude of the distortion is usually a function of the amplitude of the input signal. 2. A condition that exists in the output of an amplifying circuit when harmonics, added during the process, alter the signal waveform.

harmonic filter—A combination of inductance and capacitance tuned to an undesired harmonic to suppress it.

harmonic generator—A vacuum tube or other generator operated so that it generates strong harmonics in the output.

harmonic interference—Interference between radio stations because harmonics of the carrier frequency are present in the output of one or more stations.

harmonic-leakage power (TR and Pre-TR tubes) — The total radio-frequency power transmitted, through the fired tube in its mount, at other than the fundamental frequencies generated by the transmitter.

harmonic motion—Back and forth motion, such as that of a pendulum, in which the distance on one side of equilibrium always equals the distance on the other side; the acceleration is toward the point of equilibrium and directly proportional to the distance from it. Graphically, harmonic motion is represented by a sine wave.

harmonic producer — A tuning-fork-controlled oscillator used to provide carrier frequencies for broad-band carrier systems. It is capable of producing odd and even harmonics of the fundamental tuning-fork frequency.

harmonic ringing—A system of selectively signaling several parties on a subscriber's line. The different rings are produced by currents which are harmonics of several fundamental frequencies.

harmonic series of sounds — A series in which each basic frequency in it is an integral multiple of a fundamental frequency.

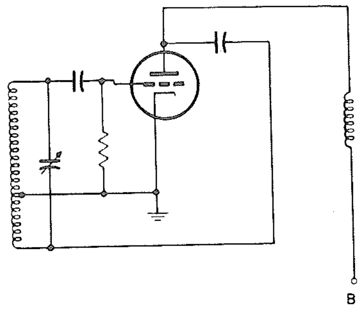
harmonic telephone ringer—A ringer which responds only to alternating current within a very narrow frequency band. A number of such ringers, each responding to a different frequency, are used in one type of selective ringing.

harmonic-wave analyzer — *See* Harmonic Analyzer.

harness—Wires and cables arranged and tied together so they can be connected or disconnected as a unit.

hartley—In computers, a unit of information content equal to one decimal decision, or the designation of one of ten possible and equally likely values or states of anything used to store or convey information. One hartley equals $\log_2 10$ (3.323) bits.

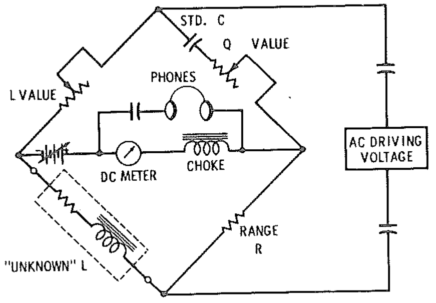
Hartley oscillator—An oscillator in which a parallel-tuned tank circuit is connected between the grid and plate of an electron tube or between the base and collector of a junction transistor, the inductive element of the tank having an intermediate tap at the cathode or emitter potential.



Hartley oscillator.

hash—1. Electrical noise generated within a receiver by a vibrator or a mercury-vapor rectifier. (*Also see* Grass, Garbage.) 2. A completely random interfering signal usually caused by arcing and occasionally by natural environmental disturbances.

hash total—In a computer, a total for checking purposes. It is determined by adding all the digits or all the numbers in a particular field in a batch of unit records, with no attention paid to the meaning or significance of the total.



Hay bridge.

Hay bridge—A four-arm, alternating-current bridge used for measuring inductance in terms of capacitance, resistance, and frequency. The arms adjacent to the unknown impedance are nonreactive resistors, and the opposite arm is comprised of a capacitor in series with a resistor (unlike the Maxwell bridge, where it is in parallel). Usually the bridge is balanced by adjustment of the resistor, which is also in series with the capacitor and one of the nonreactive arms. The balance depends upon the frequency.

hazard—*See* Failure Rate.

Hazeltine neutralizing circuit — An early form of neutralized radio-frequency amplifier circuit.

H-bend—Also called H-plane bend. In waveguide technique, a smooth change in the direction of the axis of the waveguide. Throughout the change, the axis remains perpendicular to the direction of polarization.

H-display—Also called H-scan. In radar, a B-display modified to indicate the angle of elevation. The target appears as two closely spaced blips which approximate a short, bright line that slopes in proportion to the sine of the angle of target elevation.

head—A device which reads, records, or erases information in a storage medium; e.g., a small electromagnet used to read, write, or erase information on a magnetic drum or tape.

head alignment — Positioning the record-playback head on a tape recorder so that its gap is perpendicular to the tape.

head amplifier—An audio-frequency amplifier mounted on or near the sound head of a motion-picture projector to amplify the extremely weak output of the phototube.

head demagnetizer—Device for eliminating any magnetism built up in a recording head.

header—1. The part of a sealed component or assembly that provides support and insulation for the leads passing through the walls. 2. A preformed part made of an insulating material and containing the input and output leads of a module or component. May be part of, or attached to, the case by an adhesive bond or embedment material. Forms a portion of the other case of the module or component.

head guy—A messenger cable and attachments placed so they pull toward the pole line.

heading—The direction of a ship, aircraft, or other object with reference to true, magnetic, compass, or grid north.

headlight—An aircraft radar antenna small enough to be housed in the wing, like an automobile headlight. The beam operates like a searchlight.

headphone—Also called a head receiver or phone. A device held against the ear and having a diaphragm which vibrates according to current variations. It reproduces the incoming electrical signals as sound. Thus, the headphone permits private listening to a receiver, amplifier, or other device.

head receiver—*See* Headphone.

headset—A headphone (or a pair of headphones) and its associated headband and connecting cord.

head stack—A group of two or more heads mounted in a single unit, used to provide multiple-track recording or reproduction.

head-to-tape contact—The degree to which the surface of the magnetic coating approaches the surface of the record or replay heads during normal operation of a recorder. Good head-to-tape contact minimizes separation loss and is essential in obtaining high resolution.

hearing aid—A small audio reproducing system for the hard of hearing. It consists of a microphone, amplifier, battery, and earphone and is used to increase the sound level normally received by the ear.

hearing loss—Also called deafness. The hearing loss of an ear at a specified frequency—i.e., the ratio, expressed in decibels, of its threshold of audibility to the normal threshold.

hearing loss for speech—The difference in decibels between the speech levels at which the average normal ear and the defective ear, respectively, reach the same intelligibility. It is often arbitrarily set at 50%.

heat aging—A test used to indicate the relative resistance of various insulating materials to heat degradation.

heat coil—A protective device that grounds or opens a circuit, or both, when the current rises above a predetermined value. A mechanical element moves when the fusible substance that holds it in place is heated above a certain point by current through the circuit.

heater—1. Also called filament. An element that supplies the heat to an indirectly heated cathode. 2. A resistor that converts electrical energy into heat.

heater biasing—Application of a d-c potential to the heater to eliminate diode conduction between it and some other element within the tube.

heater current—The current flowing through a heater in a vacuum tube.

heater voltage—The voltage between the terminals of a heater.

heater-voltage coefficient—In a klystron, the frequency change per volt of heater voltage change when the reflector voltage is adjusted for the peak of a reflector voltage mode.

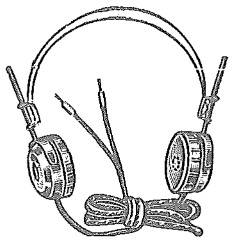
heat-eye tube—A cathode-ray tube powered by a midget generator. It is used as an infrared instrument that can "see" in the dark.

heat gradient—The difference in temperature between two parts of the same object.

heating effect of a current—Assuming a constant resistance, the amount of heat produced by the current through it. It is proportionate to the square of the current.

heating element—The wirewound resistor, terminals, and insulating supports used in electric cooking and heating devices.

heating pattern—In induction or dielectric heating, the distribution of temperature in a load or charge.



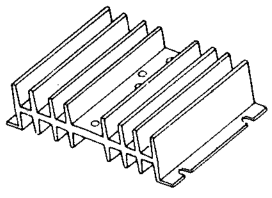
Headset.

heating station—In induction or dielectric heating, the work coil or applicator and its associated production equipment.

heat loss—The loss due to conversion of part of the electric energy into heat.

heat of emission—Additional heat energy that must be supplied to an electron-emitting surface to keep its temperature constant.

heat of radioactivity—Heat generated by radioactive disintegration.



Heat sink.

heat sink — Any device that absorbs and draws off heat from a hot object, reradiating it into the surrounding atmosphere.

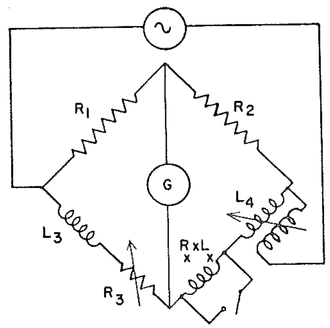
heat waves—Infrared radiation similar to radiowaves but of a higher frequency.

heat writer—A direct writer which records on thermally sensitive paper with a heated stylus.

Heaviside - Campbell mutual - inductance bridge — A Heaviside mutual - inductance bridge in which one inductive arm contains a separate inductor that is included in the bridge arm during the first of a pair of measurements and is short-circuited during the second. The balance is independent of frequency. (*Also see* Heaviside Mutual-Inductance Bridge.)

Heaviside layer—Also called the Kennelly-Heaviside layer. The region of the ionosphere that reflects radio waves back to earth.

Heaviside mutual-inductance bridge—An alternating-current bridge normally used for the comparison of self- and mutual-inductances. Each of the two adjacent arms contains self-inductance, and one or both of them have mutual inductance to the supply circuit. The other two arms normally are nonreactive resistors. The balance is independent of frequency.



Heaviside-Campbell mutual-inductance bridge.

heavy hydrogen—Another term for deuterium (H^2) or tritium (H^3).

hecto—A prefix meaning 100.

hectometric wave—An electromagnetic wave between the wavelength limits of 100 and 1000 meters corresponding to the frequency range 3 MHz to 300 MHz.

heelpiece—Part of a relay magnetic structure at the end of a coil, opposite the armature. It generally supports the armature and completes the magnetic path between it and the core of the coil.

Hefner lamp—A standard source that gives a luminous intensity of 0.9 candlepower.

height control—In a television receiver, the adjustment which determines the amplitude of the vertical-scanning pulses and hence the height of the picture.

height finder—A radar which measures the altitude of an airborne object.

height-position indicator—A radar display which simultaneously shows the angular-elevation slant range and height of objects.

height-range indicator—A cathode-ray tube from which altitude and range measurements of airborne objects may be viewed.

Heising modulation—*See* Constant-Current Modulation.

helical—Spiral-shaped.

helical antenna—Also called a helical-beam antenna. A spiral conductor wound around a circular or polygonal cross section. The axis of the spiral normally is mounted parallel to the ground and fed at the adjacent end. The radiation produced has approximately a circular polarization and is confined mainly to a single lobe located along the axis of the spiral.

helical-beam antenna—*See* Helical Antenna.

helical potentiometer—A precision potentiometer which requires several turns of the control knob to move the contact arm from one end of the spiral-wound resistance element to the other end.

helical scanning — 1. Radar scanning in which the r-f beam describes a distorted spiral motion. The antenna rotates about the vertical axis while the elevation angle rises slowly from zero to 90°. 2. Method of facsimile scanning in which the elemental area sweeps across the copy in a spiral motion.

helionics—The conversion of solar heat to electric energy.

helix—A spiral.

helix recorder—A recorder in which helical scanning is used.

Helmholtz coil — A phase - shifting network used for determining the range in certain types of radar equipment. It consists of fixed and movable coils. The phase is kept constant at the input, but may be continually shifted from 0° to 360° at the output.

Helmholtz resonator—An acoustic enclosure with a small opening which causes the enclosure to resonate. The frequency at which it does depends on the geometry of the resonator.

hemimorphic—Terminated at the two ends by dissimilar sets of faces.

HEM wave—*See* Hybrid Electromagnetic Wave.

henry—Abbreviated h. The measure of inductance. In a closed circuit one henry of inductance is present, when a current variation of 1 ampere per second induces 1 volt.

heptode—A seven-electrode electron tube containing an anode, a cathode, a control electrode, and four grids.

hermaphroditic connector—A connector in which both mating contacts are exactly alike at their mating face.

hermetically sealed relay—A relay in a gas-tight enclosure which has been completely sealed by fusion or comparable means to ensure a low rate of gas leakage over a long period of time.

hermetic sealing—The evacuating and sealing of an enclosure to make it airtight.

herringbone pattern—Television interference seen as one or more horizontal bands of closely spaced V- or S-shaped lines.

hertz—Abbreviated Hz. A unit of frequency equal to one cycle per second.

Hertz antenna—An antenna system which does not depend for its operation on the presence of ground. Its resonant frequency is determined by its distributed capacitance, which varies according to its physical length.

Hertz effect—The ionization and spark discharge produced by ultraviolet radiation.

Hertzian oscillator—A type of oscillator for producing ultrahigh-frequency oscillations. It consists of two metal plates or other conductors separated by an air gap. The capacitor formed has such a small capacitance that ultrahigh-frequency oscillations can occur.

Hertzian waves—Electromagnetic waves of frequencies between 10 kHz and 30,000 GHz. A radio wave.

Hertz vector—A vector which specifies the electromagnetic field of a radio wave. Both the electric and the magnetic intensities can be specified in terms of it.

heterodyne—Also called beat. To mix two frequencies together in order to produce two other frequencies equal to the sum and difference of the first two. For example, heterodyning a 100-kHz and a 10-kHz signal will produce a 110-kHz (sum frequency) and a 90-kHz (difference frequency) signal.

heterodyne conversion transducer (converter)—A conversion transducer in which the output frequency is the sum or difference of the input frequency and an integral multiple of the frequency of another wave.

heterodyne detection—Detection (or conversion) by mixing two signals together to generate the intermediate frequency in a superheterodyne receiver or to make c-w signals audible.

heterodyne detector—A detector that converts an incoming r-f signal to an audible tone by heterodyning. It incorporates a local oscillator (called a beat-frequency oscillator).

heterodyne frequency—The sum or difference frequency produced by combining two other frequencies.

heterodyne frequency meter—*See* Heterodyne Wavemeter.

heterodyne oscillator—An oscillator which produces a desired frequency by combining two other frequencies (e.g., two radio frequencies to produce an audio frequency, or the incoming and local-oscillator frequencies to produce the intermediate frequency of a superheterodyne receiver).

heterodyne principle—*See* Heterodyne.

heterodyne reception—Also called beat reception. Reception by combining a received high-frequency wave with a locally generated wave in a nonlinear device to produce sum and difference frequencies at the output.

heterodyne-type frequency meter—An instrument for measuring frequency by producing a zero difference frequency (zero beat) between the signal under test and an internally generated signal.

heterodyne wavemeter—A wavemeter employing the heterodyne principle to compare the frequency being measured with a frequency being generated in a calibrated oscillator circuit.

heterodyne whistle—A steady squeal heard in a radio receiver when the signals from stations having nearly equal frequencies beat together.

heterodyning—*See* Heterodyne.

heterogeneity—A state or condition being unlike in nature, kind, or degree.

heterogeneous—Composed of different materials (opposite of homogeneous).

heterosphere—The portion of the upper atmosphere in which the relative proportions of oxygen, nitrogen, and other gases are unfixed and radiation particles and micrometeroids are mixed with the air particles.

heuristic program—A set of computer instructions that simulate the behavior of human operators in approaching similar problems.

hexadecimal number system—A number system having as its base the equivalent of the decimal number sixteen.

hexode—A six-electrode electron tube containing an anode, a cathode, a control electrode, and three grids.

hf—Abbreviation for high frequency.

HH beacon—A nondirectional radio homing beacon with a power output of 2,000 watts or more.

hierarchy—A series of items classified according to rank or order.

hi-fi—*See* High Fidelity.

high band—Television channels 7 - 13, covering a frequency range of 174-216 MHz.

high boost—*See* High-Frequency Compensation.

high-contrast image—A picture in which strong contrast between light and dark areas is visible. Intermediate values, however, may be missing.

high definition—Television or facsimile equivalent of high fidelity.

high-energy materials—Also called hard magnetic materials. Magnetic materials having a comparatively high energy product, e.g., materials used for permanent-magnets.

highest probable frequency—Abbreviated HPF. An arbitrarily chosen frequency value 15% above the F_2-layer MUF (maximum usable frequency) for the radio circuit. For the E-layer, the HPF is equal to the MUF.

high fidelity—Popularly called hi-fi. The characteristic which enables a system to reproduce sound as nearly like the original as possible.

high-fidelity receiver—A radio receiver capable of receiving and reproducing, without noticeable distortion, the original modulation impressed on the carrier waves.

high filter—An audio circuit designed to remove undesired high-frequency noise from the program material. Such noise includes record scratch, tape hiss, a-m whistles, etc.

high frequency—Abbreviated hf. The frequency band from 3 to 30 MHz (10 meters to 100 meters).

high-frequency alternator—An alternator capable of generating radio-frequency carrier waves.

high-frequency band—The band of frequencies extending from 3 to 30 MHz.

high-frequency bias—In a tape recorder, a sinusoidal voltage that is mixed with the signal being recorded to better the linearity and dynamic range of the recorded signal. In practice, the bias frequency is three to four times the highest information frequency to be recorded.

high-frequency broadcast station—A commercial station licensed for transmission to the general public and operated in the high-frequency broadcast band, using frequency modulation exclusively.

high-frequency carrier telegraphy—Carrier telegraphy with the carrier currents above the frequencies transmitted over a voice telephone channel.

high-frequency compensation—Also called high boost. An increase in the amplification of the high frequencies with respect to the low and middle frequencies within a given band of frequencies.

high-frequency heating—*See* Electronic Heating.

high-frequency induction heater or furnace—An induction heater or furnace using frequencies much higher than the standard 60-hertz.

high-frequency resistance—Also called r-f or a-c resistance. The total resistance offered by a device in a high-frequency a-c circuit. This includes the d-c and all other resistances due to the effects of the alternating current.

high-frequency treatment—Therapeutic use of intermittent and isolated trains of heavily damped oscillations having a high frequency and voltage and a relatively low current.

high-frequency trimmer—A trimmer capacitor that is used to calibrate the high-frequency end of the tuning range in a superheterodyne receiver.

high-frequency unit—*See* Tweeter.

high-frequency welding—*See* Radio-Frequency Welding.

high-level detector—A linear power detector with a voltage-current characteristic that may be treated as a straight line or two intersecting lines.

high-level firing time—The time required to establish a radio-frequency discharge in a switching tube after radio-frequency power is applied.

high-level modulation—A system in which the modulation is introduced at a point where the power level approximates the output power.

high-level, radio-frequency signal (TR, ATR, and pre-TR tubes)—A radio-frequency signal with sufficient power to fire the tube.

high-level vswr (switching tubes)—The voltage standing-wave ratio due to a fired tube in its mount, located between a generator and the matched termination in a wave guide.

highlight—The brightest portion of a reproduced image.

high-mu tube—A vacuum tube with a high amplification factor.

high-pass filter—A wave filter having a single transmission band extending from some critical, or cutoff, frequency other than zero, up to infinite frequency.

high-performance equipment—Equipment having sufficiently exacting characteristics to permit their use in trunk or link circuits.

high-potential test—A test for determining the breakdown point of insulating materials and spacings. It consists of applying a voltage higher than the rated voltage between two points or between two or more windings. However, it is not a test of conductor insulation.

high-power silicon rectifiers—A group of rectifiers with continuous ratings exceeding 50 average amperes per section in a single-phase, half-wave circuit.

high Q—Having a high ratio of reactance to effective resistance. The factor determining the efficiency of a reactive component.

high-rate discharge—The storage-battery discharge equivalent to the heaviest possible duty in service.

high-recombination-rate contact—A semiconductor - to - semiconductor or metal-to-semiconductor contact at which thermal equilibrium charge-carrier concentrations are maintained substantially independent of current density.

high-resistance joint—A faulty union of conductors or conductor and terminal. The result is less current flow and a drop in voltage at the union.

high-resistance voltmeter—A voltmeter having a resistance considerably higher than 1,000 ohms per volt. As a result, it draws very little current from the circuit being measured.

high-speed bus—*See* Memory Register.

high-speed carry—In a computer, a type of carry in which: 1. A carry into a column results in a carry out of that column, because the sum without carry in that column is 9. 2. Instead of a normal adding process, a special process is used which takes the carry at high speed to the actual column where it is added. Also called standing-on-nines carry.

high-speed d-c circuit breaker—A device which starts to reduce the current in the main circuit in 0.01 second or less, after the occurrence of the d-c overcurrent or the excessive rate of current rise.

high-speed relay—A relay designed specifically for short-operate or short-release time, or both.

high-speed telegraph transmission—Transmission of code at higher speeds than are possible with hand-operated keys.

high tension—Lethal voltages, on the order of thousands of volts.

high-tension magneto—A self-contained generator in which the required high potential is generated directly; no induction coil is needed.

high-vacuum phototube—A phototube that is highly evacuated so that its electrical characteristics are essentially unaffected by gaseous ionization. In a gas phototube, some gas is intentionally introduced.

high-vacuum rectifier—A vacuum-tube rectifier in which conduction is entirely by electrons emitted from the cathode.

high-vacuum tube—An electron tube that is highly evacuated so that its electrical characteristics are essentially unaffected by gaseous ionization.

high-velocity scanning—The scanning of a target with electrons of such velocity that the secondary-emission ratio is greater than unity.

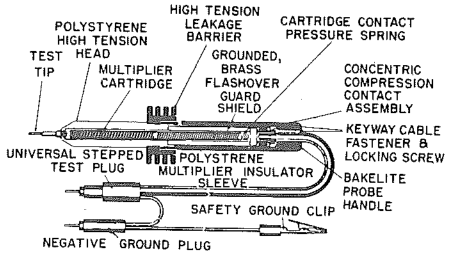
high voltage—The accelerating potential that speeds up the electrons in a beam of a cathode-ray tube.

high-voltage probe—A probe with a high internal resistance, for measuring extremely high voltages. It is used with a voltmeter having an internal resistance of 20,000 ohms per volt or more.

hill-and-dale recording—*See* Vertical Recording.

hinge—A joint in a relay that permits movement of the armature relative to the stationary parts of the relay structure.

hinged-iron ammeter—A moving-iron ammeter in which the fixed portion of the magnetic circuit is placed around the conductor to measure the current through it.



HIGH TENSION LEAKAGE BARRIER
POLYSTYRENE HIGH TENSION HEAD
CARTRIDGE CONTACT PRESSURE SPRING
TEST TIP
MULTIPLIER CARTRIDGE
GROUNDED, BRASS FLASHOVER GUARD SHIELD
CONCENTRIC COMPRESSION CONTACT ASSEMBLY
KEYWAY CABLE FASTENER & LOCKING SCREW
UNIVERSAL STEPPED TEST PLUG
POLYSTRENE MULTIPLIER INSULATOR SLEEVE
BAKELITE PROBE HANDLE
SAFETY GROUND CLIP
NEGATIVE GROUND PLUG

High-voltage probe.

HIPERNAS—Acronym for HIgh PERformance NAvigation System. A self-compensated, pure-inertial guidance system.

hi-pot—1. *See* Dielectric Breakdown Voltage. 2. Contraction of high potential. *Commonly* refers to a device used for testing insulation breakdown or leakage, with high voltages. High potting is the verb.

hiss—Random noise characterized by prolonged sibilant sounds in the audio-frequency range.

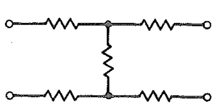
histogram—A graphical representation of a frequency distribution by a series of rectangles which have for one dimension a distance proportional to a definite range of frequencies, and for the other dimension a distance proportional to the number of frequencies appearing within the range.

hit—*See* Flash.

hit-on-the-fly printer—A mechanical printer in which the printing head is in continual motion.

hits—Momentary line disturbances which could result in mutilation of characters being transmitted.

H-lines—Imaginary lines that represent the direction and strength of magnetic flux on a diagram.



H-network.

H-network—A network composed of five impedance branches. Two are connected in series between an input terminal and an output terminal and two are connected between another input terminal and another output terminal. The fifth is connected from the junction points of the two branches.

hog horn—A microwave feed horn shaped so that the input energy from the waveguide approaches from the same direction as the horn opening.

hold—Opposite of clear. 1. To maintain storage elements in charge storage tubes at equilibrium potentials by electron bombardment. 2. In computers, to retain information contained in one storage device after copying it into a second storage device.

hold control—In a television receiver, the adjustment which controls the frequency of the vertical- or horizontal-scanning pulses and hence the stability of the picture.

hold current—Also called the electrical hold value. The minimum current which will keep the contact springs energized in a relay.

hold electrode—In a mercury switch, the electrode that remains in contact with the mercury pool while the circuit is being closed or opened.

holding anode—In a mercury-arc rectifier, a small auxiliary anode that maintains the ionization while the main anode current is zero.

holding beam—A diffused beam of electrons for regenerating the charges retained on the dielectric surface of an electrostatic memory or storage tube.

holding circuit—Also called a locking circuit. An alternate operating circuit which, when completed, maintains sufficient current in a relay winding to keep the relay energized after the initial current has ceased.

holding coil—A separate relay coil which keeps the relay energized after the original current has been removed.

holding current—That value of average forward current (with the gate open) below which a silicon-controlled rectifier returns to the forward blocking state after having been in forward conduction.

holding gun—In a storage tube, the source of electrons constituting the holding beam.

holding time—The total time a trunk or circuit is in use on a call, including both operator's and user's time.

hold mode—In integrators or other charge-storage circuits, a condition or time interval in which input (s) are removed and the circuit is commanded (or expected) to maintain a constant output.

hold-off voltage—The maximum voltage an electronic flash tube will stand without self-flashing. Normal hold-off voltage is reduced at the end of lamp life and in the presence of high temperatures or r-f fields.

hold time—In resistance welding, the time that is allowed for the weld to harden.

hole—In the electronic valence structure of a semiconductor, a mobile vacancy which acts like a positive electronic charge with a positive mass.

hole conduction—Conduction occurring in a semiconductor when electrons move into holes under the influence of an applied voltage and thereby create new holes. The apparent movement of such holes is toward the more negative terminal, and is hence equivalent to a flow of positive charges in that direction.

hole current—Conduction in a semiconductor when electrons move into holes, creating new holes. The holes appear to move toward the negative terminal, giving the equivalent of positive charges flowing to the terminal.

hole density—In a semiconductor, the density of holes in an otherwise full band.

hole injection—The production of mobile vacancies in an N-type semiconductor when a voltage is applied to a sharp metal point in contact with the surface of the material.

hole injector—A pointed metallic device for injecting holes into an N-type semiconductor.

hole-in-the-center effect—Also called hole-in-the-middle effect. The lower volume or absence of sound between the left and right speakers of a stereo system.

hole mobility—The ability of a hole to travel easily through a semiconductor.

hole site—The area on a computer punch card or paper tape where a hole may or may not be punched. It can be a form of binary storage in which a hole represents a 1 and the absence of a hole represents a 0.

hole storage factor (K'_s)—In a transistor, the excess stored charge (when the transistor is in saturation) per unit excess base current. Excess base current is defined as the amount of current supplied to the base in excess of the current required to just keep the transistor in saturation.

hole trap—A semiconductor impurity which can trap holes by releasing electrons into the conduction or valence bands.

Hollerith code—A code based on the punching of holes in cards at specified locations. From one to three punches may be made in each column of the card and up to 80 columns may be punched in each card. Each column corresponds to one character; the specific character is determined by the number and location of the punches in that column.

hollow-cathode tube—A gas discharge tube with a hollow cathode closed at one end. Almost all the radiation is from the cathode glow within the hollow cathode.

hollow core—A plain ferrite core having a center hole for mounting purposes.

home loop—An operation involving only those input and output units associated with the hole terminal.

homing—1. Approaching a desired point by maintaining some indicated navigational parameter constant (other than altitude). 2. In missile guidance, the use of radiation from a target to establish a collision course.

homing adapter—A device used with an aircraft radio receiver to produce aural and/or visual signals which indicate the direction of a transmitting radio station.

homing antenna—A type of directional-antenna array used for pinpointing a target.

homing beacon—A radio transmitter which emits a distinctive signal for determining bearing, course, or location.

homing device—1. An automatic device that moves or rotates in the correct direction without first having to go to the end of its travel in the opposite direction. 2. A radio device that guides an aircraft to an airport or transmitter site.

homing guidance—A missile-guidance system in which the missile steers itself toward a target by means of a self-contained mechanism (infrared detectors, radar, etc.). Activated by some distinguishing characterism of the target. Homing guidance may be active, semiactive, or passive.

homing relay—A stepping relay that returns to a specified starting position prior to each operating cycle.

homing station—A radionavigational aid incorporating direction-finding facilities.

homodyne reception—Also called zero-beat reception. A system of reception using a locally generated voltage at the carrier frequency.

homogeneity—The state or condition of being similar in nature, kind, or degree.

homogeneous—Of the same nature (the opposite of heterogeneous).

homologous field—A field in which the lines of force in a given plane all pass through one point (e.g., the electric field between two coaxial charged cylinders).

homopolar — Electrically symmetrical — i.e., having equally distributed charges.

homopolar generator—A d-c generator in which all the poles presented to the armature are of the same polarity, so that the armature conductor always cuts the magnetic lines of force in the same direction. A pure direct current can thus be produced without commutation.

homopolar magnet—A magnet with concentric pole pieces.

homosphere—That part of the atmosphere which is made up mostly of atoms and molecules found near the earth's surface, and retaining the same relative proportions of oxygen, nitrogen, and other gases throughout.

homotaxial—A term coined by RCA from "homogeneous" and "axial" to describe a single-diffused transistor with a base region of homogeneous resistivity silicon in the axial direction (emitter-to-collector).

honeycomb coil—Also called duolateral or lattice-wound coil. A coil with the turns wound crisscross to reduce the distributed capacitance.

hood—A shield placed over a cathode-ray tube to eliminate extraneous light and thus make the image on the screen appear more clearly.

hookswitch — A hook or plunger-operated switch used in a telephone set to open the circuit when the instrument is not in use.

hook transistor — A transistor having four alternating P-type and N-type layers, with one layer floating between the base layer and the collector layer. This arrangement gives high emitter-input current gains. The PNPN transistor has a P-type floating layer, while an NPNP transistor has an N-type floating layer.

hookup—1. Method of connection between

the various units in a circuit. 2. The diagram of connections used.

hookup wire—The wire used in coupling circuits together. It may be solid or stranded, and is usually tinned and insulated No. 18 or 20 soft-drawn copper.

hop—An excursion of a radio wave from the earth to the ionosphere and back. It is usually expressed as single-, double-, and multihop. The number of hops is called the order of reflection.

hopoff—In a potentiometer, the sudden jump in resistance as the contact is rotated over the junction of two resistance slopes or over the junction of two resistance slopes or over resistance slope. The magnitude of the hopoff is dependent on the ratio of the slopes and on the junction blending characteristic.

horizon—An apparent or visible junction of earth and sky as seen on or above the earth. It bounds the part of the earth's surface that can be reached by the direct wave of a radio station. The distance to the horizon is affected by atmospheric refraction.

horizon distance—The space between the farthest visible point and the transmitter antenna. It is the distance over which ultra-high-frequency transmission can be received under ordinary conditions with an unelevated receiving antenna.

horizontal—1. Perpendicular to the direction of gravity. 2. In the direction of or parallel to the horizon. 3. On a level.

horizontal axes—The three horizontal axes of crystallographic reference.

horizontal blanking—Cutting off the electron beam between successive active horizontal lines during retrace.

horizontal blanking pulse—A rectangular pedestal in the composite television signal. It occurs between active horizontal lines and cuts off the beam current of the picture tube during retrace.

horizontal centering control—In a television receiver or cathode-ray oscilloscope, the adjustment for moving the entire display back and forth.

horizontal-convergence control—In a color television receiver, the control which adjusts the amplitude of the horizontal dynamic convergence voltage.

horizontal-deflecting electrode—A pair of electrodes that move the electron beam from side to side on the screen of a cathode-ray tube employing electrostatic deflection.

horizontal-discharge tube—A vacuum tube used in the horizontal-deflection circuit to discharge a capacitor and thereby form the sawtooth scanning wave. (*Also see* Discharge Tube.)

horizontal-drive control—In an electromagnetically deflected television receiver, the control which adjusts the ratio of the pulse amplitude to the linear portion of the scanning-current wave.

horizontal dynamic convergence—Convergence of the three electron beams in a color

picture tube at the aperture mask during scanning of a horizontal line.

horizontal frequency—*See* Line Frequency.

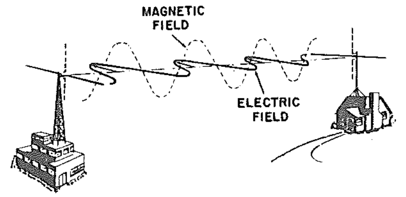
horizontal hold control—A synchronization control which varies the free-running frequency of the horizontal deflection oscillator so it will be in step with the scanning frequency at the transmitter.

horizontal hum bars — Broad, horizontal, moving or stationary bars, alternately dark and light, that extend over an entire television picture. They are caused by interference at approximately 60 Hz or a harmonic of 60 Hz.

horizontal-linearity control—In a television receiver, the control for adjusting the width at the left side of the screen.

horizontal line frequency—*See* Line Frequency.

horizontal lock—The circuit that maintains horizontal synchronization in a television receiver.



Horizontally polarized wave.

horizontally polarized wave — A linearly polarized wave with a horizontal electric-field vector.

horizontal-output transformer—*See* Flyback Transformer.

horizontal parabola control—*See* Phase Control.

horizontal polarization — Transmission in which the electrostatic field leaves the antenna in a horizontal plane. Elements of the transmitting and receiving antennas likewise are horizontal. Horizontal polarization is standard for television in the United States.

horizontal repetition rate—Also called horizontal scanning frequency. The number of horizontal lines per second (15,750 hertz in the United States).

horizontal resolution—The number of picture elements in a horizontal scanning line that can be distinguished.

horizontal retrace—The line that would be seen on the screen, while the spot is returning from right to left, if retrace blanking were not used.

horizontal ring-induction furnace—A furnace for melting metal. It comprises an open trough or melting channel, a primary inductor winding, and a magnetic core which links the melting channel to the primary winding.

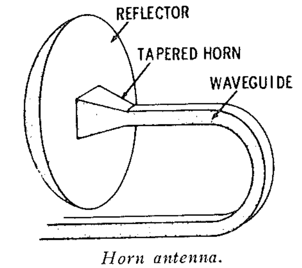
horizontal-scanning frequency—*See* Horizontal-Repetition Rate.

horizontal sweep—Movement of the electron beam from left to right across the screen or the scene being televised.

horizontal-sync discriminator — A circuit employed in the flywheel method of synchronization to compare the phase of the horizontal-sync pulses with that of the horizontal-scanning oscillator.

horizontal-sync pulse — The rectangular pulses which occur above the pedestal level between each active horizontal line. They keep the horizontal scanning at the receiver in step with the horizontal scanning at the transmitter.

horn—Also called an acoustic horn. A tubular or rectangular enclosure for radiating or receiving acoustic waves. (*Also see* Horn Antenna.)



Horn antenna.

horn antenna—Also called a horn. A tubular or rectangular microwave antenna which is wider at the open end and through which radio waves are radiated into space.

horn arrester—A lightning arrester that has a spark gap with upward-projecting diversion horns of thick wire. When the arc is formed, it travels up the gap, and is extinguished upon reaching the widest part of the gap.

horn cutoff frequency—A frequency below which an exponential horn will not function correctly, because it fails to provide for proper expansion of the sound waves.

horn loading — A method of coupling a speaker diaphragm to the listening space by an expanding air column having a small throat and large mouth.

horn mouth—The wide end of a horn.

horn radiator—An open-ended, metallic device for concentrating energy from a waveguide and directing this energy into space.

horn speaker—A speaker in which a horn couples the radiating element to the medium.

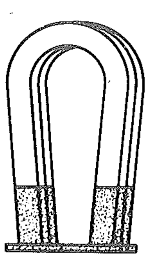
horn throat—The narrow end of a horn.

horsepower — Abbreviated hp. A unit of power, or the capacity of a mechanism to do work. It is the equivalent of raising 33,000 pounds one foot in one minute, or 550 pounds one foot in one second. One horsepower equals 746 watts.

horseshoe magnet—A permanent magnet or electromagnet shaped like a horseshoe or U to bring the two poles close together.

hot—1. Connected, alive, energized; pertains to a terminal or any ungrounded conductor. 2. Not grounded.

hot-carrier diode — A semiconductor diode



Horseshoe magnet.

which uses the thermoelectric effect of radio-frequency heating in bulk semiconductor material to provide current carriers. Characterized by relatively high power and low internal noise generation.

hot carriers—In barrier diodes, carriers that have energies greater than those that are in thermal equilibrium with the metal. Thus, electrons that cross the junction from semiconductor to metal must be energetic enough to surmount the barrier. Therefore electrons that are energetic enough to cross the junction are called "hot electrons."

hot cathode—Also called thermionic cathode. A cathode which supplies electrons by thermionic emission. (As opposed to a cold cathode, which has no heater.)

hot-cathode tube—Also called thermionic tube. Any electron tube containing a hot cathode.

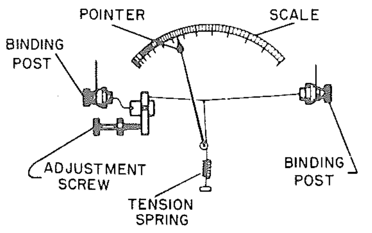
hot-cathode X-ray tube—A high-vacuum X-ray tube in which a hot rather than cold cathode is used.

hot electrons—*See* Hot Carriers.

hot spot—The point of maximum temperature on the outside of a device or component.

hot tin dip—A process of passing a bare wire through a bath of molten tin to provide a coating.

hot-wire ammeter—Also called thermal ammeter. An ammeter in which the expansion of a wire moves a pointer to indicate the amount of current being measured. The current flows through the wire and changes its length in proportion to I^2. Instability because of wire stretching, and the lack of ambient temperature compensation make the hot-wire ammeter commercially unsatisfactory.



Hot-wire ammeter.

hot-wire anemometer—An instrument that measures the velocity of wind or a gas by its cooling effect on an electrically heated wire.

hot-wire instrument—An electrothermic instrument operated by expansion of a wire heated by the current it is carrying.

hot-wire microphone—A microphone in which the cooling or heating effect of a sound wave changes the resistance of a hot wire and thus the current through it.

hot-wire relay—A form of linear-expansion time-delay relay in which the longitudinal expansion of a wire, when heated, provides the mechanical motion to open or close contacts. The time required to heat the wire constitutes the delay.

hot-wire transducer—A unilateral transducer in which the cooling or heating effect of a sound wave changes the resistance of a hot wire and thus the current.

housekeeping—In a computer routine, those operations, such as setting up constants and variables for use in the program, that contribute directly ot the proper operation of the computer but not to the solution of the problem.

howl—An undesirable prolonged wail produced in a speaker by electric or acoustic feedback.

howler—An electromechanical device which produces an audio-frequency tone.

hp—Abbreviation for horsepower.

H-pad—An attenuation network in which the elements are arranged in the form of the letter *H*.

h-parameters—*See* Hybrid Parameters.

h-particle—The positive hydrogen ion or proton resulting from bombardment of the hydrogen atom by alpha rays or fast-moving positive ions.

HPF—Abbreviation for highest probable frequency.

H plane—The plane in which the magnetic field of an antenna lies. It is perpendicular to the E plane. The principal H plane of an antenna is the H plane that also contains the direction of maximum radiation.

H-plane bend—*See* H-Bend.

H-plane T-junction—Also called shunt T-junction. A waveguide T-junction in which the structure changes in the plane of the magnetic field.

H-scan—*See* H-Display.

hub—On a control panel or plugboard, a socket or receptacle into which an electrical lead or plug wire may be connected for the purpose of carrying signals.

hue—Often used synonymously with the term "color," but does not include gray. It is the dominant wavelength—i.e., the one which distinguishes a color as red, yellow, etc. Varying saturations may have the same hue.

hue control—On a color television receiver, the operating control that changes the hue (color) of the picture.

hull potential—The voltage difference between a reference electrode and an immersed metallic hull, or the bonded underwater metallic appendages of a nonmetallic hull.

hum—In audio-frequency systems, a low-pitched droning noise consisting of several harmonically related frequencies. It results from an alternating-current power supply, ripple from a direct-current power supply, or induction from exposure to a power system. By extension, the term is applied in visual systems to interference from similar sources.

human engineering—The science and art of developing machines for human use, giving consideration to the abilities, limitations, habits, and preferences of the human operator.

hum-balancing pot—A potentiometer usually placed across the heater circuit. Its arm is grounded so that the heater voltage is balanced with respect to ground.

hum bar—A dark band extending across the picture. It is caused by excessive 60-hertz hum (or harmonics) in the signal applied to the picture-tube input.

hum bucking—The introduction of a small amount of voltage, at the power-line frequency, into a circuit to cancel unwanted power.

hum-bucking coil—A coil wound around the field coil of a dynamic speaker and connected in series opposition with the voice coil. In this way, any hum voltage induced in the field coil will be induced in the voice coil in the opposite direction and buck, or cancel, the effects of the hum.

humidity transducer—A layer of hygroscopic (moisture-absorbing) substance deposited between two metal electrodes. These electrodes establish electrical contact with the hygroscopic chemical, which serves as a resistance element. Since the chemical coating tends to absorb moisture from the surrounding air, its resistance decreases as the humidity increases. In this manner, humidity variations are converted to resistance variations.

humming—A sound produced by transformers having loose laminations or by magnetostriction effects in iron cores. The frequency of the sound is twice the power-line frequency.

hum modulation—Modulation of a radio-frequency or detected signal by using hum.

hunting—An undesirable oscillation of an automatic control system where the controlled variable swings on both sides of the predetermined reference value without settling on it.

hv or HV—Abbreviation for high voltage.

H-vector—A vector which represents the magnetic field of an electromagnetic wave. In free space, it is perpendicular to the E-vector and the direction of propagation.

H-wave—A mode in which electromagnetic energy can be transmitted in a waveguide. An H-wave has an electric field perpendicular to the length of the waveguide, and a magnetic field parallel as well as perpendicular to the length.

hybrid—*See* Hybrid Junction.

hybrid balance—A measure of the degree of balance between two impedances connected to two conjugate sides of a hybrid set. It is given by the formula for return loss.

hybrid circuit—1. A circuit which combines the thin-film and semiconductor technologies. Generally, the passive components are made by thin-film techniques, and the active components by semiconductor techniques. The active devices are attached to the thin-film passive components by a suitable bonding process. 2. Also called two-wire–four-wire terminating set. In telephone transmission circuits, a circuit for interconnecting two-wire and four-wire circuits through a differential balance or bridge circuit in which the two sides of the four-wire circuit form conjugate arms.

hybrid coil—Also called bridge transformer. A single transformer which has, effectively, three windings and which is designed to be connected to four branches of a circuit so as to render these branches conjugate in pairs.

hybrid computer—A computer that results from the interconnection of an analog computer and a digital computer, plus conversion equipment, each contributing its special advantages to an assigned part of the solution of a class of complex problems.

hybrid electromagnetic wave—Abbreviated HEM wave. An electromagnetic wave having components of both electric- and magnetic-field vectors in the direction of propagation.

hybrid integrated circuit—1. An arrangement that consists of one or more integrated circuits combined with one or more discrete component parts. 2. The combination of more than one type of integrated circuit into one integrated component.

hybrid junction—1. Also called hybrid-t or magic-t. A waveguide arrangement with four branches. When they are properly terminated, energy is transferred from any one branch into two of the remaining three branches. In common usage, this energy is divided equally between the two. 2. Also called bridge hybrid, and hybrid. A transformer, resistor, or waveguide circuit or device that has four pairs of terminals so arranged that a signal entering at one terminal pair will divide and emerge from the two adjacent terminal pairs, but will be unable to reach the opposite terminal pair.

hybrid microcircuit—A microcircuit in which thin-film or diffusion techniques are combined with separately attached semiconductor chips to form the circuit.

hybrid network—A nonhomogeneous communication network required to operate with signals of dissimilar characteristics (such as analog and digital modes).

hybrid parameters—Also called h-parameters. The resultant parameters of an equivalent transistor circuit when the input current and output voltage are selected as independent variables.

hybrid ring—Also called a "rat race." A hybrid junction commonly used as an equal power divider. It consists of a re-entrant line (waveguide) to which four side arms are connected. The line is of the proper electrical length to sustain standing waves.

hybrid set—Two or more transformers interconnected to form a network having four pairs of accessible terminals. Four impedances may be connected to the four terminals, so that the branches containing them may be made conjugate in pairs.

hybrid-t—*See* Hybrid Junction.

hybrid thin-film circuit — A microcircuit formed by attaching discrete components and semiconductor devices to networks of passive components and conductors that have been vacuum deposited on glazed ceramic, sapphire, or glass substrates.

hybrid transformer—*See* Hybrid Coil.

hydroacoustics—The generation of acoustic energy from the flow of fluids under pressure.

hydroacoustic transducer — A transducer that produces high-level acoustic energy from the flow of high-pressure fluid.

hydroelectric—The production of electricity by water power.

hydrogen electrode—A platinum electrode covered with platinum black, around which a stream of hydrogen is bubbled. The hydrogen electrode furnishes a standard against which other electrode potentials can be compared.

hydrogen lamp—A special light source, used in some spectrophotometers, which produces invisible light energy. It is used in finding the light-energy frequency of test solutions.

hydrogen thyratron — A thyratron containing hydrogen.

hydromagnetics — *See* Magnetohydrodynamics.

hydromagnetic waves—Waves in which the energy oscillates between the magnetic field energy and kinetic energy of the hydrodynamic motion, the reservoirs being the self-inductance of the conductive matter and the mass inertia of the moving fluid.

hydrometer—An instrument for measuring the specific gravity of a liquid such as the electrolyte of a storage battery. It contains a graduated float which indicates the specific gravity by the amount of liquid displaced.

hydrophone — An electroacoustic transducer which responds to waterborne sound waves and delivers essentially equivalent electric waves.

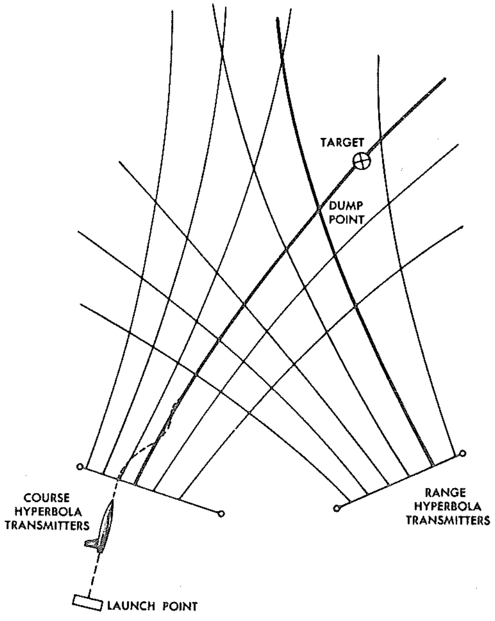
hydrostatic pressure—*See* Static Pressure.

hygrometer—An instrument that measures the relative humidity of the atmosphere.

hygroscopic—Readily absorbing and retaining moisture from the atmosphere. The opposite term is nonhygroscopic.

hygrostat—A device that closes a pair of contacts when the humidity reaches a prescribed level.

hyperacoustic zone—The region in the upper atmosphere, above about 60 miles, in which the distance between the air molecules is roughly equal to the wavelength of sound, so that sound is transmitted with less efficiency than at lower levels. Sound waves cannot be propagated above this zone.



Hyperbolic guidance.

hyperbola — 1. A curve that is the focus of points having a constant difference of distance from two fixed points. 2. In hyperbolic guidance systems, a path along which the difference between the arrival times of pulses from two transmitters is constant. (*Also see* Hyperbolic Guidance System).

hyperbolic error — The error in an interferometer system arising from the assumption that the directions of the wavefronts incident at two antennas of a base line are parallel, whereby the equiphase path is a cone. Mathematically the equiphase path is a hyperbola.

hyperbolic grind—A shape of tape playback and record heads. It permits good head contact and better response at high frequencies.

hyperbolic guidance system — A method of guidance in which sets of ground stations transmit pulses from which a hyperbolic path can be derived to give range and course information for steering. (*Also see* Hyperbola.)

hyperbolic horn—A horn in which the equivalent cross-sectional radius increases according to a hyperbolic law.

hyperbolic navigation system—A method of radionavigation (e.g., loran) in which pulses transmitted by two ground stations are received by an aircraft or ship. The difference in arrival time from each station is a measure of the difference in distance between the aircraft or ship and each station. This distance is plotted on one of many hyperbolic curves on a map. A second reading from another pair of stations (or from the same master and a different slave) establishes another point on a different hyperbolic curve. The intersection of the two curves gives the position of the aircraft or ship.

hyperfrequency waves — Microwaves having wavelengths in the range from 1 centimeter to 1 meter.

hypersonic—Having five or more times the speed of sound.

hyspersyn motor — A synchronous motor which combines the desirable features of the induction, hysteresis, and d-c excited synchronous motor, resulting in high efficiency and power factor. It possesses the vigorous starting torque of an induction motor, the synchronizating torque of a hysteresis motor, and the stiffness of an externally d-c excited synchronous motor.

hysteresigraph—A device for experimentally presenting or recording the hysteresis loop of a magnetic specimen.

hysteresis—1. The amount the magnetization of a ferrous substance lags the magnetizing force because of molecular friction. 2. A type of oscillator behavior where multiple values of the output power and/or frequency correspond to given values of an operating parameter. 3. The temporary change in the counting-rate-vs-voltage characteristic of a radiation-counter tube (caused by previous operation). 4. The difference between the response of a unit or system to an increasing and a decreasing signal. 5. A form of nonlinearity in which the response of a circuit of a particular set of input conditions depends, not only on the instantaneous values of those conditions, but also on the immediate past (recent history) of the input and output signal. Hysteretical behavior is characterized by inability to "retrace" exactly on the reverse swing a particular locus of input/output conditions.

hysteresis brake—*See* Hysteresis Clutch.

hysteresis clutch — Also called hysteresis brake. A proportional torque-control device which employs the hysteresis effect in a permanent-magnet rotor to develop its output torque. It is capable of synchronous driving or continuous slip, provided heat can be removed, with almost no torque variation at any slip differential. Its control-power requirement is small enough for vacuum-tube or transistorized drive.

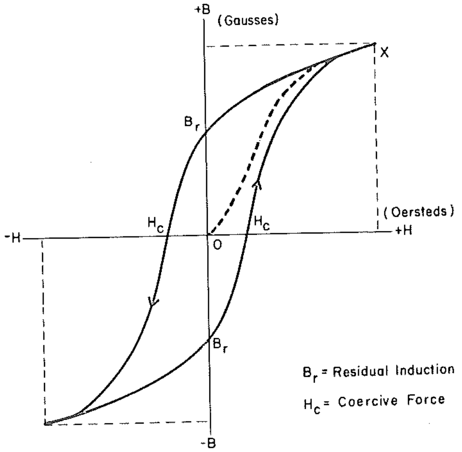
hysteresiscope—An instrument used to obtain hysteresis loops on a cathode-ray oscilloscope screen without the need for specially prepared ring samples. It is used in the inspection of magnetic material.

hysteresis curve—A curve showing the relationship between a magnetizing force and the resultant magnetic flux.

hysteresis distortion — Distortion of waveforms in circuits containing magnetic components. It is due to the hysteresis of the magnetic cores.

hysteresis error—The difference in the reading obtained on a measuring instrument containing iron when the current is increased to a definite value and when the current is reduced from a higher value to the same definite value.

hysteresis heater—An induction device in which a charge (or a muffle around the charge) is heated by hysteresis losses due to the magnetic flux produced in the charge.



Hysteresis loop.

hysteresis loop—For a magnetic material, a curve showing two values of magnetic flux density—one when the magnetizing force is increasing and the other when it is decreasing—for each value of the magnetizing force.

hysteresis loss—The power expended in a magnetic material as a result of magnetic hysteresis.

hysteresis meter—An instrument for determining the hysteresis loss in a ferromagnetic material. It measures the torque produced when the test specimen is placed in a rotating magnetic field or is rotated in a stationary magnetic field.

hysteresis motor — A synchronous motor without salient poles or direct-current excitation. It is started by the hysteresis losses induced in its secondary by the revolving field.

hystoroscope — An instrument used to observe, measure, and record the magnetic characteristics of both easy and hard axes of magnetic materials.

Hz—Abbreviation for hertz — the new term used in place of cycles per second.

I

I—1. Symbol for current. 2. Abbreviation for luminous intensity.

IC—1. Abbreviation for internal connection. 2. Abbreviation for integrated circuit.

ICBM—Abbreviation for intercontinental ballistic missile.

I_{CBO}—The reverse current that occurs when a specific d-c voltage is applied in the nonconducting directon to the collector junction of a transistor while the emitter is open-circuited.

iconoscope—A camera tube in which a beam of high-velocity electrons scans a photoemissive mosaic capable of storing an electrical charge pattern.

icw—Abbreviation for interrupted continuous wave.

ideal bunching — A theoretical condition where bunching of the electrons in a velocity-modulated tube would give an infinitely large current peak during each cycle.

ideal capacitor—A capacitor having a single-valued transferred-charge characteristic.

ideal crystal—A crystal having no mosaic structure and capable of X-ray reflection in accordance with the Darwin-Ewald-Prins law.

ideal dielectric—A dielectric in which all the energy required to establish an electric field in the dielectric is returned to the source when the field is removed. (A perfect dielectric must have zero conductivity. Also, all absorption phenomena must be lacking. A vacuum is the only known perfect dielectric.)

ideal-noise diode—A diode that has an infinite internal impedance and in which the current exhibits full shot-noise fluctuations.

ideal transducer—Theoretically, any linear passive transducer which—if it dissipated no energy and, when connected to a source and load, presented its combined impedance to each—would transfer maximum power from source to load.

ideal transformer — A hypothetical transformer which would neither store nor dissipate energy. Its self-inductances would have a finite ratio and unity coefficient of coupling, and its self- and mutual impedances would be pure inductances of infinitely great value.

I demodulator—A demodulator circuit the inputs of which are the chrominance signal and the signal from the local 3.58-MHz oscillator. The output of this demodulator is a video signal representing color in the televised scene. The Q demodulator is similar except that its input from the local oscillator is shifted 90°.

identification—1. In radar, determining the identity of a displayed target (i.e., which one of the blips in the display represents the target). 2. In a computer, a code number or code name which uniquely identifies a record, block, file, or other unit of information.

identification beacon—A code beacon used for positively identifying a particular point on the earth's surface.

identification, friend or foe—A system using radar transmissions to which equipment carried by friendly forces automatically responds, for example, by emitting pulses, thereby distinguishing themselves from enemy forces. It is the primary method of determining the friendly or unfriendly character of aircraft and ships by other aircraft or ships and by ground forces employing radar-detection equipment and associated identification, friend or foe units. Abbreviated iff.

identify—In a computer, to attach a unique code or code name to a specific unit of information.

idiochromatic — Having photoelectric properties characteristic of the pure crystal itself and not due to foreign matter.

I-display—In radar, a display in which a target appears as a circle when the radar antenna is pointed directly at it. The radius of the circle is proportionate to the target distance. When the antenna is not pointing at the target, only a segment of the circle appears. Its length is inversely proportionate to the magnitude of the pointing error, and the segment points away from the direction of error.

idle characters — Control characters interchanged by a synchronized transmitter and receiver to maintain synchronization during a nondata period.

idler—A rubber-tired wheel that transfers

power from a phonograph motor to the turntable rim.

idler pulley—A pulley used only for tightening a belt or changing its direction. The shaft does not drive any other part.

idling current—Also called quiescent current. The zero-signal power supply current drawn by a circuit or by a complete amplifier.

IEC's — *See* Integrated Equipment Components.

IEEE—A professional organization of scientists and engineers whose purpose is the advancement of electrical engineering, electronics, and allied branches of engineering and science. (The IEEE resulted from the merger of the IRE and the AIEE.)

if—Abbreviation for intermediate frequency.

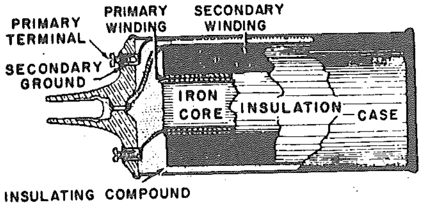
i-f amplifier — *See* Intermediate-Frequency Amplifier.

iff—*See* Identification, Friend or Foe.

IFRU—*See* Interference-Rejection Unit.

i-f strip—*See* Intermediate-Frequency Strip.

ignistor—A transistor and a matched zener diode integrated into one power package.



Ignition coil.

ignition coil—An iron-core transformer which converts a low direct voltage to the 20,000 volts or so required to produce an ignition spark in gasoline engines. It has an open core, a heavy primary winding connected to the battery or other source through a vibrating armature contact, and a secondary winding with many turns of fine wire.

ignition control—Control of the instant that static current begins to flow in the anode circuit of a gas tube.

ignition interference — Noise produced by sparks or other ignition discharges in a car, motor, or furnace ignition, or by equipment with loose contacts or connections.

ignition reserve—In a gasoline engine, the difference between the available voltage and the required ignition voltage.

ignition voltage — In a gasoline engine, the peak voltage required to produce a spark across the plug electrodes.

ignitor discharge—In switching tubes, a d-c glow discharge between the ignitor electrode and a suitably located electrode. It is used to facilitate radio-frequency ionization.

ignitor electrode—An electrode (which is partly immersed in the mercury-pool cathode of an ignitron) used to initiate conduction at the desired points in each cycle.

ignitor firing time—In switching tubes, the interval between application of a d-c voltage to the ignitor electrode and start of current flow.

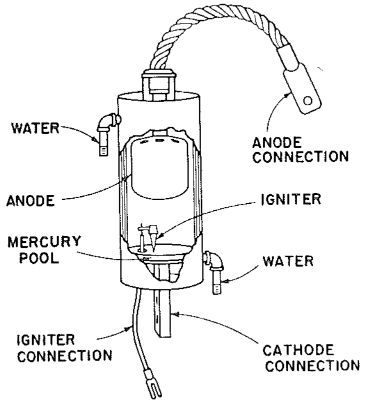
ignitor interaction—In a TR, pre-TR or attenuator tube, the difference between the insertion loss measured at a specified level of ignitor current and that measured at zero ignitor current.

ignitor leakage resistance—In a switching tube, the insulation resistance measured between the ignitor electrode terminal and the adjacent r-f electrode in the absence of an ignitor discharge.

ignitor oscillation—A relaxation type of oscillation in the ignitor circuit of a TR, pre-TR, or attenuator tube.

ignitor voltage drop—In switching tubes, the d-c voltage between the cathode and anode at a specified ignitor current.

ignitron — A type of mercury-pool rectifier which has only one anode. The arc is started for each cycle of operation by an ignitor which dips into the mercury pool. The mercury pool serves as the cathode of the rectifier. The ignitron is characterized by the ability to withstand tube currents several times as high as rated values for a few cycles.



Ignitron.

ignore—In a computer, a character code indicating that no action is to be taken.

IGY — Abbreviation for international geophysical year.

IHFM—Abbreviation for Institute of High-Fidelity Manufacturers, an association of manufacturers which publishes ratings and standards for high-fidelity equipment.

illegal character—A character which a computer system cannot properly use because the structure of the character does not agree with the machine logic. Such characters can be generated by machine failure or improper programming.

illuminance—The density of the luminous flux on a surface. It equals the flux divided by the area of the surface when uniformly illuminated.

illuminant-C—The reference white of color television — i.e., light which most nearly matches average daylight.

illuminate—1. To expose to light. 2. In radar, to strike with a radar signal so that reflection returns the signal to the source for interpretation.

illumination—The density of luminous flux (amount of light) striking a surface.

illumination control—A photo-relay circuit that turns on artificial lighting when natural illumination decreases below a predetermined level.

illumination sensitivity—The output current of a photosensitive device divided by the incident illumination at constant electrode voltages.

illuminometer—A portable photometer for measuring the illumination on a surface.

ILS — Abbreviation for instrument landing system.

image—1. The instantaneous illusion of a picture on a flat surface. 2. The unused one of the two groups of sidebands generated in amplitude modulation.

image admittance—Reciprocal of image impedance.

image antenna—The imaginary counterpart of an actual antenna. For mathematical purposes it is assumed to be located below the ground and symmetrical with the actual antenna.

image-attenuation constant—The real part of the transfer constant.

image converter—A solid-state optoelectric device capable of changing the spectral characteristics of a radiant image. Examples of such changes are infrared-to-visible and X-ray-to-visible.

image-converter tube—*See* Image Tube.

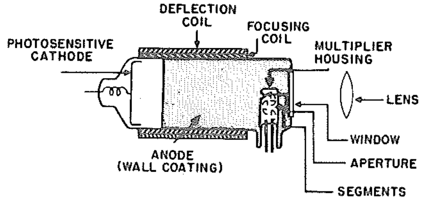


Image dissector.

image dissector—A television camera tube in which the image is swept past an aperture in a series of 525 interlaced lines thirty times per second. Instead of a beam scanning the image, the entire image is scanned past the aperture, which "dissects" the image—hence, the name. (*Also see* Dissector Tube.)

image distortion—Failure of the reproduced image in a television receiver to resemble the original scene scanned by the camera.

image effect—An effect produced on the field of an antenna as the electromagnetic waves are reflected from the earth's surface.

image force—The force on a charge due to that charge or polarization which it induces on neighboring conductors or dielectrics.

image frequency — In heterodyne frequency converters, an undesired input frequency capable of producing the selected frequency by selecting one of the two sidebands produced by beating. The word "image" implies the mirrorlike symmetry of signal and image frequencies about the beating oscillator frequency or intermediate frequency, whichever is higher.

image-frequency rejection ratio—Of a superheterodyne receiver, the ratio of the response at the desired frequency to the response at the image frequency.

image iconoscope—An iconoscope in which greater sensitivity is obtained by separating the function of charge storage from that of photoelectric emission. An optical image is projected on a continuous photosensitive screen, and the electron emission from the back of this screen is focused electromagnetically onto a mosaic screen that is scanned by an electron beam as in the original emitron cathode-ray tube. The British term is super-emitron.

image impedance—The impedances which will simultaneously terminate all inputs and outputs of a transducer in such a way that at each of its inputs and outputs the impedances in both directions are equal.

image intensifier — A system for increasing the sensor response to a radiation pattern or image by interposing active elements between the sensor and the image, and supplying power to the active element. This is normally done by focusing the scene to be imaged on the photocathode of the tube, giving rise to a photoelectron pattern corresponding to the optical image. This pattern is accelerated and focused onto a phosphor which emits light to reproduce a visual image of the scene.

image interference—In a receiver, a response due to signals of a frequency removed from the desired signal by twice the intermediate frequency.

image-interference ratio—In a superheterodyne receiver, the effectiveness of the preselector in rejecting signals at the image frequency.

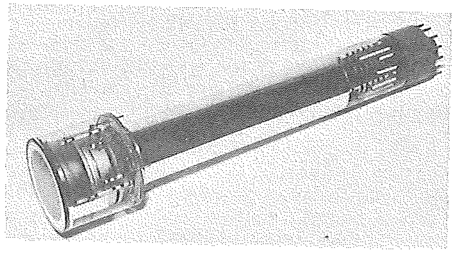

Image orthicon.

image orthicon—A camera tube in which a photoemitting surface produces an electron image and focuses it on one side of a separate storage target. The opposite side of the target is then scanned by low-velocity electrons to produce the output.

image phase constant—The imaginary part of the transfer constant.

image ratio—In a heterodyne receiver, the ratio of the image-frequency signal input to the desired signal input for identical amplitude outputs.

image rejection—The suppression of image-frequency signals in a superheterodyne receiver.

image response—The response of a heterodyne receiver to a signal that is separated by twice the intermediate frequency from the frequency to which the receiver is tuned. Unless there is some preselection, images will cause spurious unwanted responses when the spectrum occupied by a signal is greater than twice the frequency of the first i-f stage of the receiver.

image-transfer constant—*See* Transfer Constant.

image tube—Also called an image-converter tube. An electron tube which reproduces on its fluorescent screen an image of an irradiation pattern incident on its photosensitive surface.

immersion pyrometer — An instrument for determining molten-steel temperature and normally consisting of a platinum-platinum rhodium bimetal thermocouple junction and a recording device for transposing the millivoltage into degrees of temperature.

impact excitation—The starting of damped oscillations by a sudden surge, such as by a spark discharge.

impact predictor—A device which can determine, in real time, the point on the earth's surface where a ballistic missile will impact if thrust is instantaneously terminated.

impedance—The total opposition (i.e., resistance and reactance) a circuit offers to the flow of alternating current. It is measured in ohms, and its reciprocal is called admittance.

impedance angle — Angle of the impedance vector with respect to the resistance vector. Represents the phase angle between voltage and current.

impedance bridge — A device for measuring the combined resistance and reactance of a component part of a circuit.

impedance characteristic—A graph of impedance versus frequency of a circuit or component.

impedance coil—A coil in which its inductive reactance is used to hinder the flow of alternating current in or between circuits.

impedance compensator—An electric network used with a line or another network to give the impedance of the combination a certain characteristic over a desired frequency range.

impedance coupling—A method of coupling using an impedance as the coupling device, common to both the primary and secondary circuits. This type of coupling is usually limited to audio systems, where high gain and limited bandpass are required.

impedance drop—The vector sum of the resistance drop and the reactance drop. (For transformers, the resistance drop, the reactance drop, and the impedance drop are, respectively, the sum of the primary and secondary drops reduced to the same terms. They are usually expressed in percent of the secondary-terminal voltage.)

impedance irregularities—Breaks or abrupt changes which occur in an impedance-frequency curve when unlike sections of a transmission line are joined together or when there are irregularities on the line.

impedance matching—The connection across a source impedance of another impedance having the same magnitude and phase angle. If the source is a transmission line, reflection is thereby avoided.

impedance-matching transformer—A transformer used to match the impedance of a source and load.

impedance transformer—A transformer that transfers maximum energy from one circuit to another.

impedance triangle—A diagram consisting of a right triangle. The sides are proportional to the resistance and reactance in an a-c circuit, with the hypotenuse representing the impedance.

imperfect dielectric—A dielectric in which part of the energy required to establish its electric field is converted into heat instead of being returned to the electric system when the field is removed.

imperfection (of a crystalline solid)—Any deviation in structure from an ideal crystal (one which is perfectly periodic in structure and contains no foreign atoms).

implode—The inward bursting of a picture tube due to its high vacuum.

impregnated coils—Coils that have been permeated with an electric grade varnish or other protective material to protect them from mechanical vibration, handling, fungus, and moisture.

impregnation—The process of coating the insides of coils and closely packed electronic assemblies by dipping them into a liquid and letting it solidify.

impressed voltage—The voltage applied to a circuit or device.

improvement threshold—A characteristic of f-m radio receivers which determines the minimum r-f signal power required to overcome the inherent thermal noise. For increasing values of r-f power above this point, an improvement of signal-to-noise ratio is obtained.

impulse—A pulse that begins and ends within so short a time that it may be regarded mathematically as infinitesimal. The change produced in the medium, however, is generally of a finite amount. (*Also see* Pulse.)

impulse bandwidth — The area divided by the height of the voltage-response selectivity curve as a function of frequency. It is used in the calculation of broad-band interference.

impulse-driven clock—An electric clock in which the hands are moved forward at regular intervals by current impulses from a master clock.

impulse excitation—Also called shock excitation. A method of producing oscillatory current in which the duration of the impressed voltage is relatively short compared with that of the current produced.

impulse frequency—The number of pulse periods per second generated by the dial-pulse springs in a telephone as they rapidly open and close in response to the dialing of a digit.

impulse generator—1. Also called surge generator. An electric apparatus that produces high-voltage surges for testing insulators and for other purposes. 2. A device that generates a broad energy spectrum by means of a very narrow impulse. Usually generated by discharging a short coaxial or waveguide transmission line. The pulses are discrete and regularly spaced, and are generally variable at a repetition rate from a few pulses per second to a few thousand pulses per second. The output of an impulse generator is specified as the rms equivalent of the peak voltage in db above 1 microvolt per megahertz. 3. An oscillator circuit that generates electric impulses for synchronizing purposes in a television system.

impulse noise — Noise due to disturbances having abrupt changes and of short duration. (These noise impulses may or may not have systematic phase relationships. The noise is characterized by nonoverlapping transient disturbance. The same source may produce impulse noise in one system and random noise in a different system.)

impulse-noise generator — Equipment for generating repetitive pulses which provide random noise signals uniformly spread over a wide band of frequencies.

impulse ratio — The ratio of the flashover, sparkover, or breakdown voltage of an impulse to the crest value of the power-frequency flashover, sparkover, or breakdown voltage.

impulse relay—1. A relay that stores enough energy from a brief impulse to complete its operation after the impulse ends. 2. A relay that can distinguish between different types of impulses, operating on long or strong impulses, and not operating on short or weak ones. 3. An integrating relay.

impulse sealing—A heat-sealing technique in which a pulse of intense thermal energy is applied to the sealing area for a very short time, followed immediately by cooling. It is usually accomplished by using an r-f heated metal bar which is cored for water cooling, or is of such a mass that it will cool rapidly at ambient temperatures.

impulse separator — Normally called sync separator. In a television receiver, the circuit that separates the synchronizing impulses from the video information in the received signal.

impulse speed—The rate at which a telephone dial mechanism makes and breaks the circuit to transmit pulses.

impulse timer—A timing device electrically powered by a synchronous motor, featuring a mechanical stepping device which enables it to advance a predetermined number of degrees within a predetermined time interval, controlling a multiple number of circuits. Said circuits are controlled by individual cams which program their activity.

impulse train—*See* Pulse Train.

impulse transmission—The form of signaling used principally to reduce the effects of low-frequency interference. Impulses of either or both polarities are employed for transmission, to indicate the occurrence of transitions in the signals.

impulse-transmitting relay — A relay in which a set of contacts closes briefly when the relay changes from the energized to the de-energized position, or vice-versa.

impulse-type telemeter—A telemeter which employs the characteristics of intermittent electric signals, other than their frequency, as the translating means.

impurity—An atom that is foreign to the crystal in which it exists. Material added to a semiconductor crystal to produce excess electrons (a donor impurity) or excess holes (an acceptor impurity).

impurity density—The amount of impurity material diffused into a certain volume of semiconductor material used in manufacturing semiconductor devices.

impurity level—The energy level existing in a substance because of impurity atoms.

inaccuracy — 1. The difference between the input quantity applied to a measuring instrument and the output quantity indicated by that instrument. The inaccuracy of an instrument is equal to the sum of its instrument error and its uncertainty. 2. The term sometimes used to indicate the deviation from an indicated or recorded value or the measure of conformity to an accepted standard.

inactive leg—Within a transducer, an electrical element which does not change its electrical characteristics with the applied stimulus. Applied specifically to elements that complete a Wheatstone bridge in certain transducers.

in-band signaling—The transmission of signaling tones at some frequency or frequencies within the channel normally used for voice transmission.

incandescence—The state of a body with such a high temperature that it gives off light.

incandescent lamp — An electric lamp in which electric current flowing through a filament of resistance material heats the filament until it glows.

INCH—Acronym for INtegrated CHopper. It is a device designed to operate as a chopper, commutator, modulator, demodulator, or mixer, depending on circuit requirements.

inching—*See* Jogging.

incidence angle—The angle between an approaching light ray or emission and the perpendicular (normal) to the surface in the path of the ray.

incidental f-m—Also called residual f-m. The short-term jitter or undesired f-m deviation of a local oscillator. It limits resolution when it approaches the i-f bandwidth in magnitude.

incident field intensity—The field strength of a down-coming sky wave, not including the effects of earth reflections at the receiving location.

incident wave—In a medium of certain propagation characteristics, a wave which strikes a gap in the medium or strikes a medium having different propagation characteristics.

incipient failure — A degradation failure in its beginning stages.

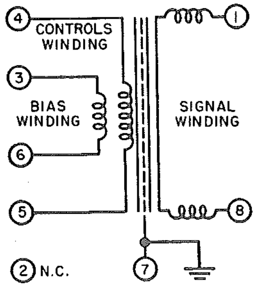
inclination—The angle which a line, surface, or vector makes with the horizontal.

inclinometer—An instrument for measuring the magnetic inclination of the earth's magnetic field. It uses a magnetic needle that pivots vertically to indicate the inclination.

incoherent detection—Detection wherein the information contained in the phase of the carrier is discarded.

incoherent scattering — The disordered change in their direction of propagation when radio waves encounter matter.

incomplete sequencer relay — A device which returns the equipment to the normal, or off, position and locks it out if the normal starting, operating, or stopping sequence is not properly completed within a predetermined time.



Increductor.

increductor—A controllable inductor similar to a saturable reactor, except that it is capable of operating at high frequencies (e.g., up to 400 MHz).

increment—A small change in value.

incremental hysteresis loss — Losses in a magnetic material that has been subjected to a pulsating magnetizing force.

incremental induction—One half the algebraic difference between the maximum and minimum magnetic induction at a point in a material which has been subjected simultaneously to a polarizing and a varying magnetizing force.

incremental permeability — Ratio of the cyclic change in magnetic induction to the corresponding cyclic change in magnetizing force when the mean induction is other than zero.

incremental sensitivity—The smallest change that can be detected by a particular instrument in a quantity under observation.

incremental tuner—A television tuner in which antenna, r-f-amplifier and r-f-oscillator inductors are continuous or in small sections connected in series. Rotary switches, connected to taps on the inductors, provide the portion of total inductance required for a channel, or short-circuit all remaining inductance except that required for the channel.

independent failure—A failure which has no significant relationship to other failures in a given device and can occur without interaction with other component parts in the equipment.

independent load contacts—Contacts which can control electrical loads that must be isolated from the timer clutch solenoid and motor circuit.

independent variable—One of several voltages and currents chosen arbitrarily and considered to vary independently.

index counter—An odometer-type counter which shows the amount of tape that has been unreeled on a recorder. In this way, the operator is able to note the location of a particular selection on the tape.

indexing—In a computer, a technique of address modification that is often implemented by means of index registers.

indexing slots—*See* Polarizing Slots.

index of cooperation—In facsimile, the product of the diameter of the scanning drum multiplied by the number of scanning lines per inch.

index of modulation—The modulation factor.

index of refraction—Ratio of the speeds of light or other radiation in two different materials. This determines the amount the ray will be refracted or bent when passing from one material to the other, such as from air to water.

index register — In a computer, a register that holds a quantity which may be used for modifying addresses or for other purposes, as directed by the program.

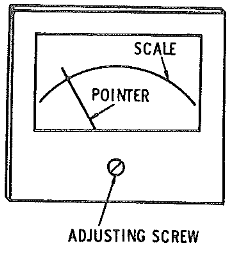
indicating demand meter—A meter equipped with a scale over which a pointer is advanced to indicate maximum demand.

indicating fuse—A protective device placed in a telephone circuit to provide visual and audible indication of a fault in the line. It consists of a fuse, pilot lamp, relay, and buzzer. When a line fault blows the fuse, the lamp lights and the buzzer sounds.

indicating instrument—An instrument which visually indicates only the present value of the quantity being measured.

indicating lamp—A lamp which indicates the position of a device or the condition of a circuit.

indicating meter — A meter which gives a visual indication of only the present or short-time average value of the measured quantity.



Indicating meter.

indication—The display to the human senses of information concerning a quantity being measured.

indicator—An instrument that makes information available, but does not store it.

indicator gate—A rectangular voltage waveform applied to the grid or cathode circuit of an indicator cathode-ray tube to sensitize or desensitize the tube during the desired portion of the operating cycle.

indicator tube—An electron-beam tube which conveys useful information by the variation in cross section of the beam at a luminescent target.

indirect-acting recording instrument — An instrument in which the marking device is actuated by raising the level of measurement energy of the primary detector. This is done mechanically, electrically, electronically, photoelectrically, or by some other intermediate means.

indirect addressing—A method of computer cross reference in which one memory location indicates where the correct address of the main fact can be found.

indirect light—Light from an object which has no self-luminous properties. Instead, it reflects light from another source.

indirectly controlled variable — A variable that is related to and influenced by the directly controlled variable but is not directly measured for control.

indirectly heated cathode—Also called equipotential or unipotential cathode. A cathode which is heated by an independent heater.

indirectly heated thermistor—A thermistor which incorporates, as part of its composite structure, an electrical heater. A thermistor the body temperature of which in use is significantly higher than the temperature of its surrounding medium as a result of current passing through its heater.

indirect piezoelectricity — The production of a mechanical strain in a crystal by applying a voltage to it (as opposed to the more common piezoelectric effect of applying a strain to the crystal in order to produce a voltage).

indirect scanning — A television technique used in early mechanical systems, and today in the flying-spot scanning of films. A small beam of light is moved across the subject and then reflected to a battery of phototubes.

indirect wave—A wave reaching a given reception point by a path from the transmitting point other than the direct-line path between the two (e.g., a sky wave received after deflection from the ionosphere layers).

individual gap azimuth—In a magnetic-tape record or reproduce head stack, the angle of an individual gap relative to a line perpendicular to the precision milled mounting pads in a plane parallel to the surface of the tape.

indoor antenna—Any receiving antenna located inside a building but outside the receiver.

indoor transformer—A transformer which must be protected from the weather.

induced—Produced by the influence of an electric or magnetic field.

induced charge—An electrostatic charge produced in one object by the electric field surrounding a nearby object.

induced current—1. The current that flows in a conductor which is moved perpendicularly to a magnetic field, or which is subjected to a magnetic field of varying intensity. The former takes place in an induction-motor rotor; the latter, in the secondary winding of a transformer. 2. In induction heating, the current that flows in a conductor when a varying electromagnetic field is applied.

induced electromotive force — Represented by E and is proportional to the rate of change of magnetic flux through the circuit ($d\phi/dt$).

induced environment — The temperatures, vibrations, shocks, accelerations, pressures, and other conditions imposed on a system due to the operation or handling of the system.

induced failure — A failure that is basically caused by a condition or phenomenon external to the item that fails.

induced voltage—The voltage produced in a conductor when the conductor is moved up and down through the magnetic field of a second conductor, or when the field varies in intensity and cuts across the first conductor. Even though there is no mechanical coupling between the two conductors, the one producing the field will produce a voltage in the other.

inductance—In a circuit, the property which opposes any change in the existing current. Inductance is present only when the current is changing.

inductance bridge—An instrument, similar to a Wheatstone bridge, for measuring an unknown inductance by comparing it with a known inductance.

inductance coil—*See* Inductor.

inductance-tube modulation—A method of modulation employed in frequency-modulated transmitters. An oscillator control tube acts as a variable inductance in parallel with the tank circuit of the radio-frequency oscillator tube. As a result, the oscillator frequency varies in step with the audio-frequency voltage applied to the grid of the oscillator control tube.

induction—1. The establishment of an electric charge of a magnetic field in a substance by the proximity of an electrified source, a magnet, or a magnetic field. 2. The setup of an electromotive force and current in a conductor by variation of the magnetic field affecting the conductor.

induction brazing — The electric brazing process in which heat is produced by an induced current.

induction coil—1. A device for changing direct current into high-voltage alternating current. Its primary coil contains relatively few turns of heavy wire; and its secondary coil, wound over the primary, contains many turns of fine wire. Interruption of the direct current in the primary by a vibrating-contact arrangement induces a high voltage in the secondary.

induction compass—A compass in which the indications are produced by the current generated in a coil revolving in the magnetic field of the earth.

induction-conduction heater—A heating device through which electric current is conducted but is restricted by induction to a preferred path.

induction density—*See* Flux Density.

induction factor—In an alternating current circuit, the ratio between that element of the current which does no work and the total strength of the current.

induction field—1. That portion of the electromagnetic field of a transmitting antenna which acts as if it were permanently associated with the antenna, and into which energy is alternately stored and removed. 2. The electromagnetic field of a coil carrying alternating current, responsible for the voltage induced by that coil in itself or in a nearby coil.

induction frequency converter—A slip-ring induction machine driven by an external source of mechanical power. Its primary circuits are connected to a source of electric energy having a fixed frequency. The energy delivered by its secondary circuits is proportionate in frequency to the relative speed of the primary magnetic field and the secondary member.

induction furnace—A furnace heated by electromagnetic induction.

induction hardening—The process of hardening the surface of a casting by heating it above the transformation range by electrical induction, followed by rapid cooling.

induction heating—The method of producing heat by subjecting a material to a variable electromagnetic field. Internal losses in the material then cause it to heat up.

induction instrument—An instrument operated by the reaction between the magnetic flux set up by one or more currents in fixed windings and the currents set up by electromagnetic induction in movable conductive parts.

induction motor — An alternating-current motor in which the primary winding (usually the stator) is connected to the power source and induces a current into a polyphase secondary or squirrel-cage secondary winding (usually the rotor).

induction-motor meter—A meter containing a rotor that moves in reaction to a magnetic field and the currents induced into it.

induction noise — The noise—other than thump, flutter, cross fire or cross talk—produced when two circuits are inductively coupled together.

induction-resistance welding—Welding in which electromagnetic induction alone causes the heating current to flow in the parts being welded.

induction-ring heater—A core-type induction heater adapted principally for heating round objects. The core is open or can be taken off to facilitate linking the charge.

induction speaker—A speaker in which the current that reacts with the steady magnetic field is induced into the moving member.

induction-voltage regulator—A device having a primary winding in shunt, and a secondary winding in series with a circuit for gradually adjusting the voltage or the phase relation of the circuit by changing the relative position of the exciting and series windings of the regulator.

inductive—Pertaining to inductance or to the inducing of a voltage through mutual or electrostatic induction.

inductive circuit—A circuit with more inductive than capacitive reactance.

inductive coupling—The association of two or more circuits solely by the mutual inductance between them.

inductive feedback—1. The transfer of energy from the plate circuit to the grid circuit of a vacuum tube by induction. 2. The transfer of energy from the output circuit to the input circuit of an amplifying device through an inductor or inductive coupling.

inductive interference — Interference produced in communication systems by induced voltages within the system.

inductive kick — The voltage, many times higher than the impressed voltage, produced by the collapsing field in a coil when the current through it is abruptly cut off.

inductive load—Also called lagging load. A load that is predominantly inductive, so that the alternating load current lags behind the alternating voltage of the load.

inductively coupled circuit—A network with two meshes having only mutual inductance in common.

inductive microphone—*See* Inductor Microphone.

inductive neutralization—Also called shunt or coil neutralization. A method of neutralizing an amplifier, whereby the equal and opposite susceptance of an inductor cancels the feedback susceptance caused by interelement capacitance.

inductive pickup—Signals generated in a circuit or conductor due to mutual inductance between it and a disturbing source.

inductive reactance—The opposition to the flow of alternating or pulsating current by the inductance of a circuit. It is measured in ohms, and its symbol is X_L. It is equal to 2π times the frequency in hertz times the inductance in henrys.

inductive transducer—A transducer in which changes in inductance convey the stimulus information.

inductive transduction—The conversion of the measurand into a change in the self-inductance of a single coil.

inductive tuning—A method of tuning a radio by moving a core into and out of a coil to vary the inductance.

inductive winding—A coil through which a varying current is sent to give it an inductance.

inductor—Also called inductance or retardation coil. A conductor used for introducing inductance into an electric circuit. The conductor is wound into a spiral, or coil, to increase its inductive intensity.

inductor microphone—Also called inductive microphone. A microphone in which the sound waves move a conductor back and forth, cutting magnetic lines of force and producing an electrical output of the same frequency and proportional to the amplitude of the sound waves.

inductor-type synchronous motor — A type of synchronous motor having field magnets that are fixed in magnetic position relative to the armature conductors, the torques being produced by forces between the stationary poles and salient rotor teeth. Such motors usually have permanent-magnet field excitation, are built in fractional-horsepower frames, and operate at low speeds (300 revolutions per minute or less).

inductosyn—An extremely precise transducer based upon the magnetic circuit of a conductor deposited on glass for stability, and operated at a relatively high frequency. Extremely accurate, but requires much auxiliary equipment (Farrand Controls Inc.).

industrial radio services — Radiocommunication services essential to, operated by, and for the sole use of those enterprises which require radiocommunications in order to function efficiently.

industrial television — Television used for remote viewing of manufacturing or assembling processes, usually over cables rather than through the air.

industrial timer—A timing device, impulse or constant-speed type, used in industrial applications other than the appliance industry.

industrial tube—A vacuum tube designed for industrial electronic equipment.

inelastic collision—Collision resulting in excitation of a molecule.

inertance—Acoustical equivalent of inductance.

inert gas—*See* Noble Gas.

inertia—The tendency of an object at rest to remain at rest, or of a moving object to continue moving in the same direction and at the same speed, unless disturbed by an outside force.

inertial guidance—The automatic guidance system used in missiles and satellites to make them follow a predetermined trajectory without assistance from the ground. Gyroscopes, accelerometers, and possibly a gyro-stabilized platform are used.

inertial navigation—A guidance technique in which air-frame acceleration is first measured and then integrated twice with respect to time in order to determine the distance traveled. External aids such as radio and radar are not necessary. The acceleration or deceleration of the air frame is measured continuously with accelerometers oriented in some convenient frame of reference, usually corresponding to the earth's north-south, east-west coordinates.

inertia relay—A relay having added weights or other modifications that increase its moment of inertia and either slow it or cause it to continue in motion after the energizing force is removed.

inertia switch—A switch capable of sensing acceleration, shock, or vibration.

infant mortality—The occurrence of premature catastrophic-type failures at a rate substantially greater than that observed during life prior to wearout.

infant-mortality period — *See* Early-Failure Period.

inferential—The kind of instrumentation, especially its signal source, in which there is sampling of an entirely different quantity from the one of interest, upon assuming that they vary in perfect proportion. Linearity or a perfectly repeatable relationship between the two is inferred, for the sake of a more convenient signal-source arrangement.

infinite—Boundless; having no limits whatsoever.

infinite baffle—A speaker enclosure with no openings through which sound waves can travel from the front of the cone to the back.

infinite-impedance detector—A detector circuit in which the load is a resistor connected in parallel with an r-f bypass capacitor between the cathode and ground. Since the grid is always negative with respect to the cathode, the tube presents an infinite impedance to the input.

infinite line—A transmission line with the same characteristics as an ordinary line that is infinitely long.

infinite resolution—The capability of a device to provide continuous output over its entire range.

infinitesimal — Immeasurably small; approaching zero.

infinity—1. A hypothetical amount larger than any assignable amount. 2. A number larger than any number a computer can store in any register.

inflection point—The point where a curve changes direction.

information—In computing, the basic data and/or program entered into the system.

information channel—The transmission and intervening equipment involved in the transfer of information in a given direction between two terminals. An information channel includes the modulator and demodulator and any error-control equipment irrespective of its location, as well as the backward channel, when provided.

information gate — A circuit that permits information or data pulses from passing when the circuit is triggered by an external source.

information handling — The storing and processing of information and its transmission from the source to the user. Information handling excludes the creation and use of information.

information rate—In computers, the minimum number of binary digits per second required to specify the source messages.

information rate changer — A device that speeds up the playback of tape-recorded speech without pitch change or deterioration of characteristic resonances. This is accomplished by rotating the playback head in the direction of tape travel.

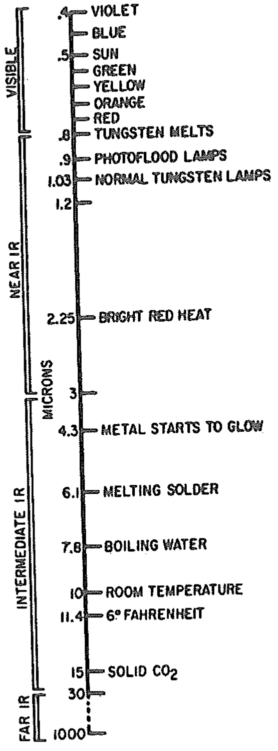
information retrieval — A method for cataloging vast amounts of data related to one field of interest so that any part or all of this data can be called out at any time with accuracy and speed.

infrared—A form of electromagnetic radiation similar to visible light and radio waves. It is generated by thermal agitation and radiated by everything with a temperature above absolute zero (−273°C). High temperatures increase the thermal agitation. Hence, the hotter the object, the greater the infrared radiation. Abbreviated IR.

infrared counter-countermeasures—Action taken to employ infrared radiation equipment and systems in spite of enemy measures to counter their use.

infrared countermeasures—Action taken to reduce the effectiveness of enemy equipment employing infrared radiation.

infrared detector — A transducer which is sensitive to invisible infrared radiation (wavelength between 0.75 and 1000 microns), usually using a semiconductor, thermocouple bolometer, or pneumatic (pressure) device to detect the radiation.



Infrared spectrum.

infrared guidance—A system using infrared heat resources for reconnaissance of targets or for navigation.

infrared homing—A type of missile homing in which the guidance system tracks the target from the infrared radiation it emits.

infrared light—Light rays just below the red end of the visible spectrum.

infrared optics — Lenses, prisms, and other optical elements for use with infrared radiation (radiation with a wavelength between 0.75 and 1000 microns).

infrared radiation — Heat radiation with wavelengths slightly longer than those of visible red (i.e., 0.75 to 1000 microns).

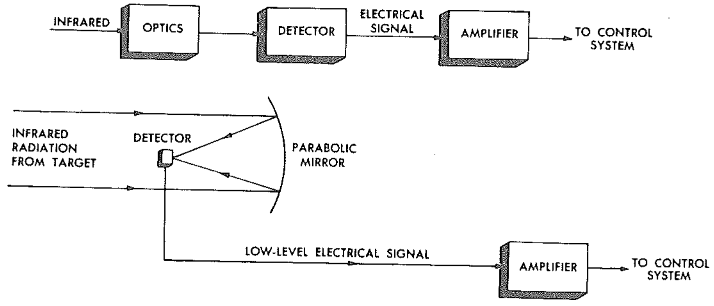
infrared sources—Emitters of radiation with a wavelength between 0.75 and 1000 microns.

infrared waves—Also called black light. Invisible waves longer than the longest visible red light waves but shorter than radio-frequency waves.

infrared window—A region of relatively high transmission in the infrared-frequency range.

infrasonic—Pertaining to frequencies below the range of human hearing, hence below about 15 hertz. Formerly called subsonic.

infrasonic frequency—Also called subsonic



Infrared guidance.

frequency. A frequency below the audio range. Infrasonic vibrations can be felt but not heard.

inharmonic frequency—A frequency which is not a rational multiple of another frequency.

inherent delay—Delay between the insertion of information into a unit and presentation of the information at the output. Delay is usually inserted into the crt vertical amplifier of pulse analyzers to allow the leading edge of the signal triggering the sweep to be seen.

inherent interference—A type of electromagnetic interference generated within a receiver by thermal agitation, shot effect, and nonlinear impedance.

inherited error—In a computer, the error in the initial values, especially that error accumulated from prior steps in a step-by-step integration.

inhibit gate—A circuit that provides an output when the inputs differ and only for one of these combinations. This function can be implemented directly or by using any previous gate, plus an inverter.

inhibiting input—A computer gate input which, if in its prescribed state, prevents any output which might otherwise occur.

inhibition gate—A gate circuit used as a switch and placed in parallel with the circuit it is controlling.

inhibit pulse—A computer drive pulse that tends to prevent certain drive pulses from reversing the flux of a magnetic cell.

initial actuation time—The time of the first closing of a previously open contact of a relay or the first opening of a previously closed contact.

initial contact chatter—That chatter caused by vibration produced by opening or closing the contacts in a relay themselves, as by contact impact in closure.

initial differential capacitance—The differential capacitance of a nonlinear capacitor when the capacitor voltage is zero.

initial drain—The current supplied at nominal voltage by a cell or battery.

initial element—*See* Primary Detector.

initial erection—The mode of operation of a vertical gyro in which the gyro is being erected or slaved initially. The initial erection rate is usually relatively fast.

initial failure—The first failure that occurs in use.

initial inverse voltage—Of a rectifier tube, the peak-inverse anode voltage immediately following the conducting period.

initial ionizing event—Also called primary ionizing event. An ionizing event that initiates a tube count.

initializing—The preliminary steps in arranging those instructions and data in a computer memory that are not to be repeated.

initial permeability—Permeability at a field density approaching zero.

initial reversible capacitance—In a nonlinear capacitor, the reversible capacitance at a constant bias voltage of zero.

initial-velocity current—A current which flows between an electrode, such as the grid of a vacuum tube, and its cathode as a result of electrons thrown off from the cathode because of heat alone. Their velocity is sufficient to allow the electrons to reach the grid unaided by an accelerating field.

injected lasers—*See* Diode Laser.

injection grid—A vacuum-tube grid that controls the electron stream without causing interaction between the screen and control grids. In some superheterodyne receivers, the injection grid introduces the oscillator signal into the mixer stage.

injection laser—A semiconductor diode in which radiation is produced as electrons recombine with holes in the junction region. For coherent emission, the current density must exceed a certain threshold value, commonly about 10,000 amperes per square centimeter for gallium-arsenide diodes.

injector—An electrode on a spacistor.

ink-mist recording—Also called ink-vapor recording. In facsimile, electromechanical recording in which particles of an ink mist are deposited directly onto the record sheet.

ink recorder—The ink-filled pen or capillary tube that produces a graphic record.

ink recording—A type of mechanical facsimile recording in which an inked helix marks the record sheet.

ink-vapor recording—*See* Ink-Mist Recording.

inleads—Those portions of the electrodes of a device that pass through an envelope or housing.

in-line heads—*See* Stacked Heads.

in-line tuning—The method of tuning the intermediate-frequency strip of a superheterodyne receiver in which all the intermediate-frequency amplifier stages are made resonant to the same frequency.

inorganic electrolyte—A solution that conducts electricity due to the presence of ions of substances not of organic origin.

in phase—Two waves of the same frequency that pass through their maximum and minimum values of like polarity at the same instant, are said to be in phase.

in-phase portion of the chrominance signal.—That portion of the chrominance signal having the same phase as, or exactly the opposite phase from, that of the subcarrier modulated by the I-signal. This portion of the chrominance signal may lead or lag the quadrature portion by 90 electrical degrees.

input—1. The current, voltage, power, or other driving force applied to a circuit or device. 2. The terminals or other places where current, voltage, power, or driving force may be applied to a circuit or device.

input admittance—1. The reciprocal of input impedance. 2. The admittance between the input terminals with the outputs shorted together.

input area—In a computer, the area of internal storage into which data from external storage is transferred.

input block—In a computer, a section of the internal storage reserved for receiving and processing input data.

input capacitance—The sum of the direct capacitances between the control grid and cathode (and any other electrodes operated at the alternating potential of the cathode). This is not the effective capacitance, which is a function of the impedances of the associated circuits.

input common-mode rejection ratio—1. The ratio of the change in input voltage to the corresponding change in output voltage, divided by the open-loop voltage gain. 2. The ratio of the full differential voltage gain to the common-mode voltage gain.

input equipment—The equipment that introduces information into a computer.

input error voltage—The error voltage appearing across the input terminals of an operational amplifier when a feedback loop is applied around the amplifier.

input extender—A high-speed diode array used in a logic circuit when increased fan-in capability is required.

input gap—Also called buncher gap. In a microwave tube, the gap where the initial velocity modulation of the electron stream occurs.

input impedance—The impedance a transducer presents to a source.

input impedance of a transmission line—The impedance between the input terminals with the generator disconnected.

input-output devices—Computer hardware by which data is entered into a computer or by which the finished computations are recorded for immediate or future use. Abbreviated I/O.

input-power rating—Also called coil rating. A statement of the allowable voltage, current, or power to the actuating element of a relay beyond which unsatisfactory performances will occur.

input recorder—Any device which makes a record of an input electrical signal.

input register—In a computer, the register of internal storage able to accept information from outside the computer at one speed and supply the information to the computer calculating unit at another, usually much greater, speed.

input resonator—The buncher resonator in a velocity-modulated tube. It modifies the velocity of the electrons in the beam.

input transformer—A transformer that transfers energy from an alternating-voltage source to the input of a circuit or device. It usually provides the correct impedance match, too.

input uncertainty—In an operational amplifier, the algebraic sum of all the factors, including environmental and time effects, that contribute to the nonideal behavior of the input circuit.

input unit—In a computer, the unit that takes information from outside the computer into the computer.

input voltage offset—The d-c potential difference between the two inputs of a differential amplifier when the potential between the output terminals is zero.

input winding—*See* Signal Winding.

inquiry station—In a computer, a direct method of reading data from or entering data into storage.

inquiry unit—A device used to extract a quick reply to a random question regarding information in a computer storage.

inrush current—In a solenoid or coil, the steady-state current drawn from the line with the armature in its maximum open position.

insert core—An iron core used generally for adjusting an inductor to a fixed frequency. It consists of a threaded metal insert molded or cemented into one or both ends of the core.

insert earphones—Small earphones which fit partially inside the ear.

insertion gain—The gain resulting from the insertion of a transducer in a transmission system is the ratio of the power delivered to that part of the system following the transducer to the power delivered to that same part before insertion. (If more than one component is involved in the input or output, the particular component used must be specified. This ratio is usually expressed in decibels.)

insertion loss—1. The difference between the power received at the load before and after the insertion of apparatus at some point in the line. 2. Ratio in decibels of the power received at the load before and after insertion of the apparatus.

insertion phase shift—The change in phase of an electric structure when inserted into a transmission system.

inside lead—*See* Start Lead.

inside spider—A flexible device placed inside a voice coil to center it with the pole pieces of a speaker.

inspection chamber—In a spectrophotometer, the part in which the solution to be tested is placed for analysis.

inspectoscope—An instrument for viewing quartz crystals, while they are immersed in oil, to determine mechanical faults, the approximate direction of the optical axis, and regions of optical twinning.

instability—The measure of the fluctuations or irregularities in the performance of a device, system, or parameter.

instantaneous automatic gain control—In radar, an automatic gain control which instantly responds to variations in the mean clutter level and thereby reduces it.

instantaneous automatic volume control—A fast-acting automatic volume-control circuit installed in some radar receivers as an anticlutter device.

instantaneous companding — Companding which varies the effective gain in response to instantaneous values of the signal wave.

instantaneous contacts—Contacts which are actuated immediately when a starting signal is applied to a timer.

instantaneous disc—A blank recording disc that can be played back on a phonograph immediately after being cut on a recorder.

instantaneous frequency—The rate at which the angle of a wave changes when the wave is a function of time. If the angle is measured in radians, the frequency in hertz is the rate of change of the angle divided by 2π.

instantaneous overcurrent relay — Also called rate-of-rise relay. A device which functions instantaneously on an excessive value of current, or on an excessive rate of current rise, thus indicating a fault in the apparatus of the circuit being protected.

instantaneous power—The power at the points where an electric circuit enters a region. It is equal to the rate at which the circuit is transmitting electrical energy into the region.

instantaneous power output—The rate at which energy is delivered to a load at a particular instant.

instantaneous recording—A recording intended for direct reproduction without further processing.

instantaneous sampling—The process of obtaining a sequence of instantaneous values of a wave. These values are called instantaneous samples.

instantaneous sound pressure—The total instantaneous pressure at a certain point, minus the static pressure at that point. The most common unit is the microbar.

instantaneous speech power—The rate at which the speaker is radiating sound energy at any given instant.

instantaneous value—The magnitude, at any particular instant, of a varying value.

instruction—Information which, when properly coded and introduced as a unit into a digital computer, causes the computer to perform one or more of its operations. An instruction commonly includes one or more addresses.

instructional constant — Also called pseudo instruction. In a computer, data stored in the program or instructional area which will be used only as a test constant.

instruction code—The list of symbols, names, and definitions of the instructions which are intelligible to a given computer or computing system.

instruction counter—*See* Control Counter.

instruction modification — A change in the operation-code portion of a computer instruction or command such that, if the routine containing the instruction or command is repeated, the computer will perform a different operation.

instruction register — In a computer, the register that temporarily stores the instruction currently being performed by the control unit of the computer.

instrument—A device capable of measuring, recording, and/or controlling.

instrument approach—A blind landing—i.e., solely by navigational instruments, without visual reference to the terrain.

instrument-approach system — In navigation, a system furnishing vertical and horizontal guidance to aircraft during descent. Touchdown requires some other guidance.

instrumentation—The introduction and use of devices of any kind into a process for the purpose of obtaining more precise data (improving quality) or for obtaining information not otherwise available. Typically accomplished by generating, transmitting, displaying, controlling, correlating, and recording signals.

instrument chopper—A vibrating switch used for modulating, demodulating, and switching d-c or low-frequency a-c information in instrumentation. It is driven synchronously from an a-c or pulsating d-c source. The driven switching circuit is designed for low-level (0- to 10-volt) signal information.

instrument error—The inaccuracy of an instrument.

instrument flight—A blind flight—i.e., one in which the pilot controls the path and altitude of the aircraft solely by instrument.

instrument lamp—A light that illuminates or irradiates an instrument.

instrument-landing station—A special radio station for aiding in landing aircraft.

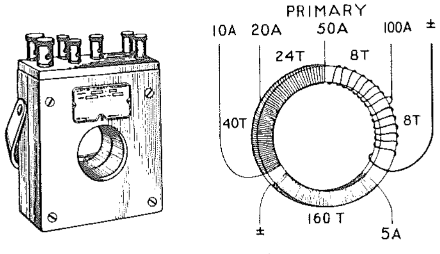
instrument-landing system — Abbreviated ILS. A radionavigation system intended to aid aircraft in landing. It provides lateral and vertical guidance, including distance from the landing point.

instrument multiplier—*See* Voltage-Range Multiplier.

instrument relay—A relay which operates on the principles employed in such electrical measuring instruments as the electrodynamometer, iron-vane, and D'Arsonval meters.

instrument shunt—An internal or external resistor connected in parallel with the circuit of an instrument to extend its current range.

instrument switch—A switch disconnecting an instrument or transferring it from one circuit or phase to another.



Instrument transformers.

instrument transformer — A transformer which reproduces, in its secondary circuit, the primary current (or voltage) with its phase relationship substantially preserved, suitable for utilization in measurement, control, or protective devices.

instrument-transformer correction factor —The factor by which a wattmeter reading must be multiplied to correct for the effect of the instrument-transformer ratio correction factor and phase angle.

insulated—Separated from other conducting surfaces by a nonconductive material offering a high, permanent resistance to the passage of current and disruptive discharge.

insulated carbon resistor—A carbon resistor encased in fiber, plastic, or other insulation.

insulated clip—A clip terminating in an insulated eye through which flexible cords or wires may be run and supported.

insulated enclosure—A special shielded enclosure design providing insulation against weather or providing maximum temperature stability. Usually prefabricated as an exterior building panel in modular construction.

insulated-substrate monolithic circuit—An intergrated circuit which may be either an all-diffused device or a compatible structure so constructed that the components within the silicon substrate are insulated from one another by a layer of silicon dioxide, instead of the reverse-biased PN junctions used for isolation in other techniques.

insulated wire—A conductor covered with a nonconductive material.

insulating material — A material on or through which essentially no current will flow. It is used to confine the flow of current within a conductor or to eliminate the shock hazard of a bare conductor.

insulating tape — Tape that is wrapped around joints in insulated wires or cables. It is impregnated with an insulating material and covered with adhesive on one side.

insulating varnish—A varnish applied to coils and windings to improve their insulation (and, at times, their mechanical rigidity).

insulation—A nonconductive material that prevents the leakage of electricity from a conductor, provides mechanical spacing or support, or protects against accidental contact.

insulation rating — The dielectric-strength and insulation-resistance values required to ensure satisfactory performance.

insulation resistance—1. The ratio of the voltage applied between two electrodes in contact with a specific insulator to the total current between the electrodes. 2. The ratio of the direct-current voltage applied to the terminals of a capacitor and the resulting leakage current after the initial charging current has ceased. It includes both the volume and surface resistance. Industrial specifications usually call for a certain minimum value (several thousand megohms) determined with a specific voltage applied.

insulation system—All of the insulation materials used to insulate a particular electrical or electronic product.

insulator—1. A material of such extremely low conductivity that, in effect, no current flows through it. 2. A high-resistance device that supports or separates conductors to prevent a flow of current between them or to other objects.

insulator arcing ring—A circular or oval metal part placed at one or both ends of an insulator to prevent current from arcing over and damaging it and/or the conductor.

insulator arc-over—The flow of power current over an insulator in the form of an arc following a surface discharge.

insulazing—*See* Surface Insulation.

insulectrics — The science encompassing insulating materials in electrical insulation.

integer—A whole number, not fractional or mixed (e.g., 1, 2, 9, 100, etc.—not 1.1 or ½).

integral-cavity, reflex-klystron oscillator—A reflex-klystron oscillator in which tuning is accomplished by changing the physical dimensions of the resonant cavity. It is usually referred to as a diaphragm- or grid-gap-tuned klystron, since a flexible diaphragm is used to change the cavity dimension, i.e., the gap between the cavity grids.

integral circuit packages—Microcircuits assembled from discrete components and all circuits created essentially in an active or passive substrate.

integral-external-cavity reflex oscillator—A reflex-klystron oscillator in which a fixed internal cavity is tightly coupled to a permanently attached external cavity. Tuning is achieved by varying a reactance probe in the external cavity.

integral-horsepower motor—A motor which is built into a frame and has a continuous rating of one horsepower.

integral resistor—An internal or external resistor preconnected to the electrical element and forming an integral part of the cup assembly to provide a desired electrical characteristic of a precision potentiometer.

integrated amplifier—An audio unit containing both a preamplifier and a power amplifier on one chassis.

integrated circuit—A combination of interconnected circuit elements inseparably associated on or within a continuous substrate. (*Also see* Monolithic Integrated Circuit, Multichip Integrated Circuit, Film Integrated Circuit *and* Hybrid Integrated Circuit.) To further define the nature of an integrated circuit, additional modifiers may be prefixed. Examples are: dielectric isolated monolithic integrated circuit, beam-lead monolithic integrated circuit, or silicon chip-tantalum thin-film hybrid integrated circuit.

integrated-circuit array—Multiple integrated circuits formed on a common substrate and electrically interconnected during fabrication.

integrated component—A number of electrical elements comprising a single structure which cannot be divided without destroying its stated electronic function.

integrated data processing—A method of transforming disjointed and repetitive paperwork tasks into a correlated and mechanized production of information for any purpose.

integrated electronics—That portion of electronic art and technology in which the interdependence of material, device, circuit, and system-design considerations is especially significant; more specifically, that portion of the art dealing with integrated circuits.

integrated equipment components—Integrated-circuit chips which contain a complete logic function. Abbreviated IEC's.

integrated morphology—The structural characterization of an electronic component in which the identity of the current or signal modifying areas, patterns, or volumes has become lost in the integration of electronic materials, in contrast to an assembly of devices performing the same function.

integrating circuit—*See* Integrator.

integrating meter—A meter which adds up (integrates) the electrical energy used over a period of time. An ordinary electric watt-hour meter is an example.

integrating photometer—A photometer which, with a single reading, indicates the average candlepower from a source in all directions or at all angles in a single plane.

integrating relay—A relay that sums up the inputs of voltage or current supplied to it and opens or closes its contacts in response to the input so integrated.

integrating-sphere densitometer—A photoelectric instrument that measures the density of motion-picture film or its sound track.

integrator (in electronic computers)—1. A device with an output proportionate to the integral of the input signal. 2. In certain digital machines, a device that numerically approximates the mathematical process of integration. 3. Also called an integrating network or circuit. A transducer with an output waveform that is the time integral of its input waveform.

intelligence bandwidth—The total audio (or video)frequency bandwidths of one or more channels.

intelligence sample—Part of a signal taken as evidence of the quality of the whole.

intelligence signal—Any signal which conveys information (e.g., voice, music, code, or television).

intelligibility—*See* Articulation.

intensifier electrode—Also called post-accelerating electrode. In some types of electrostatic cathode-ray tubes, an electrode which permits additional acceleration of the electron beam after it has been deflected. This electrode permits greater intensity of the trace without materially reducing the deflection sensitivity of the tube.

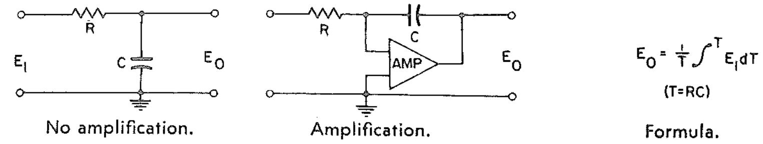
intensifying screen—A thin fluorescent screen placed next to a photographic plate to increase the effect of radiation on the plate.

intensitometer—Also called a dosage meter or dosimeter. An instrument that estimates the amount of X-ray radiation, for determining the duration of exposure during X-ray pictures or therapy.

intensity—1. The strength of a quantity. 2. The relative strength, or amplitude, of electric, magnetic, or vibrational energy. 3. The brilliance of an image on the screen of a cathode-ray tube.

intensity control—Used with cathode-ray tubes to control the intensity of the electron beam and hence the amount of light generated by the fluorescent screen. Generally, the grid bias of the tube is regulated.

intensity level—Ratio of the intensity of the sound to a reference intensity of a free plane wave of 1 microwatt per square centimeter under normal conditions. Commonly expressed in decibels.



No amplification. Amplification. Formula.

Integrating circuits.

intensity modulation—The process and/or effect of varying the electron-beam current in a cathode-ray tube, resulting in varying brightness or luminance of the trace. *Also see* Z-Axis Modulation.

intensity of radiation—The radiant energy emitted in a specified direction per unit time, per unit area of surface, per unit solid angle.

interaction—The effects two or more parts, components, etc., have on each other while each is performing a function.

interaction cross talk—Cross talk resulting from mutual coupling between two paths by means of a third path. For example, if a signal on pair 1 is coupled to pair 2, and then coupled from pair 2 to pair 3, where it is measured it is known as interaction cross talk.

interaction loss (of a transducer)—Expressed in decibels, it equals 20 times the logarithm (to the base *10*) of the scalar value of the reciprocal of the interaction factor.

interaction space—In an electronic tube, the region where the electrons interact with an alternating electromagnetic field.

interaxis error—The deviation from 90° perpendicularity of one set of resolver windings when excitation is applied to one of the other windings. For rotor interaxis error one stator winding is excited; for stator interaxis error one rotor winding is excited.

interbase current—In a junction tetrode transistor, the current that flows from one base connection to the other through the base region.

interblock space—*See* Inter-Record Gap.

intercarrier noise suppression—The means of suppressing the noise resulting from increased gain when a high-gain receiver with automatic volume control is tuned between stations. The suppression circuit automatically blocks the audio-frequency output of the receiver when there is no signal at the second detector.

intercarrier sound system—A television receiving system in which use of the picture carrier and the associated sound-channel carrier produces an intermediate frequency equal to the difference between the two carrier frequencies. This intermediate frequency is frequency-modulated in accordance with the sound signal.

intercellular massage—The ultrasonic stimulation of body cells. Sometimes called micromassage.

intercept receiver—Also called search receiver. A specially calibrated receiver which can be tuned over a wide frequency range in order to detect and measure enemy r-f signals.

intercept service—In a telephone system, a service provided to subscribers whereby calls to disconnected stations or dead lines are either routed to an intercept operator for explanation or the calling party receives a distinctive tone signal to indicate that he has made such a call.

intercharacter space—In telegraphy, the space between characters of a word. It is equal to three unit lengths.

intercom—*See* Intercommunication System.

intercommunicating system—Also called intercom. A two-way communication system without a central switchboard, usually limited to a single vehicle, building, or plant area. Stations may or may not be equipped to originate a call, but can answer any call.

interconnecting wire—Wires used for connections between subassemblies, panels, chassis, and remotely mounted devices. Does not necessarily apply to the internal connections of these units.

interconnection—1. Also called tie line. A transmission line connecting two electric systems or networks and permitting energy to be transferred in either direction. Larger interconnections are often called interties, giant ties, or regional interconnections. 2. Also called intraconnection. The physical wiring between components (outside a module), between modules, between units, or between larger portions of a system or systems.

interconnection diagram—Diagram showing the identity of all units in a piece of electronic equipment and the connections between them.

interconnections (microelectronic)—Those conductors and connections which are not in continuous integral contact with the substrate or circuit elements of an integrated circuit.

interconnection system—The electrical and mechanical interconnection of any one or all of the six levels of interconnections generally common to electronic equipment. The six levels of interconnection are: intramodule, module to motherboard, intramotherboard, motherboard to back panel, back-panel wiring, and input/output.

interdigital magnetron—A magnetron with anode segments around the cathode. Alternate segments are connected together at one end, and remaining segments at the opposite end.

interelectrode capacitance—The capacitance between certain electrodes of an electron tube.

interelectrode coupling—Capacitive feedback from the plate of a tube to the grid. In triodes, this limits the maximum amplification possible without starting oscillation.

interelectrode leakage—The undesired current which flows between elements not normally connected in any way.

interelectrode transit time—The time required for an electron to travel between two electrodes.

interelement capacitance—The capacitance caused by the PN junctions between the regions of a transistor and measured between the external leads of the transistor.

interexchange channel—A channel connecting two different exchange areas.

interface—The junction or the points within or between systems or subsystems where matching or accommodation must be properly achieved in order to make their operation compatible with the successful operation of all other functional entities.

interface resistance—*See* Cathode Interface.

interfacial connection—In a printed-circuit board, a conductor that connects conductive patterns on opposite faces of the base.

interference — Any electrical or electromagnetic disturbance, phenomenon, signal, or emission, man-made or natural, which causes or can cause undesired response, malfunctioning, or degradation of the electrical performance of electrical and electronic equipment.

interference eliminator—A device designed for the purpose of reducing or eliminating interference.

interference fading — Fading produced by different wave components traveling slightly different paths in arriving at the receiver.

interference filter—A device added between a source of man-made interference and a radio receiver to attenuate or eliminate noise signals. It generally contains a combination of capacitance and inductance.

interference guard band—*See* Guard Band.

interference pattern—1. The resultant space distribution of pressure, particle velocity, or energy flux when progressive waves of the same frequency and kind are superimposed. 2. The pattern produced on a radar scope by interference signals.

interference-rejection unit — A tunable filter or wave trap capable of being adjusted to reject any frequency within the i-f passband of a receiver while allowing the remainder of the passband curve to remain intact. It is adjusted to reject an interference signal and thus constitutes a form of antijamming. Abbreviated IFRU.

interference spectrum—The frequency distribution of the jamming interference.

interferometer—An apparatus that shows interference between two or more wave trains coming from the same luminous area, and also compares wavelengths with observable displacements of reflectors or other parts.

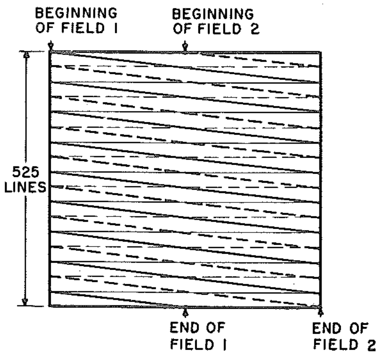
interferometer homing—A homing guidance system in which the direction of the target is determined by comparing the phase of the echo signal as received at more than one antenna.

interior label—In a computer, a magnetically recorded sequence added to a tape to identify the contents.

interior-wiring-system ground—The ground connection to one of the current-carrying conductors of an interior wiring system.

interlace—1. In a computer, to assign successive storage location numbers to physically separated storage locations on a magnetic drum. This serves to reduce access time. 2. To transmit different interrogation modes on successive sweeps.

interlaced scanning—Also called line interlace. A system of scanning whereby the odd- and even-numbered lines of a picture are transmitted consecutively as two separate fields. These are superimposed to create one frame, or complete picture, at the receiver. The effect is to double the apparent number of pictures and thus reduce flicker.



Interlaced scanning.

interlace factor—A measure of the degree of interlace of normally interlaced fields.

interlacing—A method of scanning used in television, in which each picture is divided into two or more complete sets of interlacing lines to reduce flicker.

interleave — 1. In a computer, to insert segments of one program into another program so that the two programs can be executed essentially simultaneously. 2. *See* interlace.

interleaving—Placing between. For example, in the transmission of a composite color signal, the bands of energy of the chrominance signal are interleaved with, or placed between, those of the luminance signal.

interlock—A device actuated by the operation of some other device with which it is directly associated, to govern succeeding operations of the same or allied devices. Interlocks may be either electrical or mechanical.

interlocking—The forcing of a voltage of one frequency to be in step with a voltage of another frequency.

interlock relay—1. A relay in which one armature cannot move or its coil be energized unless the other armature is in a certain position. 2. *See* Checking Relay.

intermediate frequency—Abbreviated if. A frequency to which a signal wave is shifted locally as an intermediate step in transmission or reception.

intermediate-frequency amplifier—1. An amplifier tuned to a fixed frequency, or capable of single-control tuning over a range of frequencies, for the purpose of selecting one of the frequency components generated in a mixer circuit. 2. The section of a superheterodyne receiver which amplifies signals with high efficiency at a predetermined frequency called the intermediate frequency of the receiver.

intermediate-frequency harmonic interference—Interference caused in superheterodyne receivers by the radio-frequency circuit accepting harmonics of the intermediate-frequency signal.

intermediate-frequency interference ratio — *See* Intermediate-Frequency Response Ratio.

intermediate-frequency response ratio — Also called intermediate-frequency interference ratio. In a heterodyne receiver, the ratio of intermediate-frequency signal input at the antenna to the desired signal input for identical outputs.

intermediate-frequency strip—A subassembly containing the intermediate-frequency stages in a receiver.

intermediate-frequency transformer — A transformer designed for use in the intermediate-frequency amplifier of a superheterodyne receiver.

intermediate-frequency-transformer-lead color code — Transformer leads in many radio receivers are identified by the following standard EIA colors:

Blue—plate. Green—grid or diode.
Red—B+. Black—grid return.
Green-black—second diode (full-wave transformers only).

intermediate means—All system elements needed to perform distinct operations in the measurement sequence between the primary detector and the end device.

intermediate-range ballistic missile — A tactical missile or rocket weapon with a range of 200 to 1,500 miles.

intermediate repeater — A repeater used other than at the end of a trunk or line.

intermediate state—The partial superconductivity that occurs when a magnetic field of appropriate strength is applied to a sphere of material below its critical temperature (i.e., the temperature below which the material superconducts if no magnetic field were present).

intermediate subcarrier—A carrier used for modulating a carrier or another intermediate subcarrier. It also may have been modulated by one or more subcarriers.

intermediate switching region—In a relay, an area between low level (including dry circuit) and power switching (including full rated load) where the contact arc does not destroy deposits which are by-products of the switching function.

intermittent—Occurring at intervals.

intermittent current—A unidirectional current that is interrupted at intervals.

intermittent defect—A defect that depends on variable conditions in a circuit. Hence it is not present at all times.

intermittent duty—Operation for specified alternate intervals of load and no-load; load and rest; or load, no-load, and rest.

intermittent-duty rating—The output rating of a device operated for specified intervals, rather than continuously.

intermittent-duty relay — A relay which must be de-energized at intervals to avoid excessive temperature, or a relay that is energized at regular or irregular intervals, as in pulsing.

intermittent pulsing — The transmission of short bursts of radiation at irregular intervals.

intermittent reception—A defect where the receiver operates normally for a while, at regular or irregular intervals.

intermittent scanning—One or two 360° scans of an antenna beam at irregular intervals to make detection by intercept receivers more difficult.

intermittent-service area—An area still receiving the ground wave of a broadcast station, but subject to interference and fading.

intermodulation—1. In a nonlinear transducer element, the production of frequencies corresponding to the sums and differences of the fundamentals and harmonics of two or more frequencies transmitted through the transducer. 2. An error form that occurs in chopper-stabilized amplifiers when a beat component forms between the chopper drive frequency and normal signals which have frequencies near that of the chopper.

intermodulation distortion — Nonlinearity characterized by the appearance of frequencies in the output equal to the sums and differences of integral multiples of the component frequencies present in the input signal. (Harmonics are usually not included.)

intermodulation frequencies—The sum and difference frequencies generated in a nonlinear element.

intermodulation interference—The combination-frequency tones produced at the output by a nonlinear amplifier or network when two or more sinusoidal voltages are applied at the input. Generally expressed as the ratio of the root-mean-square voltage of one or more combination frequencies to that of one of the parent frequencies measured at the output.

intermodulation noise—Noise introduced in the channel of interest by signals being transmitted in other channels.

internal arithmetic—Any computations performed by the arithmetic unit of a computer, as distinguished from those performed by peripheral equipment.

internal calibration—Calibration by an internal voltage source (provided with the instrument) rather than an external standard.

internal connection—Abbreviated IC. In a vacuum tube, a base-pin connection designed not to be used for any circuit connections.

internal correction voltage — The voltage added to the composite controlling voltage of an electron tube. It is the voltage equivalent of those effects produced by initial electron velocity, contact potential, etc.

internal graticule—A graticule the rulings of which are a permanent part of the inner surface of the cathode-ray tube faceplate.

internal input impedance—The actual impedance at the input terminals of a device.

internally caused contact chatter — That chatter resulting from the operation or release of the relay. It may be classified as initial, armature-impact, armature-rebound, or armature-hesitation chatter.

internally stored program — A sequence of instructions (program) stored inside a computer in the same storage facilities as the computer data, as opposed to being stored externally on punched paper tape, pin boards, etc.

internal magnetic recording—Storage of information within the material itself, such as used in magnetic cores.

internal memory—Also called internal storage. The total memory or storage which is automatically accessible to a computer. It is an integral physical part of the computer and is directly controlled by it.

internal output impedance—The actual impedance at the output terminals of a device.

internal resistance—The inherent resistance of a battery, generator, or circuit component.

internal storage — 1. Storage facilities in a computer forming an integral physical part of and directly controlled by the computer. 2. The total storage automatically available to the computer.

international broadcast station—A station licensed for transmission of broadcast programs for international public reception. By international agreement, frequencies are allocated between 6,000 and 26,600 kHz.

international call sign—The identifying letters and numbers assigned to a radio station in accordance with the International Telecommunications Union. The first character, or the first two, identify the nationality of the station.

international communication service — A telecommunication service between offices or stations (including mobile) belonging to different countries.

international coulomb — The quantity of electricity passing any section of an electric circuit in one second when the current is one international ampere. One international coulomb equals 0.99985 absolute coulomb.

international farad—The capacitance of a capacitor when a charge of one international coulomb produces a potential difference of one international volt between the terminals. One international farad equals 0.99952 absolute farad.

international henry—The inductance which produces an electromotive force of one international volt when the current is changing at a rate of one international ampere per second. One international henry equals 1.00018 absolute henrys.

international joule—The energy required to transfer one international coulomb between two points having a potential difference of one international volt. One international joule equals 1.00018 absolute joules.

International Morse code—Also called Continental code. A system of dot-and-dash signals used chiefly for international radio and wire telegraphy. It differs from American Morse code in certain code combinations only.

international ohm—The resistance at 0°C. of a column of mercury of uniform cross section 106.300 centimeters in length and with a mass of 14.4521 grams. One international ohm equals 1.00048 absolute ohms.

International Radio Consultative Committee — Abbreviated CCIR. An international committee which studies technical operating and tariff questions pertaining to radio, broadcast television, and multichannel video transmissions and issues recommendations. It reports to the International Telecommunications Union.

international radio silence — Three-minute periods of radio silence, commencing 15 and 45 minutes after each hour, on a frequency of 500 kHz only. During this time all radio stations are supposed to listen on that frequency for distress signals of ships and aircraft.

international radium standard—A standard of radioactivity, consisting of 21.99 milligrams of pure radium chloride.

international system (of electrical and magnetic units)—A system for measuring electrical and magnetic quantities by using four fundamental quantities. Resistance and current are arbitrary values that correspond approximately to the absolute ohm and the absolute ampere. Length and time are arbitrarily called centimeter and second. The international system of electrical units was used between 1893 and 1947. By international agreement, it was discarded on January 1, 1948, in favor of the mksa (Giorgi) system.

International Telecommunications Union—The international counterpart of the Federal Communications Commission. It provides standardized communications procedures and practices, including frequency allocations and radio regulations, on a world-wide basis.

International Telegraph Consultative Committee — Abbreviated CCIT. An international committee responsible for studying technical operating and tariff questions pertaining to telegraph and facsimile and issuing recommendations. It reports to the International Telecommunications Union.

International Telephone Consultative Committee — Abbreviated CCIF. An international committee responsible for studying and issuing recommendations regarding technical operations and tariff questions pertaining to ordinary telephones; carrier telephones; and music, picture, television, and multichannel telegraph transmission over wire line. It reports to the International Telecommunications Union.

international temperature scale — A temperature scale adopted in 1948 by international agreement. Between the boiling point of oxygen (−182.97°C) and 630.5°C it is based upon the platinum resistance thermometer. From 630.5°C to 1063.0°C it is based on the platinum rhodium thermocouple, and above 1063.0°C on the optical pyrometer.

international volt—The voltage that will produce a current of one international ampere through a resistance of one international ohm. One international volt equals 1.00033 absolute volts.

international watt—The power expended when one international ampere flows between two points having a potential difference of one international volt. One international watt equals 1.00018 absolute watts.

interphase transformer — An autotransformer or a set of mutually coupled reactors used with three-phase rectifier transformers to modify current relationships in the rectifier system and thereby cause a greater number of rectifier tubes to carry current at any instant.

interphone system—An intercommunication system like that in an aircraft or other mobile unit.

interpolation—The process of finding a value between two known values on a chart or graph.

interpole—A small auxiliary pole placed between the main poles of a direct-current generator or motor to reduce sparking at the commutator.

interpreter — A punch-card machine which will read the information conveyed by holes punched in a card and print its translation in characters arranged in specified rows and columns on the card.

interpreter code — A computer code which an interpretive routine can use.

interpretive programming — The writing of computer programs in a "pretend" machine language, which the computer precisely converts into actual machine-language instructions before performing them.

interpretive routine—Computer routine designed to transfer each pseudocode and, using function digits, to set a branch order that links the appropriate subroutine into the main program.

interrecord gap — Also called interblock space. The space between records on magnetic tape caused by delays involved in starting and stopping the tape motion. This gap is used to signal that the end of a record has been reached.

interrogation—The triggering of one or more transponders by transmitting a radio signal or combination of signals.

interrogation signal—A pulsed or c-w signal emitted to initiate a reply signal from a transponder or responder.

interrogator—Also called challenger. A radio transmitter used to trigger a transponder.

interrogator-responser—A combined radio transmitter and receiver for interrogating a transponder and displaying the replies.

interrupt—In a computer, a break in the normal flow of a system or routine such that the flow can be resumed from that point at a later time. An interrupt is usually caused by a signal from an external source.

interrupted continuous waves—Continuous waves that are interrupted at an audio-frequency rate.

interrupter—A magnetically operated device used for rapidly and periodically opening and closing an electric circuit in doorbells and buzzers and in the primary circuit of a transformers supplied from a d-c source.

interrupter contacts — On a stepping relay, an additional set of contacts operated directly by the armature.

interrupting capacity—The highest current at which the device can interrupt at the rated voltage.

interrupting rating — Conditions under which the contact of a relay must interrupt with a prescribed duty cycle and contact life.

interrupting time—In a circuit breaker, the interval between the energizing of the trip coil and the interruption of the circuit, at the rated voltage.

interstage—Between stages.

interstage coupling — Coupling between stages.

interstage punching — A system in which only the odd-numbered rows are punched in the British standard card.

interstage transformer—A transformer that couples two stages together.

interstation noise suppression—Canceling of the noise which occurs when a high-gain radio receiver with automatic volume control is tuned between stations.

interties—*See* Interconnection.

interval calibration—*See* Step Calibration.

interval circuit—A circuit which is energized during timing only. This can be accomplished by using a timer with interval contacts; or by using a timer with delayed contacts in series with the start switch, or one with instantaneous contacts in series with delayed contacts.

interval contacts—In a timer, contacts which are actuated only for the duration of the present time interval.

interval timer—1. A device for measuring the time interval between two actions. 2. A timer which switches electrical circuits on or off for the duration of the preset time interval.

interword space—In telegraphy, the space between words or coded groups. It is equal to seven unit lengths.

intonation—The slight modification of pitch, or frequency, that makes a note sound flat or sharp compared with the natural frequency of the note played.

intraconnections (microelectronics)—Those conductors and connections which are in continuous integral contact with the substrate or circuit elements of an integrated circuit.

intrinsic-barrier diode—A PIN diode in which a thin region of intrinsic material separates the N-type and P-type region.

intrinsic-barrier transistor—A PNIP or NPIN transistor in which a thin region of intrinsic material separates the collector from the base.

intrinsic brightness—The luminous intensity measured in a given direction per unit of apparent (projected) area when viewed from that direction.

intrinsic coercive force—The magnetizing force that, when applied to a magnetic material in a direction opposite to that of the residual induction, reduces the intrinsic induction to zero.

intrinsic coercivity—The measurement (in oersteds) of the force required to reduce the intrinsic induction of the magnetized material to zero.

intrinsic concentration—In a semiconductor, the number of minority carriers that exceeds the normal equilibrium number.

intrinsic conduction—In an intrinsic semiconductor, the conduction associated with the directed movement of electron-hole pairs under the influence of an electric field.

intrinsic-contact potential difference—The true potential difference between two spotlessly clean metals in contact.

intrinsic electric strength—The characteristic electric strength of a material.

intrinsic induction—The excess magnetic induction produced in a magnetic material by a given magnetizing force, over the induction that would be produced by the same magnetizing force in a vacuum.

intrinsic-junction transistor—*See* Intrinsic-Region Transistor.

intrinsic layering—The method of separating two conductive semiconductor regions by a region of near-intrinsic semiconductor material.

intrinsic mobility—The mobility of electrons in an intrinsic semiconductor, or in a semiconductor having a very low concentration of impurities.

intrinsic noise—Noise that is due to the device or transmission path and is independent of modulation.

intrinsic permeability—Ratio of intrinsic normal induction to the corresponding magnetizing force.

intrinsic properties—The semiconductor properties which are characteristic of the pure, ideal crystal.

intrinsic Q—*See* Unloaded Q.

intrinsic region—*See* Depletion Region.

intrinsic-region transistor—Also called intrinsic-junction transistor. A four-layer transistor with an intrinsic region between the base and collector. Examples are NPIN, PNIP, NPIP, and PNIN transistors.

intrinsic semiconductor—1. A semiconductor in which some hole and electron pairs are created by thermal energy at room temperature, even though there are no impurities in it. 2. A semiconductor with substantially the same electrical properties as those of the ideal crystal.

intrinsic temperature range—The temperature range at which impurities or imperfections within the crystal do not modify the electrical properties of a semiconductor.

Invar—An alloy containing 63.8% iron, 36% nickel, and 0.2% carbon. Has a very low thermal coefficient of expansion. Used primarily as resistance wire in wirewound resistors.

inverse electrical characteristics—In a transistor, those characteristics obtained when the collector and emitter terminals are interchanged and the transistor is then tested in the normal manner.

inverse electrode current—The current flowing through an electrode in the opposite direction from that for which the tube was designed.

inverse feedback—Returning part of the output power of an amplifying device to its input circuit in order to cancel a portion of the input.

inverse-feedback filter—A tuned circuit at the output of a highly selective amplifier having negative feedback. The feedback output is zero for the resonant frequency, but increases rapidly as the frequency deviates.

inverse limiter—A transducer with a constant output for inputs of instantaneous values within a specified range. Above and below that range, the output is linear or some other prescribed function of the input.

inverse networks—Any two two-terminal networks in which the product of their impedances is independent of frequency within the range of interest.

inverse-parallel connection—*See* Back-to-Back Circuit.

inverse peak voltage—1. The peak instantaneous voltage across a rectifier tube during the nonconducting half-cycle. 2. The highest negative voltage reached between the plate and cathode of a rectifier tube.

inverse photoelectric effect—The transformation of the kinetic energy of a moving electron into radiant energy, as in the production of X-rays.

inverse piezoelectric effect—Contraction or expansion of a piezoelectric crystal under the influence of an electric field.

inverse ratio—The seesaw effect whereby one value increases as the other decreases or vice versa.

inverse-square law—The strength of a field, or the intensity of radiation, decreases in proportion to the square of the distance from its source.

inverse time—A qualifying term applied to a relay, indicating that its time of operation decreases as the magnitude of the operating quantity increases.

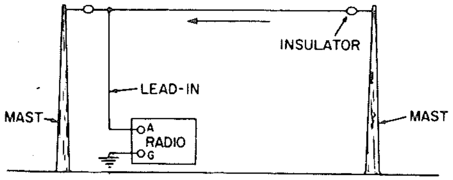
inverse voltage—The effective voltage across a rectifier tube during the half-cycle when current does not flow.

inverse Wiedeman effect—*See* Wiedeman Effect.

inversion—1. The bending of a radio wave because the upper part of the beam is slowed down as it travels through denser air. This may occur when a body of cold air moves in under a moisture-laden body of air. 2. The producing of inverted or scrambled speech by beating an audio-frequency signal with a fixed band of the resultant beat frequencies. The original low audio frequencies then become high frequencies and vice versa.

inverted amplifier—An amplifier stage containing two vacuum tubes. The control grids are grounded, and the driving excitation is applied between the cathodes. The grids then serve as a shield between the input and output circuits. Thus, the output-circuit capacitance is greatly reduced.

inverted-L antenna—An antenna consisting of one or more horizontal wires with a vertical wire connected at one end.



Inverted-L antenna.

inverted speech—*See* Scrambled Speech.

inverter—1. A circuit which takes in a positive signal and puts out a negative one, or vice versa. 2. A device that changes alternating current to direct current or vice versa. It frequently is used to change 6-volt or 12-volt direct current to 110-volt alternating current. 3. A device that accepts an input that is a function of the maximum voltage and changes it into an output that is a function of both the maximum voltage and time. 4. A circuit with one input and one output, and its function is to invert the input. When the input is high, the output is low, and vice versa. The inverter is sometimes called a NOT circuit, since it produces the reverse of the input.

inverting connection—The closed-loop connection of an operational amplifier when the forward gain is negative for d-c signals. A 180° phase shift.

inverting parametric device—A parametric device the operation of which depends essentially upon three frequencies—a harmonic of the pump frequency, and two signal frequencies—of which the higher signal frequency is the difference between the pump harmonic and the lower signal frequency.

I/O device—Abbreviation for input/output device. A card reader, magnetic tape unit, printer, or similar device that transmits data to or receives data from a computer or secondary storage device.

ion—An electrically charged atom or group of atoms. Positively charged ions have a deficiency of electrons, and negatively charged ions have surplus electrons.

ion charging—In a storage tube, spurious charging or discharging caused by ions striking the storage surface.

ion counter—A tubular chamber for measuring the ionization of air.

ionic focusing—Focusing the electron beam in a cathode-ray tube by varying the filament voltage and temperature to change the electrostatic focusing field automatically produced by the accumulation of positive ions in the tube.

ionic-heated cathode—A cathode that is heated primarily by bombardment with ions.

ionic-heated cathode tube—An electron tube containing an ionic-heated cathode.

ionization—1. A process by which electrons are detached from atoms or molecules, thus originating ions and free electrons. It can be done by high-energy radiation or by collisions. 2. The electrically charged particles produced by high-energy radiation (such as light or ultra-violet rays) or by the collision of particles during thermal agitation.

ionization chamber—An enclosure containing two or more electrodes between which an electric current may pass when the gas within is ionized. The current is a measure of the total number of ions produced in the gas by externally induced radiations.

ionization current—The current resulting from the movement of electric charges, under the influence of an applied electric field, in an ionized medium.

ionization energy—Sometimes called ionization potential. The minimum amount of energy (usually expressed in electron-volts) required to eject an electron from a molecule.

ionization gage—A gage that measures the degree of a vacuum in an electron tube by the amount of ionization current in the tube.

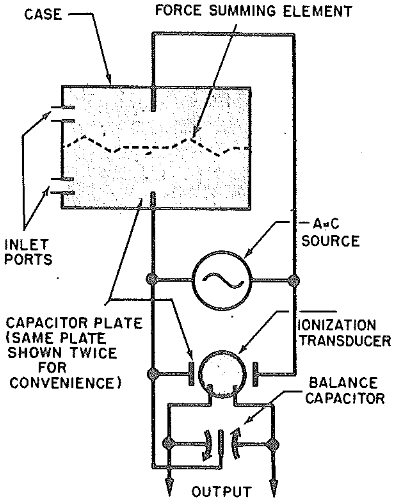
ionization-gage tube—An electron tube that measures low gas pressure by the amount of ionization current produced.

ionization potential—Also called critical potential. The minimum energy that will produce ionization in a substance. Expressed as volts acting on one electronic charge.

ionization pressure—An increase in the pressure in a gaseous discharge tube due to ionization of the gas.

ionization resistance — *See* Corona Resistance.

ionization time—The time interval between the initiation and the establishment of conduction in a gas tube at some stated voltage drop for the tube.



Ionization transducer.

ionization transducer — A transducer in which displacement of the force-summing member is sensed by the induced changes in differential ion conductivity.

ionization vacuum gage—A gage in which the operation depends on the positive ions produced in a gas by electrons as they accelerate between a hot cathode and another electrode in a vacuum. It ordinarily covers a pressure range of 10^{-4} to 10^{-10} mm of mercury.

ionize—To free an electron from an atom or molecule (e.g., by X-ray bombardment) and thus transform the atom or molecule into a positive ion. The freed electron attaches itself to another atom or molecule, which then becomes a negative ion.

ionized layers—Layers of increased ionization within the ionosphere. They are responsible for absorption and reflection of radio waves and are important for communication and for tracking satellites and other space vehicles.

ionizing event—Any interaction by which one or more ions are produced.

ionizing radiation — Electromagnetic radiation or particle radiation having sufficient energy to dislodge electrons from atoms or molecules, thereby producing ions.

ion migration—Movement of the ions produced in an electrolyte by application of an electric potential between electrodes.

ionophone — A high-frequency speaker in which the audio-frequency signal modulates an r-f supply to maintain an arc in the mouth of a quartz tube. The resultant modulated wave acts directly on the ionized air under pressure and thus creates sound waves.

ionosphere—The part of the earth's outer atmosphere where sufficient ions and electrons are present to affect the propagation of radio waves.

ionospheric disturbance—The variation in the state of ionization of the ionosphere beyond the normal observed random day-to-day variation from average value for the location, data, and time of day under consideration.

ionospheric error—Also called sky error. In navigation, the total systematic and random error resulting from reception of the navigational signal after it has been reflected from the ionosphere. It may be due to variations in the transmission path, uneven height of the ionosphere, or uneven propagation within the ionosphere.

ionospheric prediction—The forecasting of ionospheric conditions and the preparation of radio propagation data derived from it.

ionospheric scatter—*See* Forward Scatter.

ionospheric storm—An ionospheric disturbance associated with abnormal solar activity and characterized by wide variations from normal, including turbulence in the F-region and increases in absorption. Often the ionization density is decreased and the virtual height is increased. The effects are most marked in high magnetic latitudes.

ionospheric wave—Also called a sky wave. A radio wave that is propagated by way of the ionosphere.

ion sheath—A positive-ion film which forms on or near the grid of a gas tube and limits its control action.

ion spot—1. In camera or image tubes, the spurious signal resulting from bombardment of the target or photocathode by ions. 2. On a cathode-ray-tube screen, an area where the luminescence has been deteriorated by prolonged bombardment with negative ions.

ion trap—Also called a beam bender. An electron-gun structure and magnetic field which diverts negative ions to prevent their burning a spot in the screen, but permits electrons to flow toward the screen.

I_p—Symbol for the plate current of a vacuum tube.

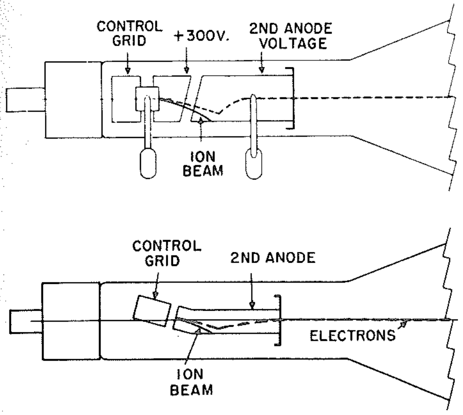
I-phase carrier—Also called in-phase carrier. A carrier separated in phase by 57° from the color subcarrier.

ips—Abbreviation for inches per second.

IR—Abbreviation for interrogator-responser or infrared.

I^2R—Power in watts expressed in terms of the current (I) and resistance (R).

IRAC—Acronym for Interdepartmental Radio Advisory Committee. It is composed of representatives of eleven government agencies: The FCC; Army; Navy; Air Force; Maritime Commission; and the Treasury, State, Commerce, Agriculture, Interior, and Justice Departments.



Ion trap.

IR compensation — A control device that compensates for voltage drop due to current flow.

IR drop—The voltage drop produced across a resistance (R) by the flow of current (I) through it.

IRE—Abbreviation for Institute of Radio Engineers, an organization now merged with AIEE. *See* IEEE.

i (intrinsic) region — In silicon, a pure region of the group-IV element (i.e., having neither excess holes or excess electrons, and therefore having very high resistivity).

iris—Also called diaphragm. In a waveguide, a conducting plate which is very thin (compared with the wavelength) and occupies part of the cross section of a waveguide.

I^2R loss—The power lost in transformers, generators, connecting wires, and other parts of a circuit because of the current flow I through the resistance R of the conductors.

iron-constantan — A combination of metals used in thermocouples, thermocouple wires, and thermocouple lead wires. Constantan is an alloy of copper, nickel, manganese, and iron.

iron-core coil—A coil in which iron forms part or all of the magnetic circuit, linking its winding. In a choke coil, the core is usually built up of laminations of sheet iron.

iron-core transformer — A transformer in which iron forms part or all of the magnetic circuit, linking the transformer windings.

iron loss—*See* Core Loss.

iron-vane instrument—A measuring instrument in which the movable element is an iron vane.

irradiation—The application of X-rays, radium rays, or other radiation.

irregularity—A change from normal in the impedance characteristics.

I-scan—A radar display in which a target appears as a complete circle when the radar antenna is correctly pointed at it, the radius of the circle being proportional to the target distance.

I-scope—*See* I-scan.

I-signal—Also called the fine-chrominance primary. A signal formed by the combination of an R—Y signal having a +.74 polarity and a B—Y signal having a —.27 polarity. One of the two signals used to modulate the chrominance subcarrier, the other being the Q signal.

ISM equipment—A Federal Communications Commission designation for *i*ndustrial, *s*cientific, and *m*edical equipment capable of causing interference.

isobar—1. On meteorological maps, a line denoting places having the same atmospheric pressure at a given time. 2. One of a group of atoms or elements having the same atomic weights but different atomic numbers.

isochrone—On a map or chart, a line joining points associated with a constant time difference in the reception of radio signals.

isochrone determination—A radio location in which a position line is determined by the difference in transit times of signals along two paths.

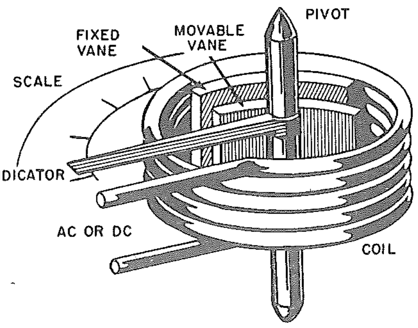
isochronous circuits — Circuits having the same resonant frequency.

isoclinic line—*See* Aclinic Line.

isodynamic lines—On a magnetic map, lines passing through points of equal strength of the earth's magnetic field.

isoelectronic—Having the same number of electrons outside the nucleus of the atom.

isolated—Utterly cut off from; refers to that condition in which a conductor, circuit, or device is not only insulated from another (or others), but the two are mutually unable to engender current, emf, or magnetic flux in each other. As commonly used, insulation is associated predominantly with direct current, whereas isolation implies additionally a bulwark against a-c fields.



Iron-vane instrument (movable).

isolated amplifier—A differential amplifier in which the input-signal lines are conductively isolated from the output-signal lines and chassis ground.

isolating diode—A diode that passes signals in one direction through a circuit but blocks signals and voltages in the opposite direction.

isolating switch—A switch intended for isolating an electric circuit from the source of power. It has no interrupting rating and is intended to be operated only after the circuit has been opened by some other means.

isolation—1. Electrical or acoustical separation between two locations. 2. The technique for producing a high electrical resistance between an integrated-circuit component and the substrate in which it is formed.

isolation amplifier—An amplifier employed to minimize the effects of the following circuit on the preceding circuit.

isolation network—A network inserted into a circuit or transmission line to prevent interaction between circuits on each side of the insertion point.

isolation transformer — A transformer designed to provide magnetic coupling (flux coupling) between one or more pairs of isolated circuits, without introducing significant coupling of any other kind between them—i.e., without introducing either significant conductive (ohmic) or significant electrostatic (capacitive) coupling.

isolator ferrite—A microwave device which allows r-f energy to pass through in one direction with very little loss but absorbs r-f power in the other direction.

isolith—An integrated circuit of components formed on a single silicon slice, but with the various components interconnected by beam leads and with circuit parts isolated by removal of the silicon between them.

isomer—One of two or more substances composed of molecules having the same kinds of atoms in the same proportions but arranged differently. Hence, the physical and chemical properties are different. Isomers which do not have the same molecular weights are called polymers.

isostatic — Being subjected to equal pressure from every side.

isothermal region—The stratosphere considered as a region of uniform temperature.

isotones — A group of atoms the nuclei of which have the same number of neutrons.

isotope—A species of matter the atoms of which contain the same number of protons as some other species, but a different number of neutrons. The atomic numbers of isotopes are identical, but the mass numbers (atomic weights) differ.

isotropic—Having the same properties in all directions.

isotropic antenna — Also called unipole. A hypothetical antenna radiating or receiving equally in all directions. A pulsating sphere is a unipole for sound waves. In the case of electromagnetic waves, unipoles do not exist physically, but represent convenient reference antennas for expressing directive properties of actual antennas.

isotropic gain of an antenna—*See* Absolute Gain of an Antenna.

isotropic magnet—A magnetic material having no preferred axis of magnetic characteristics.

isotropic radiator—A radiator which sends out equal amounts of energy in all directions.

item—A general term denoting one of a number of similar units, assemblies, objects, etc.

iterative impedance—An impedance used to terminate one of two pairs so that the other pair of terminals will have the same input impedance.

iterative process—The calculating of a desired result by means of a repeating cycle of operations which comes closer and closer to the desired result.

iterative routine—A computer routine composed of repetitive computations, so that the output of every step becomes the input of the succeeding step.

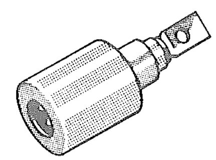
ITU—Abbreviation for International Telecommunications Union, an international organization established to provide standardized communications procedures and practices, including frequency allocation and radio regulations on a world-wide basis. It is the international equivalent of the Federal Communications Commission.

ITV—Abbreviation for industrial television.

I-type—Intrinsic semiconductor.

J

J—Abbreviation for joule.



Jack.

jack—A socket to which, the wires of a circuit are connected at one end, and into which a plug is inserted at the other end.

jacket — Pertaining to wire and cable, the outer sheath of which protects against environment and may also provide additional insulation.

jack panel—An assembly composed of a number of jacks mounted on a board or panel.

jackscrew—A screw attached to one-half of a two-piece, multiple-contact connector and used to draw both halves together and to separate them.

jaff—Slang for the combination of electronic and chaff jamming.

jag—In facsimile, distortion caused in the received copy by a momentary lapse in synchronism between the scanner and recorder.

jam—In punch-card machines, a condition in the card feed which interferes with the normal travel of the punch cards through the machine.

jammer—An electronic device for intentionally introducing unwanted signals into radar sets to render them ineffective.

jammer band — The radio-frequency band where the jammer output is concentrated. It is usually the band between the points where the intensity is 3 db down from maximum.

jammer finder — Also called burnthrough. Radar which attempts to obtain the range of the target by training a highly directional pencil beam on a jamming source.

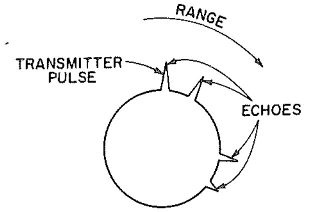
jamming—The intentional transmission of radio signals in order to interfere with the reception of signals from another station.

jamming effectiveness—The jamming-to-signal ratio—i.e., the percentage of information incorrectly received in a test message.

JAN specification — Joint Army-Navy specification. The forerunner of present Military Specifications, which are generally superseded by the designation MIL.

J-antenna—A half-wave antenna fed at one end by a parallel-wire, quarter-wave section having the configuration of a *J*.

J-carrier system—A broad-band carrier system which provides 12 telephone channels and utilizes frequencies up to about 140 kilohertz by means of four-wire transmission on a single open-wire pair.



J-display.

J-display—Also called J-scan. In radar, a modified A-display in which the time base is a circle and the target signal appears as a radial deflection from it.

JEDEC—Acronym for Joint Electron Device Engineering Council.

JETEC — Acronym for Joint Electron Tube Engineering Council.

jewel bearing—A natural or synthetic jewel, usually sapphire, used as a bearing for a pivot or other moving parts of a delicate instrument.

jezebel—A system for the detection and classification of submarines.

jitter—1. Instability of a signal in either its amplitude, its phase, or both. The term is applied especially to signals reproduced on the screen of a cathode-ray tube. The term "tracking jitter" describes minor variations in the pointing of an automatic tracking radar. 2. In facsimile, raggedness in the received copy caused by erroneous displacement of recorded spots in the scanning direction. 3. An aberration of a repetitive display indicating instability of the signal or of the oscilloscope. May be random or periodic, and is usually associated with the time axis. 4. *See* Flicker *and* Fortuitous distortion.

jittered pulse recurrence frequency—The random variation of the pulse-repetition period. Provides a discrimination capability against repeater-type jammers.

jogging—Also called inching. Quick and repeated opening and closing of a motor starting circuit to produce slight movements of the motor.

Johnson noise—Also called thermal noise. The noise generated by any resistor at a temperature above absolute zero. It is proportionate to the absolute temperature and the bandwidth, according to the following formula:

$$N = KTB$$

where,

N is the noise power in watts,
K is Boltzmann's constant, or 1.38047 $\times 10^{-23}$
T is the absolute temperature in degrees Kelvin,
B is the bandwidth in hertz.

joined actuator — A multipole breaker such that when one pole trips, all trip, but whereas the faulted pole is trip-free, the other poles may be kept maintained by a restraining actuator.

joint — A connection between two or more conductors.

joint use—The simultaneous use of pole, line, or plant facilities by two or more kinds of utilities.

Jones plug—A type of polarized connector designed in the form of a receptacle and having several contacts.

Josephson effect — The phenomenon described by Brian Josephson to explain the action of currents through and voltages across hairlike gaps in superconductors. On the basis of theoretical considerations, it is predicted that if two superconductors could be brought close enough together, a current could be made to flow across the gap between them. Under certain conditions, a voltage appears across the gap, and high-frequency radiation emanates from it. This predicted radiation would have a frequency precisely equal to 2eV/h, where V is the measured voltage across the gap.

joule—1. The work done by a force of 1 newton acting through a distance of 1 meter. The joule is the unit of work and energy in the MKSA system. 2. The energy required to transport 1 coulomb between two points having a potential difference of 1 volt. The joule is 10^7 ergs. The kilowatt-hour is 3.6×10^6 joules.

Joule effect—In a circuit, electrical energy is converted into heat by an amount equal to I^2R. Half of this heat flows to the hot junction and the other half to the cold junction.

Joule heat—The thermal energy produced as a result of the Joule effect.

Joule's law of electric heating—The amount of heat produced in a conductor is proportional to the resistance of the conductor, the square of the current, and the time.

J-scan—*See* J-Display.

J-scope—Also called Class-J oscilloscope. A cathode-ray oscilloscope that presents a J-display.

J/S ratio—A ratio, normally expressed in db, of the total interference power to the signal-carrier power in the transmission medium at the receiver.

juice—Slang for electric current.

jump—To cause the next instruction to be selected from a specified storage location in a computer.

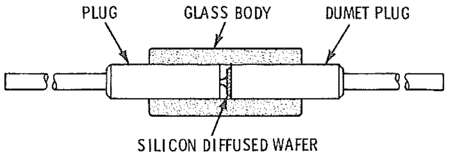
jumper—1. A short length of wire used to complete a circuit temporarily or to bypass a circuit. 2. A direct electrical connection, which is not a portion of the conductive pattern, between two points in a printed circuit.

junction—1. A connection between two or more conductors or two or more sections of a transmission line. 2. A contact between two dissimilar metals or materials (e.g., in a rectifier or thermocouple). 3. A region of transition between P- and N-type semiconductor material. The controllable resultant asymmetrical properties are exploited in semiconductor devices. There are diffused, alloy, grown, and electrochemical junctions.

junction barrier—The opposition to the diffusion of majority carriers across a PN junction due to the charge of the fixed donor and acceptor ions.

junction box—A box for joining different runs of raceway or cable, plus space for connecting and branching the enclosed conductors.

junction diode—A two-terminal device containing a single crystal of semiconducting material which ranges from P-type at one terminal to N-type at the other. It conducts current more easily in one direction than in the other and is a basic element of the junction transistor. When fabricated in a suitable geometrical form, it can be used as a solar cell.



Junction-diode assembly.

junction filter—A combination of a high-pass and a low-pass filter which is used to separate frequency bands for transmission over separate paths. For example, junction filters are used to separate voice and carrier frequencies at the junction between open-wire and cable so that the carrier frequencies and voice frequencies can be sent over nonloaded and v-f loaded cable pairs, respectively.

junction point—*See* Node.

junction station—A microwave relay station that joins a microwave radio leg or legs to the main, or through, route.

junction transistor — A transistor having three alternate sections of P-type or N-type semiconductor material. (*Also see* PNP Transistor *and* NPN Transistor.)

junctor—In crossbar systems, a circuit extending between frames of a switching unit and terminated in a switching device on each frame.

just-operate value — Also called drop-out value. The measured functioning value at which a particular relay releases.

just-release value—The measured functioning value at which a particular relay releases.

just scale—A musical scale formed by three consecutive triads (those in which the highest note of one is the lowest note of the other), each having the ratio 4:5:6 or 10:12:15.

jute—Cordage fiber (such as hemp) saturated with tar and used as a protective layer over cable.

jute-protected cable — A cable having its sheath covered by a wrapping of tarred jute or other fiber.

K

k—Abbreviation for kilo.

K—1. Symbol for cathode or dielectric constant. 2. Abbreviation for Kelvin or kilo. 3. Abbreviation for luminosity factor.

ka—Abbreviation for kiloampere.

Karnaugh map—A truth table that is rearranged to show a geometrical pattern of functional relationships for gating configurations. Essential gating requirements can then be recognized in their simplest form.

K-band—A radio frequency band extending from 11 to 36 GHz and having wavelengths of 2.73 to 0.83 cm.

kc—Abbreviation for kilocycle. Now obsolete.

K-carrier system—A broad-band carrier system which provides 12 telephone channels and utilizes frequencies up to about 60 kHz by means of four-wire transmission on cable facilities.

K-display—Also called K-scan. Modification of a type-A scan, used for aiming a double-lobe system in bearing or elevation. The entire range scale is displaced toward the antenna lobe in use. One signal appears as a double deflection from the range and relative scales. The relative amplitudes of these two pips indicate the amount of error in aiming the antenna.

keep-alive anode — An auxiliary electrode that maintains a d-c discharge in a mercury-pool tube. It has the disadvantage of reducing the peak inverse voltage rating.

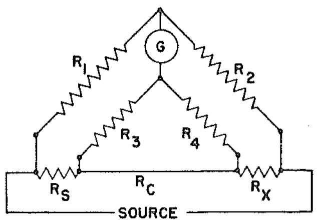
keep-alive circuit — In a TR or anti-TR switch, a circuit for producing residual ionization in order to reduce the time for full ionization when the transmitter fires.

keep-alive voltage—A d-c voltage that maintains a small glow discharge within one of the gap electrodes of a TR tube. This allows the tube to ionize more rapidly when the transmitter fires thus preventing damage to the receiver.

keeper—A magnetic conductor placed over the ends of a permanent magnet to protect it against being demagnetized.

kel-f—Polymonochlorotrifluoroethylene—used as a high-temperature insulation (−55°C to +135°C).

Kelvin balance—An instrument for measuring current. This is done by sending it through a fixed and a movable coil attached to one arm of a balance. The resultant force between the coils is then compared with the force of gravity acting on a known weight at the other end of the balance arm.



Kelvin bridge.

Kelvin bridge — Also called a double or Thomson bridge. A seven-arm bridge for comparing the resistances of two 4-terminal resistors or networks. Their adjacent potential terminals are spanned by a pair of auxiliary resistance arms of known ratio, and they are connected in series by a conductor joining their adjacent current terminals.

Kelvin scale—Also called absolute scale. A temperature scale using the same divisions as the Celsius scale, but with the zero point established at absolute zero (≅ −273°C), theoretically the lowest possible temperature.

Kendall effect—A spurious pattern or other distortion in a facsimile record. It is caused by unwanted modulation produced by transmission of a carrier signal. Such modulation appears as a rectified baseband that interferes with the lower sideband of the carrier.

Kennelly-Heaviside layer — *See* Heaviside Layer.

kenopliotron—A diode-triode vacuum tube within one envelope. The anode of the diode also serves as the cathode of the triode.

kenotron—Also called a valve tube. A term used primarily in industrial and X-ray fields for a hot-cathode vacuum tube.

keraunophone—A radio circuit device for audibly demonstrating the occurrence of distant lightning flashes.

kernel—A line within a current-carrying conductor along which the magnetic intensity due to the current is zero.

Kerr cell—A transparent enclosure used as a light valve in some mechanical television systems. It contains a transparent substance which exhibits electric double refraction. Hence, it can convert a varying voltage into corresponding variations in the intensity of a polarized light passing through the cell.

Kerr effect—1. An electro-optical effect in which certain transparent substances become double refracting when subjected to an electric field perpendicular to a beam of light. 2. The conversion of plane into elliptically polarized light when reflected from the polished end of a magnet.

kev—Abbreviation for kilo-electron-volt.

key—1. A hand-operated switching device for switching one or more parts of a circuit. It ordinarily consists of concealed spring contacts and an exposed handle or push button. 2. A projection which slides into a mating slot or groove so as to guide two parts being assembled and assure proper polarization.

keyboard computer—A computer whose input employs a keyboard, e.g., an electric typewriter.

keyboard perforator — A mechanism that punches a paper tape from which messages are automatically transmitted by a transmitter distributor. The keyboard is similar to that of a typewriter and can be operated by any trained typist after a few hours' instruction. As each key is depressed, the tape is punched with corresponding code symbols.

keyboard send/receive—A combination teletypewriter transmitter and receiver with transmission capability from a keyboard only.

key click—Undesired clicking noises caused by the opening and closing of the signaling key.

key-click filter—Also called a click filter. A filter that attenuates the surges produced each time the keying circuit of a transmitter is opened or closed.

keyed agc — Abbreviation for keyed automatic gain control.

keyed automatic gain control—Abbreviated keyed agc. A television automatic gain control in which the agc tube is kept cut off except when the peaks of the positive horizontal-sync pulse act on its grid. The agc voltage is therefore not affected by noise pulses occurring between the sync pulses.

keyed rainbow generator—A color television test instrument which displayes the individual colors of the spectrum, separated by black bars, on the picture tube.

keyed rainbow signal—A 3.563795-MHz (3.56-MHz) continuous sine-wave signal from a color-bar generator that is pulsed on and off. This signal creates a series of different color bars on the screen of the color picture tube. A typical pulse rate (for 10 color bars) is 12 times per 1 horizontal line.

keyer—In telegraphy a device which breaks up the output of a transmitter or other device into the dots and dashes that are used in the code.

keyer adapter—A device that detects a modulated signal and produces a d-c output signal whose amplitude varies in accordance with the modulation. In radio facsimile transmission, it is used to provide the keying signal for a frequency-shift exciter unit.

keying—The forming of signals, such as those employed in telegraph transmission, by an abrupt modulation of the output of a direct- or an alternating-current source (e.g., by interrupting it or by suddenly changing its amplitude, frequency, or some other characteristic).

keying chirps—Sounds accompanying code signals when the transmitter is unstable and shifts slightly in frequency each time the sending key is closed.

keying frequency—In facsimile, the maximum number of times a second a black-line signal occurs while scanning the subject copy.

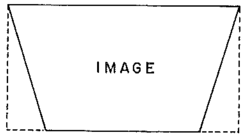
keying wave—Also called marking wave. The emission that takes place in telegraphic communication while the information portion of the code characters is being transmitted.

key pulse—A telephone signaling system in which numbered keys are depressed instead of a dial being turned.

key pulsing—A switchboard arrangement using a nonlocking keyset for the transmission of pulse signals corresponding to the key depressions.

key punch—A keyboard machine for manually punching information into paper tape or cards.

key station—The master station from where a network radio or television program originates.



Keystone distortion.

keystone distortion—1. In a tv receiver, distortion seen as a trapezoidal instead of rectangular raster. 2. The distortion produced when a plane target area not normal to the average direction of the beam is scanned rectilinearly with constant-amplitude sawtooth waves. 3. Camera-tube distortion in which the slope or length of a horizontal line trace or scan line is linearly related to its vertical displacement.

keystone shaped—Wider at the top than at the bottom, or vice versa.

keystoning—The keystone-shaped scanning pattern produced when the electron beam in the television camera tube is at an angle with the principal axis of the tube. (*Also see* Keystone Shaped.)

keyswitch—In an organ, the switch which is closed to allow a tone from the tone generator to sound when a key is depressed.

keyway—The mating slot or groove in which a key slides.

kHz—Abbreviation for kilohertz.

kickback—The voltage developed across an inductance by the sudden collapse of the magnetic field when the current through the inductance is cut off.

kickback power supply—*See* Flyback Power Supply.

kick-sorter—British term for pulse-height analyzer.

Kikuchi lines—A series of spectral lines obtained by the scattering of electrons, when an electron beam is directed against a crystalline solid. The pattern may be interpreted to yield information on the structure of the crystal and its mechanical perfection.

killer circuit—1. The vacuum tube or tubes and associated circuits in which are generated the blanking pulses used to temporarily disable a radar set. 2. In a transponder, a logic circuit that kills replies to side-lobe interrogations.

killer pulse—*See* Suppression Pulse.

kilo—Abbreviated k. A prefix representing 10^3, or 1,000.

kiloampere—1,000 amperes. Abbreviated ka.

kilobit—1,000 bits.

kilocycle (kc)—1,000 cycles. Generally interpreted as meaning 1,000 cycles per second. Obsolete term, replaced by kilohertz (kHz).

kilo-electron-volt—1,000 electron-volts. The energy acquired by an electron that has been accelerated through a voltage difference of 1,000 volts. Abbreviated kev.

kilogauss—1,000 gausses.

kilogram (unit of mass)—The mass of a particular cylinder of platinum-iridium alloy, called the international prototype kilogram, which is preserved in a vault at Sevres, France, by the International Bureau of Weights and Measures.

kilohertz—1,000 hertz. Abbreviated kHz.

kilohm—One thousand ohms. Abbreviated k or kohm.

kilohmmeter—A meter designed for measuring resistance in kilohms.

kilomega (kM)—Obsolete prefix for giga (G), representing 10^9, or 1,000,000,000.

kilomegacycle—Now called gigahertz. One billion cycles per second.

kilometer—One thousand meters, or approximately 3,280 feet.

kilometric waves—British term for electromagnetic waves between 1,000 and 10,000 meters in length.

kilosecond—1,000 seconds.

kilovar—One reactive kilovolt-ampere, or 1,000 reactive volt-amperes. Abbreviated kvar.

kilovar-hour—1,000 reactive volt-ampere-hours.

kilovolt—1,000 volts. Abbreviated kv.

kilovolt-ampere—1,000 volt-amperes. Abbreviated kva.

kilovoltmeter—A voltmeter which reads thousands of volts.

kilowatt—1,000 watts. Abbreviated kw.

kilowatt-hour—The equivalent energy supplied by a power of 1,000 watts for one hour. Abbreviated kwhr.

kine—Slang term for kinescope recording.

kine-klydonograph—An instrument that records the current-time characteristics of a lightning stroke. The instrument records a series of Lichtenberg figures in a manner similar to the field gradient recorder.

kinescope—1. In television receivers, the cathode-ray tube in which the electrical signals are translated into a visible picture on a luminescent screen. 2. A film recording made from a television program on a picture tube and used as a permanent record or for subsequent rebroadcasting.

kinescope recorder—A camera which photographs television images directly from the picture tube onto motion-picture film.

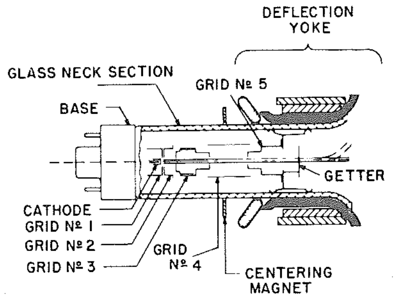
kinetic energy—Energy which a system possesses by virtue of its motion.

Kirchhoff's laws—1. The current flowing to a given point in a circuit is equal to the current flowing away from that point. 2. The algebraic sum of the voltage drops in any closed path in a circuit is equal to the algebraic sum of the electromotive forces in that path. (Laws 1 and 2 are also called Laws of electric networks.) 3. At a given temperature, the emissive power of a body is the same as its radiation-absorbing power for all surfaces.

kit—A prepared package of parts with instructions for assembly and/or wiring a component or chassis (also a small accessory item).

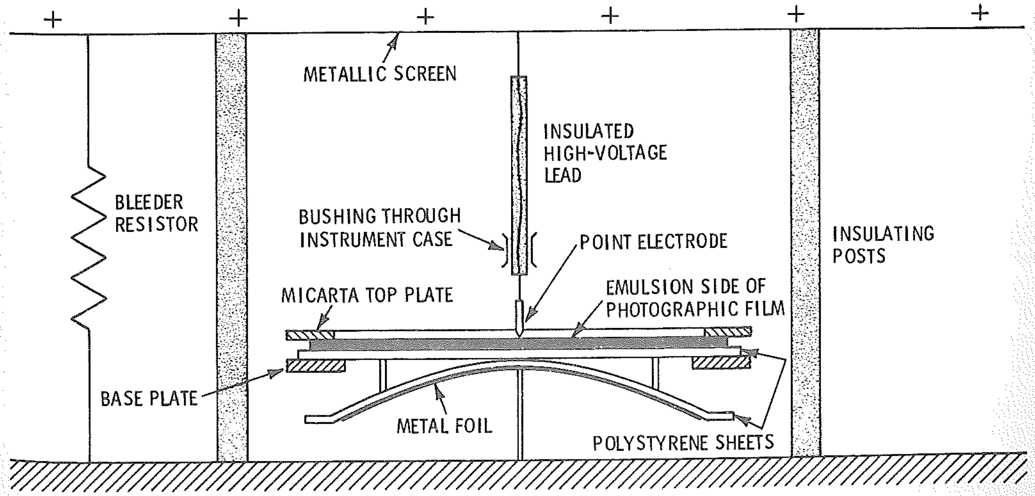
klydonograph—A field gradient recording instrument that registers voltages on photographic film in the form of Lichtenberg figures.

klystron—1. An electron tube used as an oscillator or amplifier in ultrahigh frequencies. The electron beam is velocity-modulated (periodically bunched) to accomplish the desired results. 2. A type of oscillator or amplifier used for the generation or reception of microwave frequencies.



Kinescope.

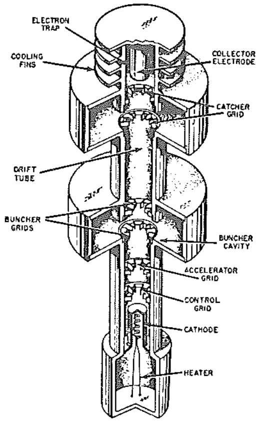
klystron control grid—An electrode which controls the emission, or beam current, of a klystron or other velocity-modulated tube.



Klydonograph gradient recorder.

klystron frequency multiplier—A two-cavity klystron that has the output cavity tuned to a multiple of the fundamental frequency.

klystron generator—A klystron tube used as a generator. Its cavity feeds energy directly into a waveguide.



Cutaway view of klystron tube.

klystron oscillator—An oscillator employing a klystron tube to generate radio-frequency power.

klystron repeater—A klystron tube operated as an amplifier and inserted directly into a waveguide in such a way that incoming waves velocity-modulate the electron stream emitted from a heated cathode. A second cavity converts the energy of the electron clusters into waves of a much higher amplitude and feeds them into the outgoing guide.

kM—Abbreviation for kilomega (an obsolete term).

kmc—Abbreviation for kilomegacycle. Now replaced by gigahertz.

knee—An abrupt change in direction between two relatively straight segments of a curve, such as the region of a magnetization curve near saturation or the top bend of a vacuum-tube characteristic curve.

knife switch—A form of air switch in which a moving element is sandwiched between two contact clips. The moving element is usually a hinged blade, although when it is not, it is removable.

knob—A round, polygonal, or pointer-shaped part which is fastened to one end of a control shaft so that the shaft can be turned more easily. The knob sometimes indicates the degree of rotation also.

knocker—A term used with some fire-control radars to indicate a subassembly comprising synchronizing and triggering circuits. It drives the r-f pulse-generating equipment in the transmitter, and also synchronizes the cycle of operation with the transmitted pulse in range units and indicators.

knockout—A removable portion in the side of a box or cabinet. During installation it can be readily taken out with a hammer, screwdriver, or pliers so the raceway, cables, or fittings can be attached.

knot—One nautical mile (6,080.20 feet, or 1.15 statute miles) per hour.

kohm—Abbreviation for kilohm.

kraft paper—Relatively heavy, high-strength sulfate paper used for electrical insulating material. (Capacitor tissue is kraft paper of normal thickness equal to 0.002 inch or less.)

K-scan—*See* K-Display.

K-series — A series of frequencies in the X-ray spectrum of an element.

KSR—Keyboard send-receive set—A combination transmitter and receiver with transmission capability from the keyboard only (teletypewriter term).

kurtosis — The degree of curvature of the peak of a probability curve.

kv—Abbreviation for kilovolt.

kva—Abbreviation for kilovolt-ampere.

kvar—Abbreviation for kilovar.

kw—Abbreviation for kilowatt.

kwhr—Abbreviation for kilowatt-hour.

kymograph — An instrument for recording wavelike oscillations of varying quantities for medical studies.

L

L—Symbol for coil or inductance.

label—A code name used to identify or classify a name, term, phrase, or document.

labile oscillator—A local oscillator the frequency of which is remote-controlled by a signal received from a radio or over a wire.

laboratory power supply — A regulated d-c source having (a) less than 10-kV output at up to 500 W. (b) Output adjustable over a wide range, usually down to zero. (c) Regulation on the order of ±0.01% static line and load.

labyrinth—Speaker enclosure with absorbing air chambers at the rear to eliminate acoustic standing waves.

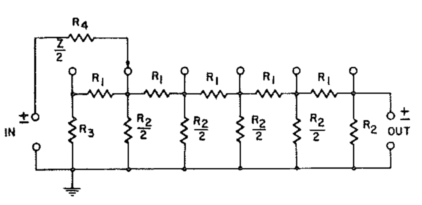
lacquer disc — Also called cellulose-nitrate discs. A mechanical recording disc, usually made of metal, glass, or paper and coated with a lacquer compound often containing cellulose nitrate.

lacquer master—*See* Lacquer Original.

lacquer original—Also called lacquer master. An original recording made on a lacquer surface to be used as a master.

lacquer recording—Any recording made on a lacquer medium.

ladder attenuator—A series of symmetrical sections used in signal generators and other devices where voltages and currents must be reduced in known ratios. They are designed so that the required ratio of voltage loss per section is obtained with image-impedance operation. The impedance between any junction point and common ground in a ladder attenuator is half the image impedance.



Ladder attenuator.

ladder network—Also called series-shunt network. A network composed of H-, L-, T-, or pi-networks connected in series.

LAFOT—Coded weather broadcasts issued by the U. S. Weather Bureau for the Great Lakes region. They are broadcast every six hours by Marine radiotelephone broadcasting stations on their assigned frequencies.

lag—1. The displacement in time, expressed in electrical degrees, between two waves of the same frequency. 2. The time between transmission and reception of a signal. 3. In a television camera tube, the persistence of the electrical-charge image for a time interval equal to a few frames.

lagged-demand meter—A meter in which there is a characteristic time lag, by either mechanical or thermal means, before maximum demand is indicated.

lagging current—The current flowing in a circuit that is mostly inductive. If the circuit contains only inductance, the current lags the applied voltage by 90°. Because of the characteristics of an inductance, the current does not change direction until after the corresponding voltage does.

lagging load — A predominantly inductive load—i.e., one in which the current lags the voltage.

lag-lead (lead-lag)—A circuit the response of which includes lag components and their derivatives.

lambda—Greek letter λ, used to designate wavelength measured in meters.

lambert—A unit of luminance equal to $1/\pi$ candle per square centimeter. It is equal to the uniform luminance of a perfectly diffusing surface emitting or reflecting light at the rate of one lumen per square centimeter.

Lambert's law of illumination—The illumination of a surface on which the light falls normally from a point source is inversely proportional to the square of the distance of the surface from the source. If the normal to the surface makes an angle with the direction of the rays, the illumination is proportional to the cosine of that angle.

laminated—Made of layers.

laminated contact—A switch contact made up of a number of laminations, each making contact with an opposite conducting surface.

laminated core—An iron core for a coil, transformer, armature, etc. It is built up from laminations to minimize the effect of eddy currents. The sheet iron or steel laminations are insulated from each other by surface oxides or by oxides and varnish.

laminated record—A mechanical recording medium composed of several layers of material (normally a thin face of material on each side of a core).

lamination—A single stamping of sheet material used in building up a laminated object such as the core of a power transformer.

Lamont's law—The permeability of steel at any flux density is proportional to the difference between the saturation value of the flux density and its value at the point in question. This law is only approximately accurate and is not true for the initial part of the magnetization curve.

lamp—A device for producing light.

lamp bank—An arrangement of incandescent lamps commonly used as a resistance load during electrical tests.

lamp cord—A twin conductor, either twisted or parallel, used for connecting floor lamps and other electric appliances to wall outlets.

lamp holder—A lamp socket.

Lampkin oscillator—A variation of the Hartley oscillator. Its distinguishing feature is that an approximate impedance match is effected between the tank and grid-cathode circuits.

lamp receptacle—A device that supports an electric lamp and connects it to a power line.

land — 1. The surface between two adjacent grooves of a recording disc. 2. Also called boss, pad, terminal point, blivet, tab, spot, donut. In a printed-circuit board, the conductive area to which components or separate circuits are attached. It usually surrounds a hole through the conductive material and the base material.

Landau damping—The damping of a space-charge wave by electrons moving at the phase velocity of the wave.

landing beacon—The radio transmitter that produces a landing beam for aircraft. (*Also see* Landing Beam.)

landing beam—A highly directive radio signal projected upward from an airport to guide aircraft in making a landing during poor visibility.

landline—A telegraph or telephone line passing over land, as opposed to submarine cables.

landline facilities — Domestic communications common-carrier's facilities that are within the continental United States.

landmark beacon—Any beacon other than an airport or airway beacon.

land mobile service — A radio service in which communication is between base stations and land mobile stations or between land mobile stations.

land mobile station—A two-way mobile station that operates solely on land.

land return—Radiation reflected from nearby land masses and returned to a radar set as an echo.

lands—Bonding points used in the manufacture of microelectronic circuits.

land station—A permanent, or fixed station.

Langevin ion—An electrified particle produced in a gas by an accumulation of ions on dust particles or other nuclei.

Langmuir dark space—The nonluminous region surrounding a negatively charged probe inserted into the positive column of a glow or arc discharge.

language—A set of computer symbols, with rules for their combination. They form a code to express information with fewer symbols and rules than there are distinct expressible meanings.

language converter—A data-processing device designed to change one form of data, i.e., microfilm, strip chart, etc., into another (punch card, paper tape, etc.).

language translation—The transformation of information from one language to another.

L-antenna—An antenna consisting of an elevated horizontal wire to which a vertical lead is connected at one end.

lanyard—A device which is attached to certain quick-disconnect connectors and which permits uncoupling and separation of connector halves by a pull on a wire or cable.

lap dissolve—In motion pictures or television, simultaneous transition in which one scene is faded down and out while the next scene is faded up and in.

lapel microphone—A microphone worn on the user's clothing.

Laplace's law—The strength of the magnetic field at any given point due to any element of a current-carrying conductor is directly proportional to the strength of the current and the projected length of the element, and is inversely proportional to the square of the distance of the element from the point in question.

Laplace transform—A mathematical substitution the use of which permits the solution of a certain type of differential equation by algebraic means.

lapping—Bringing quartz crystal plates up to their final frequency by moving them over a flat plate over which a liquid abrasive has been poured.

lap winding—An armature winding in which opposite ends of each coil are connected to adjoining segments of the commutator so that the windings overlap.

lap wrap—Tape wrapped around an object in an overlapping condition.

large-scale integrated circuit—An integrated circuit which contains 100 gates or more on a single chip, resulting in an increase in the scope of the function performed by a single device.

large-signal characteristics—The characteristics of an amplifier when rated (full) output signals are produced.

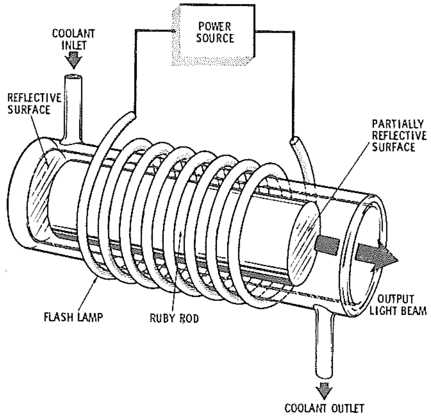
large-signal, d-c current gain—The d-c output current of a transistor with the d-c output circuit shorted, divided by the d-c input current producing the d-c output current.

large-signal power gain—The ratio of the a-c output power to the a-c input power under specified large-signal conditions. Usually expressed in decibels (db).

large-signal, short-circuit, forward-current transfer ratio—In a transistor, the ratio under specified test conditions of a change in output current to the corresponding change in input current.

Larmor orbit—The path of circular motion of a charged particle in a uniform magnetic field. The motion of the particle is unimpeded in the direction of the magnetic field, but motion perpendicular to the direction of the field is always accompanied by a force perpendicular to the direction of motion and the field.

laryngaphone—Also called a throat microphone. A microphone applied to the throat of a speaker to pick up voice vibrations directly. It is very useful in noisy locations because it picks up only the speaker's voice—no outside noises.



Laser.

laser—A device for transforming incoherent light of various frequencies of vibration into a very narrow, intense beam of coherent light. The name is derived from the initial letters of "Light Amplification by Stimulated Emission of Radiation." In the emission of ordinary light the molecules or atoms of the source emit their radiation independently of each other, and consequently there is no definite phase relationship among the vibrations in the resultant beam. The light is incoherent. The laser, by means of an optical resonator, forces the atoms of the material of the resonator to radiate in phase. The emitted radiation is stimulated by the excitation of atoms to a higher energy level by means of energy supplied to the device.

In the microwave region, the corresponding device is called a maser, and hence the laser is also known as a light maser.

laser cavity—An optical resonant and hence mode-selecting low-loss structure in which laser action occurs through the build-up of electromagnetic field intensity upon multiple reflection.

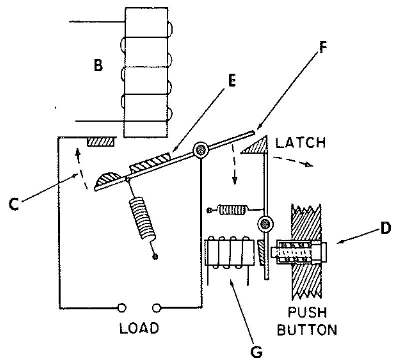
laser diode—*See* Diode Laser.

laser ranger—A device similar to conventional radar but using high intensity light rather than microwaves.

laser welding—A method of welding in which material heating is accomplished by concentration of a beam of coherent light on the area until fusion of the materials takes place.

lasing—In a laser, the generation of visible or infrared light waves that have very nearly a single frequency, by pumping or exciting electrons into high-energy states.

latching relay—A relay with contacts that lock in either the energized or de-energized positions, or both, until reset either manually or electrically.



Latch-in relay.

latch-in relay—Also called locking relay. A relay with contacts which remain energized or de-energized until reset manually or electrically.

latch mode—A mode of operation for a storage circuit in which all encoder contact closures, even momentary ones, are latched "on."

latch-up—1. A condition in which the collector voltage in a given circuit does not return to the supply voltage when a transistor is switched from saturation to cutoff. Instead, the collector finds a stable operating point in the avalanche region of the collector characteristics. 2. An unintended stable circuit mode which will not revert to a previous intended circuit mode after removal of a stimulus such as a spurious signal or radiation. The effect is usually caused by parasitic circuit elements.

late contacts—In a relay, contacts that open or close after other contacts when the relay operates.

latency—1. The time required by a digital computer to deliver information from its memory. 2. In a serial-storage system, the access time minus the word time.

latent image—A stored image (e.g., the one contained in the charged mosaic capacitance in an iconoscope).

lateral chromatic aberration—Aberration which affects the sharpness of images off the axis. This occurs because different colors produce different magnifications.

lateral compliance—The force required to move the reproducing stylus from side to side as it follows the modulation on a laterally recorded record.

lateral-correction magnet—In a three-gun picture tube, an auxiliary component used for positioning the blue beam horizontally so that beam convergence will be obtained. It operates on the principle of magnetic convergence and is used in conjunction with a set of pole pieces mounted on the focus element of the blue gun.

lateral forced-air cooling—A method of heat transfer which employs a blower to produce side to side circulation of air through or across the heat dissipators.

lateral recording—A mechanical recording in which the groove modulation is perpendicular to the direction of motion of the recording medium and parallel to its surface.

lattice—1. In navigation, a pattern of identifiable intersection lines placed in fixed positions with respect to the transmitters that establish it. 2. The geometrical arrangement of atoms in a crystalline material.

lattice network—A network composed of four branches connected in series to form a mesh. Two nonadjacent junction points serve as input terminals, and the remaining two as output terminals.

lattice structure—In a crystal, a stable arrangement of atoms and their electron-pair bonds.

lattice-wound coil—*See* Honeycomb Coil.

launch complex—The entire launch, control, and support system required for launching rockets.

launching—The transferring of energy from a coaxial cable or shielded paired cable into a waveguide.

lavalier microphone—A small microphone suspended from the neck by a cord or wire. Used mainly in broadcasting and public-address applications, it frees the speaker's hands.

LAWEB—Weather bulletins issued every 6 hours. They are given in layman's language from ship and shore positions along the Great Lakes during the navigation season. Part 1 is from land stations, and Part 2 is from a ship four or more miles off shore with the ship's position given.

lawn mower—In facsimile, a term often used when referring to a helix-type recorder mechanism.

law of electric charges—Like charges repel; unlike charges attract. (*Also see* Coulomb's Law.)

law of electromagnetic induction—*See* Faraday's Laws.

law of electromagnetic systems—1. Any two circuits carrying currents tend to dispose themselves in such a way that the flux of magnetic induction linking the two will be a maximum. 2. Every electromagnetic system tends to change its configuration so that the flux of magnetic induction will be a maximum.

law of electrostatic attraction—*See* Coulomb's Law.

law of magnetism—Like poles repel; unlike poles attract.

law of normal distribution—The Gaussian law of the frequency distribution of any normal, repetitive function. It describes the probability of the occurrence of deviants from the average.

law of reflection—The angle of reflection is equal to the angle of incidence—i.e., the incident, reflected, and normal rays all lie in the same plane.

laws of electric networks—*See* Kirchhoff's Laws.

lay—Pertaining to wire and cable, the axial distance required for one cable conductor or conductor strand to complete one revolution about the axis around which it is cabled.

layer—The consecutive turns of a coil lying in a single plane.

layer-to-layer adhesion—The tendency for adjacent layers of recording tape in a roll to adhere, particularly after prolonged storage under conditions of high temperature and/or humidity.

layer-to-layer signal transfer—The magnetization of a layer of tape in a roll by the field from a nearby recorded layer. The magnitude of the induced signal tends to increase with storage time and temperature, and to decrease after the tape is unwound. These changes are a function of the magnetic instability of the oxide.

layer winding—A coil-winding method in which adjacent turns are placed side by side and touch each other. Additional layers may be wound over the first and are usually separated by sheets of insulation.

layout—1. Diagram indicating the positions of parts on a chassis or panel. 2. The actual positions of the parts themselves.

L-band—A radio-frequency band of 390 to 1,550 MHz and corresponding wavelengths of 77 to 19 cm.

LC product—Inductance (L) in henrys multiplied by capacitance (C) in farads.

L/C ratio—Inductance in henrys, divided by capacitance in farads.

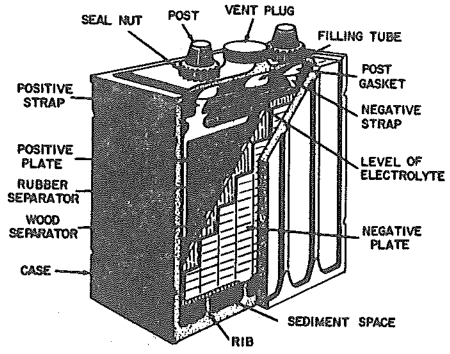
LCS—Abbreviation for loudness-contour selector.

LCVD—*See* Least Voltage Coincidence Detection.

L-display—Also called L-scan. A radar display in which the target appears as two horizontal blips to the right and left of a central vertical time base.

lead—1. A wire to or from a circuit element. 2. To precede (the opposite of lag).

lead-acid cell—Also called lead cell. A cell in an ordinary storage battery. It consists of electrodes (plates) immersed in an electrolyte of dilute sulphuric acid. The electrodes contain certain lead oxides that change their composition as the cell is charged or discharged.



Lead-acid cell.

lead cell—*See* Lead-Acid Cell.

lead-covered cable—A cable with a lead sheath. The sheath offers protection from the weather and mechanical damage to wires contained.

leader cable—A navigational aid in which the path to be followed is defined by a magnetic field around a cable.

leader tape—Also called timing tape. Plain nonmagnetic tape for splicing to either end of magnetic tape to facilitate threading and preserve recorded material, or for splicing between recorded tapes to separate selections or provide pauses.

lead-in—The conductor that provides the path for r-f energy between the antenna and the radio/television receiver or transmitter.

leading blacks—Also called edge effect. In a television picture, the condition where the edge preceding a white object is overshaded toward black (i.e., the object appears to having a preceding, or leading, black border).

leading current—Current that reaches maximum before the voltage that produces it does. A leading current flows in any predominantly capacitive circuit.

leading edge—The major portion of the rise of a pulse.

leading-edge pulse time—The time required by a pulse to rise from its instantaneous amplitude to a stated fraction of its peak amplitude.

leading ghost—A twin image appearing to the left of the original in a televised picture.

leading load—A predominantly capacitive load—i.e., one in which the current leads the voltage.

lead-in groove—Also called a lead-in spiral. A blank spiral groove around the outside of the record. Its pitch is usually much greater than the other grooves and is used to quickly lead the needle into the beginning of the recorded groove.

leading whites—Also called edge effect. In a television picture, the condition where the edge preceding a black object is shaded toward white (i.e., the object appears to have a preceding, or leading, white border).

lead-in insulator—A tubular insulator through which cables or wires are brought inside a building.

lead-in spiral—*See* Lead-in Groove.

lead-in wires—Wires which carry current into a building (e.g., from an antenna).

lead network—A network, either a-c or d-c, designed to provide error-rate damping in the controlling device of a servo system.

lead-out groove—Also called a throw-out spiral. A blank spiral groove on the inside of a recording disc, next to the label. It is generally much deeper than the recording groove and is connected to either the locked or eccentric groove.

lead-over groove—Also called a crossover spiral. On disc records containing several selections, the groove in which the needle travels as it crosses from one selection to the next.

lead polarity of a transformer—Also called polarity. A designation of the relative instantaneous directions of currents in the leads of the transformer. Primary and secondary leads are said to have the same polarity when, at a given instant, the current enters the primary lead in question and leaves the secondary lead in question in the same direction as though the two leads formed a continuous circuit. The lead polarity of a single-phase distribution or power transformer may be either additive or subtractive. If one pair of adjacent leads from the two windings in question is connected together and voltage is applied to one of the windings, a. the lead polarity is additive if the voltage across the other two leads of the windings in question is greater than that of the higher-voltage winding alone. b. the lead polarity is subtractive if the voltage across the other two leads of the winding in question is less than that of the higher-voltage winding alone.

lead screw—1. In recording, a threaded rod which guides the cutter or reproducer across the surface of a disc. 2. In facsimile, a threaded shaft which moves the scanning mechanism or drum lengthwise.

leakage—1. Electrical loss from poor insulation. 2. Undesired flow of electricity over or through an insulator. 3. The portion not utilized most effectively in a magnetic field (e.g., at the end pieces of an electromagnet).

leakage coefficient—Ratio of total to useful flux produced in the neutral section of a magnet.

leakage current—1. An undesirable small value stray current which flows through (or across the surface of) an insulator or the dielectric of a capacitor. 2. A current which flows between two or more electrodes in a tube other than across the interelectrode space.

leakage flux—The flux which does not pass through the air gap, or useful part, of the magnetic circuit.

leakage inductance—A self-inductance due to the leakage flux generated in the winding of a transformer.

leakage power—In TR and pre-TR tubes, the radio-frequency power transmitted through a fired tube.

leakage radiation—Spurious radiation in a transmitting system—i.e., radiation from other than the system itself.

leakage reactance—The reactance represented by the difference in value between two mutually coupled inductances when their fields are aiding and then opposing.

leakage resistance—The normally high resistance of the path over which leakage current flows.

leakance—The reciprocal of insulation resistance.

leaky—Usually applied to a capacitor in which the resistance has dropped so far below normal that leakage current flows.

leaky waveguide—A waveguide with a narrow longitudinal slot, permitting a continuous energy leak.

leaky waveguide antenna—An antenna constructed from a long waveguide with radiating elements along its length. It has a very sharp pattern.

leapfrogging—The process of phasing, or delaying, the ranging pulse of a tracking radar in order to move, or shift (on the scope presentation), the tracking gate (at target blip) past the target blip from another radar.

"leapfrog" test—Slang for a program designed to uncover malfunctions in a digital computer.

least maximum deviation—A manner of expressing nonlinearity as a deviation from a straight line for which the deviations for proportional or normal linearity are minimized.

least mechanical equivalent of light—The radiant power that is contained in one lumen at the wavelength of maximum visibility. It is equal to 1.46 milliwatts at a wavelength of 555 millimicrons.

least voltage coincidence detection—A system that provides protection against interfering signals by blocking all signals except those having a pulse-repetition frequency the same as or some exact multiple of the radar-set pulse-repetition frequency. Abbreviated LCVD.

Lecher line—*See* Lecher Wire.

Lecher oscillator—A device for producing standing waves on two parallel wires called Lecher wires.

Lecher wire—Also called Lecher line. Two parallel wires on which standing waves are set up, usually for the measurement of wavelength.

Leclanche cell—An ordinary dry cell. It is a primary cell with a positive electrode of carbon and a negative electrode of zinc in an electrolyte of sal ammoniac and a depolarizer of manganese dioxide.

left-handed polarized wave—Also called counterclockwise-polarized wave. An elliptically polarized transverse-electromagnetic wave in which the electric intensity vector rotates counterclockwise (looking in the direction of propagation).

left-hand rule—*See* Fleming's Rule.

left-hand taper—The greater resistance in the counterclockwise half of the operating range of a rheostat or potentiometer than in the clockwise half (looking from the shaft end).

left (or right) signal—The electrical output of a microphone or combination of microphones placed so as to convey the intensity, time, and location of sound originating predominantly to the listener's left (or right) of the center of the performing area.

left (or right) stereophonic channel—The left (or right) signal as electrically reproduced in the reception of f-m stereophonic broadcasts.

leg—A section or branch of a component or system (e.g., one of the windings of a transformer).

legend—A table of symbols or other data placed on a map, chart, or diagram to assist the reader in interpreting it.

Lenard rays—Cathode rays that emerge from a special vacuum tube through a thin glass window or metallic foil.

Lenard tube—An electron tube in which the beam can be taken through a section of the wall of the evacuated enclosure.

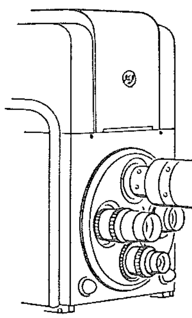
length of a scanning line—1. The length of the path traced by the scanning or recording spot as it moves from line to line. 2. On drum-type equipment, the circumference of the drum. 3. The spot speed divided by the scanning-line frequency.

lens—1. An optical device which focuses light by refraction. 2. An electrical device which focuses microwaves by refraction or diffraction. 3. An acoustic device which concentrates sound waves by refraction. 4. An electronic optical device which focuses electrons.

lens disc—A television scanning disc having a number of openings arranged in a spiral, with a lens set into each opening.

lens speed—The amount of light a lens will pass. It is equal to the focal length divided by the diameter of the lens.

lens turret—On a camera, an arrangement which accommodates several lenses and can be rotated to facilitate their rapid interchange.



Lens turret.

Lenz's law—The current induced in a circuit due to a change in the magnetic flux through it or to its motion in a magnetic field is so directed as to oppose the change in flux or to exert a mechanical force opposing the motion. If a constant current flows in a primary circuit A and if by motion of A or the secondary circuit, B, a current is induced in B, the direction of the induced current will be such that, by its electromagnetic action on A, it tends to oppose the relative motion of the circuits.

Lepel discharger—A quenched spark gap used in early radio-telegraph transmitters employing shock excitation.

let-through current—The current that actually passes through a circuit breaker under short-circuit conditions.

level—The magnitude of a quantity in relation to an arbitrary reference value. Level normally is stated in the same units as the quantity being measured (e.g., volts, ohms, etc.). However, it may be expressed as the ratio to a reference value (e.g., db—as in blanking level, transmission level, etc.).

level above threshold—Also called sensation level. The pressure level of a sound in decibels above its threshold of audibility for the individual listener.

level compensator—1. An automatic gain control which minimizes the effect of amplitude variations in the received signal. 2. A device that automatically controls the gain in telegraph-receiving equipment.

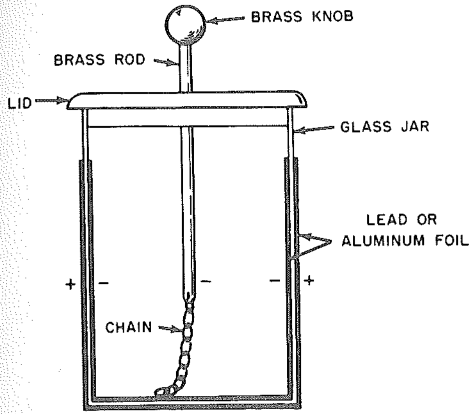
level indicator—A sound-volume indicator.

lever switch—Commonly referred to as a key lever or lever key. A hand-operated switch for rapidly opening and closing a circuit.

Leyden jar—The original capacitor. It consists of metal foil sheets on the inside and outside of a glass jar. The foil serves as the plates and the glass as the dielectric.

lf—Abbreviation for low frequency—(i.e., between 30 and 300 kHz).

LFM—A vhf fan-type marker. It is low powered (5 watts) and has a range of only 10 miles or less.



Leyden jar.

library—In computer programming, a collection of standard and fully tested routines and subroutines by which problems and parts of problems may be solved.

Lichtenberg figure camera—Also called klydonograph or surge-voltage recorder. A device for indicating the polarity and approximate crest value of a voltage surge by the appearance and dimensions of the Lichtenberg figure produced on a photographic plate or film. The emulsion coating of the plate or film contacts a small electrode coupled to the circuit in which the surge occurs. The film is backed by an extended plane electrode.

lie detector—Also called a polygraph. An electronic instrument which measures the blood pressure, temperature, heart action, breathing, and skin moisture of the human body. Abrupt or violent changes in these variables indicate the subject is not telling the truth.

life—The expected number of full excursions over which a transducer would operate within the limits of the applicable specification.

life test—The test of a component or unit under the conditions which approximate, or stimulate by acceleration, a normal lifetime of use. The test is performed to determine life expectancy or reliability throughout a predetermined life expectancy.

lifetime—The average time interval between the introduction and recombination of minority carriers in a semiconductor.

lifting magnet—A powerful electromagnet used on the end of a crane to lift iron and steel objects. They can be dropped instantly by merely cutting off the current.

light—1. Radiant energy within the wavelength limits perceptible by the average human eye (roughly, between 400 and 700 millimicrons). Although ultraviolet and infrared emissions will excite some types of photocells, they are usually not considered light. 2. In combination with other terms, a device used as a source of luminous energy (e.g., a pilot light).

light-activated silicon controlled rectifier—A silicon controlled rectifier with the ability to be triggered by current to the gate terminal, or by a light flashed on a light-sensitive part of the semiconductor pellet.

light-activated switch—A semiconductor diode which is triggered into conduction by light irradiation of a light-sensitive part of the semiconductor pellet.

light amplifier—A solid-state amplifier using photoconductive and electroluminescent films.

light-beam instrument—An instrument in which a beam of light is the indicator.

light-beam pickup—A phonograph pickup utilizing a beam of light as a coupling element of the transducer.

light chopper—A device for interrupting a light beam. It is frequently used to facilitate amplification of the output of a phototube on which the beam strikes.

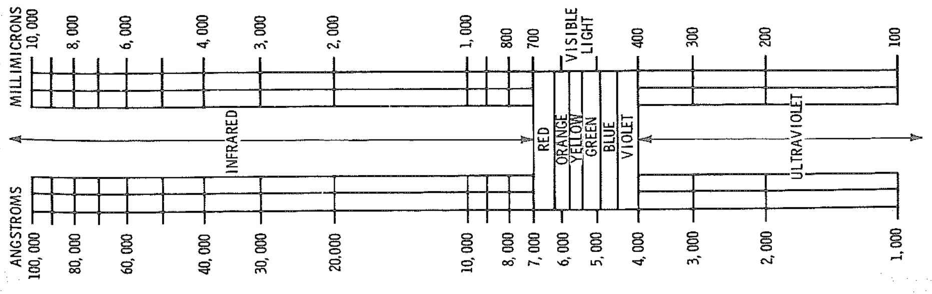
light-dimming control—A circuit, often employing a saturable reactor, used to control the brightness of the lights in theaters, auditoriums, etc.

light-emitting diode—A PN junction that emits light when biased in the forward direction.

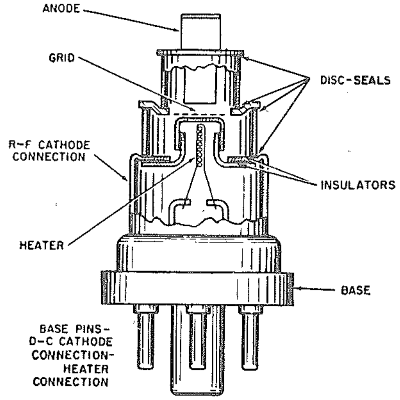
light flux—*See* Luminous Flux.

light gun—A photoelectric cell used by computer operators to take specific actions in assisting and directing computer operation. So called because of its gunlike case.

lighthouse tube—1. An ultrahigh-frequency



Light (spectrum).



Cutaway view of lighthouse tube.

electron tube shaped like a lighthouse and having disc-sealed planar elements. 2. *See* Disc-Seal Tube.

lighting outlet—An outlet for direct connection of a lamp holder, lighting fixture, or pendant cord terminating in a lamp holder.

light load—A fraction of the total load the device is designed to handle.

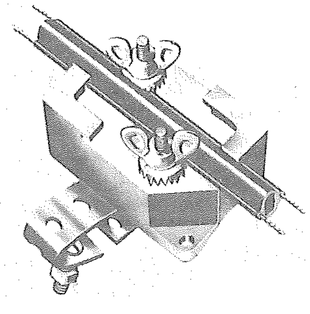
light microsecond—The unit for expressing electrical distance. It is the distance over which light travels in free space in one microsecond (i.e., about 983 feet, or 300 meters).

light modulation—Variation in the intensity of light, usually at audio frequencies, for communications or motion-picture sound purposes.

light modulator—The device for producing the sound track on a motion-picture film. It consists of a source of light, an appropriate optical system, and a means for varying the resulting light beam (such as a galvanometer or light valve).

light negative—Having a negative photoconductivity—i.e., decreasing in conductivity when subjected to light.

lightning arrester—A device containing spark gaps, which allow lightning currents to flow into the earth.



Lightning arrester.

lightning generator—A generator of high-voltage surges (e.g., for testing insulators).

lightning rod—A rod projecting above the highest point on a structure and connected to ground in such a way that it can carry a lightning discharge to ground.

lightning surge—A transient disturbance in an electric circuit caused by lightning.

lightning switch—A switch for connecting a radio antenna to ground during electrical storms.

light pen—A small photocell or photomultiplier in a pen-shaped housing, which is held against a cathode-ray screen so as to detect the very instant the electron beam goes through that particular location during its scanning sweep.

light pipe—An optical transmission element in which unfocused transmission and reflection are used to reduce photon losses.

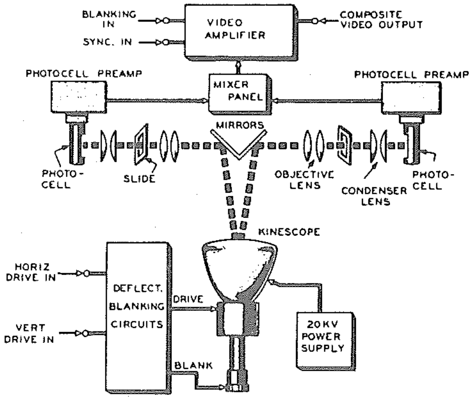
light-positive—Having positive photoconductivity—i.e., increasing in conductivity when subjected to light.

light ray—A very thin beam of light.

light relay—A photoelectric device that opens or closes a relay when the intensity of a light beam changes.

light sensitive—Exhibiting a photoelectric effect when irradiated (e.g., photoelectric emission, photoconductivity, and photovoltaic action).

light-sensitive tube—A vacuum tube that changes its electrical characteristics with the amount of illumination.



Light-spot scanner.

light-spot scanner—Also called a flying-spot scanner. A television camera in which the source of illumination is a spot of light that scans the scene to be televised. The picture signal is generated in a phototube, which picks up light either transmitted through the scene or reflected from it.

light valve—A device the light transmission of which can be varied in accordance with an externally applied electrical quantity such as voltage, current, an electric or magnetic field, or an electron beam.

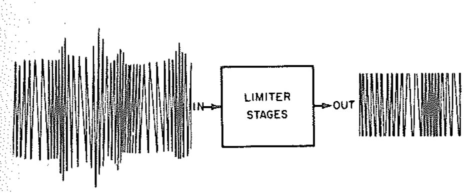
light-year—The distance traveled by light in one year, or about 5,880,000,000,000 miles.

limit bridge—A form of Wheatstone bridge used for rapid routine production testing. Conformity with tolerance limits, rather than exact value, is determined.

limited signal—In radar, a signal that is intentionally limited in amplitude by the dynamic range of the system.

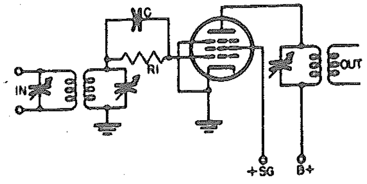
limited space-charge accumulation—A mode of oscillation for gallium arsenide diodes.

limited stability—The property of a system which remains stable only as long as the input signal falls within a particular range.



Limiter action.

limiter—1. A device in which some characteristic of the output is automatically prevented from exceeding a predetermined value—e.g., a transducer in which the output amplitude is substantially linear (with regard to the input) up to a predetermined value and substantially constant thereafter. 2. A radio-receiver stage or circuit that limits the amplitude of the signals and hence keeps interfering noise low by removing excessive amplitude variations from the signals.



Limiter circuit.

limiting—The restricting of the amplitude of a signal so that interfering noise can be kept to a minimum.

limiting resolution—In television, a measure of the resolution usually expressed in terms of the maximum number of lines per picture height discriminated on a test chart.

limits—The minimum and maximum values specified for a quantity.

limit switch—A mechanically operated contact-making or -breaking device mounted in the path of a moving object and actuated by its passage.

line—1. In television, a single trace of the electron beam from left to right across the screen. The present United States standard is based on 525 lines to a complete picture. 2. A conductor of electrical energy. 3. The path of the moving spot in a cathode-ray tube 4. A term used interchangeably for maxwell.

line advance—Also called line feed. The distance between the centers of the scanning lines.

line amplifier—An amplifier that supplies a program transmission line or system with a signal at a specified level.

linear—Having an output that varies in direct proportion to the input.

linear acceleration—The rate of change in linear velocity.

linear accelerator—A device for speeding up charged particles such as protons. It differs from other accelerators in that the particles move in a straight line instead of in circles or spirals.

linear accelerometer—A transducer for measuring linear accelerations.

linear actuator—An actuator which produces mechanical motion from electrical energy.

linear amplification—Vacuum-tube amplification in which the plate current changes in direct proportion to the applied grid voltage.

linear amplifier—An amplifier that develops an output directly proportionate in amplitude to that of the input signal.

linear array—An antenna array in which the elements are equally spaced and in a straight line.

linear circuit—A circuit the output of which is an amplifier version of its input or a predetermined variation of its input.

linear control—A rheostat or potentiometer having uniform distribution of graduated resistance along the entire length of its resistance element.

linear detection—Detection in which the output voltage is substantially proportionate to the input voltage over the useful range of the detector.

linear detector—A detector that produces an output signal directly proportionate in amplitude to the variations in amplitude (for a-m transmission) or frequency (for f-m transmission) of the r-f input.

linear differential transformer—A type of electromechanical transducer that converts physical motion into an output voltage, the phase and amplitude of which are proportional to position. *Also see* Linear Motion Transducer.

linear distortion—Amplitude distortion in which the output- and input-signal envelopes are not proportionate, but no alien frequencies are involved.

linear electrical parameters of a uniform line—Frequently called the linear electrical constants. The series resistance and inductance, and the shunt conductance and capacitance, per length of a line.

linear electron accelerator—An evacuated metal tube in which electrons are accelerated through a series of small gaps (usually cavity resonators in the high-frequency range). The gaps are so spaced that, at a specific excitation frequency, the electrons gain additional energy from the electric field as they pass through successive gaps.

linear feedback-control system—A feedback-control system in which the relationship between the pertinent measures of the system signals are linear.

linearity—1. The relationship existing between two quantities when a change in a second quantity is directly proportionate to a change in the first quantity. 2. Deviation from a straight-line response to an input signal. 3. The ability of a meter to provide equal angular deflections proportional to the applied current. Usually expressed as a percent of the full-scale deflection.

linearity control—A manual control for adjusting the scanning waveshapes in television receivers.

linearity error—The deviation of a calibration curve from a specified straight line.

linear logarithmic intermediate-frequency amplifier—An amplifier used to avoid overload or saturation as a protection against jamming in a radar receiver.

linearly polarized wave—At a point in a homogeneous isotropic medium, a transverse electromagnetic wave the electric field vector of which lies along a fixed line.

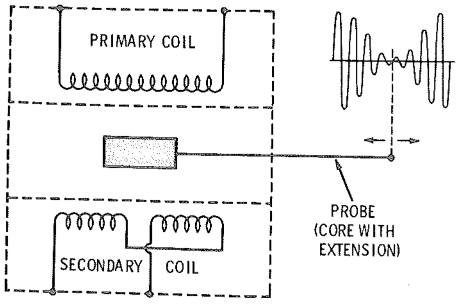
linear magnetostriction—Under stated conditions, the relative change of length of a ferromagnetic object in the direction of magnetization when the magnetization of the object is increased from zero to a specified value (usually saturation).

linear mobility—The synchronized incremental mobility of functionally transitional electrons in a semiconductor.

linear modulation—Modulation in which the amplitude of the modulation envelope (or the deviation from the resting frequency) is directly proportionate to the amplitude of the modulating wave at all audio frequencies.

linear modulator—A modulator in which the modulated characteristic of the output wave is substantially linear with respect to the modulating wave for a given carrier magnitude.

linear motion transducer—An instrumentation component that translates straight-line (linear) mechanical motion into an a-c analog which is usable as a feedback signal for control or display. A transformer-type device in which a movable magnetic core is displaced axially by the moving component being monitored. When the core is moved in one direction from the center of its stroke, the output voltage is in phase with the excitation voltage, and when the core is moved in the opposite direction from the center, the output voltage is 180° out of phase. At the center, the output voltage is (virtually) zero. In either direction from the center, the voltage increases as a precise linear function of probe displacement. Thus the output signal has two basic analog components; phase relationship wth the excitation voltage, indicating the direction of travel; and voltage amplitude, indicating the length of travel.



Linear motion transducer.

linear polarization—The polarization of a wave radiated by an electric vector that does not rotate but that alternates so as to describe a line. Normally the vector is oriented either horizontally or vertically.

linear power amplifier—A power amplifier in which the output voltage is directly proportionate to the input voltage.

linear programming—In computers, a mathematical method of sharing a group of limited resources among a number of competing demands. All decisions are interlocking because they must be made under a common set of fixed limitations.

linear pulse amplifier—A pulse amplifier which maintains the peak amplitudes of the input and output pulses in proportion.

linear rectification—The production, in the rectified current or voltage, of variations that are proportionate to variations in the input-wave amplitude.

linear rectifier—A rectifier with the same output-current or -voltage waveshape as that of the impressed signal.

linear scan—A radar beam which traverses only one arc or circle.

linear scanning—Scanning in which a radar beam generates only one arc or circle.

linear sweep—In a television receiver, the spot sweeps across the screen at a uniform velocity. This is due to a periodic voltage which, when applied to the horizontal-deflection plates of the cathode-ray tube, increases linearly to maximum and then falls abruptly to zero.

linearsyn—A linear displacement pick-off of the differential-transformer type consisting of a coil assembly and a moveable magnetic core. Linear velocity units of high-coercive-force permanent magnetic cores which induce sizable d-c voltages while moving concentrically within shielded coils; the voltage varies linearly with the core velocity. (Sanborn Co.)

linear taper—A potentiometer which changes the resistance linearly as it is rotated through its range.

linear time base—In a cathode-ray tube, the

time base in which the spot moves at a constant speed along the time scale. This type of time base is produced by application of a sawtooth waveform to the horizontal-deflection plates of a cathode-ray tube.

linear transducer—A transducer for which the pertinent measures of all the waves concerned are related by a linear function (e.g., a linear algebraic differential, or integral equation).

linear variable-differential transformer—*See* Differential Transformer.

linear varying parameter network—A linear network in which one or more parameters vary with time.

linear velocity transducer—A transducer which produces an output signal proportionate to the velocity of single-axis translational motion between two objects.

line balance—1. The degree to which the conductors of a transmission line are alike in their electrical characteristics with respect to each other, other conductors, and ground. 2. Impedance equal to that of the line at all frequencies (e.g., in terminating a two-wire line).

line-balance converter—A device used at the end of a coaxial line to isolate the outer conductor from ground.

line circuit—In a telephone system, the relay equipment associated with each station connected to a dial or manual switchboard. The term is also applied to a circuit for interconnecting an individual telephone and a channel terminal.

line coordinate—In a matrix, a symbol (normally at the side) identifying a specific row of cells and, in conjunction with a column coordinate, a specific cell.

line cord—Also called a power cord. A two-wire cord terminating in a two-prong plug at the end that goes to the supply, and connected permanently into a radio receiver or other appliance at the other end.

line-cord resistor—An asbestos-enclosed, wire-wound resistance element incorporated into a line cord along with the two regular wires. It lowers the line voltage to the correct value for the series-connected tube filaments and pilot lamps of a universal a-c/d-c receiver.

line diffuser—A circuit used to produce small vertical oscillations of the spot on the screen of a television monitor or receiver to make the line structure of the image less noticeable to an observer close to the screen.

line drop—A voltage loss occurring between any two points in a power or transmission line. Such a loss, or drop, is due to the resistance, reactance, or leakage of the line. An example is the voltage drop between a power source and load when the line supplying the power has excessive resistance to the amount of current.

line-drop signal—A signal associated with a subscriber line on a manual switchboard.

line-drop voltmeter compensator—A device using a voltmeter to enable it to indicate the voltage at some distant point in the circuit.

line equalizer—An inductance and/or capacitance inserted into a transmission line to correct its frequency-response characteristics.

line-equipment balancing network—A hybrid network designed to balance filters, composite sets, and other line equipment.

line feed—*See* Line Advance.

line filter—1. A device containing one or more inductors and capacitors. It is inserted between a transmitter, receiver, or appliance and the power line to block noise signals. In a radio receiver, it prevents power-line noise signals from entering the receiver. In other appliances, it prevents their own electrical noises from entering the power line. 2. A filter associated with a transmission line. In some applications, line filter may imply a filter used to separate the speech frequencies. In other applications, it may imply directional separation, etc.

line-filter balance—A network designed to maintain phantom-group balance when one side of the group is equipped with a carrier system. Since the network must balance the phantom group for voice frequencies only, its configuration is much simpler than the filter it balances.

line-focus tube—An X-ray tube in which the focal spot is roughly a line.

line frequency—1. Also called horizontal line frequency or horizontal frequency. In television, the number of times per second the scanning spot crosses a fixed vertical line in the picture in one direction, including vertical-return intervals. 2. The frequency of the supply voltage.

line-frequency regulation—The change in output (current, voltage, or power) of a regulated power supply for a specified change in line frequency.

line group—The frequency spectrum occupied by a group of carrier channels as they are applied to a transmission facility.

line hit—An electrical interference causing the introduction of spurious signals on a circuit.

line hydrophone—A directional hydrophone consisting of a single straightline element, an array of adjacent electroacoustic transducing elements in a straight line, or the acoustic equivalent of such an array.

line impedance—The impedance measured across the terminals of a transmission line.

line interlace—*See* Interlaced Scanning.

line leakage—Resistance existing through the insulation between the two wires of a telephone-line loop.

line lengthener—A device for altering the electrical length of a waveguide or transmission line, but not its physical length or other electrical characteristics.

line level—The intensity of the signal at a certain position on a transmission line.

line load—Usually a percentage of maximum circuit capability to reflect actual use during a period of time (e.g., peak-hour line load).

line loop—An operation performed over a communication line from an input unit at one terminal to output units at a remote terminal.

line loop resistance—Also called loop resistance. The metallic resistance of the local loop.

line loss—The total of the various energy losses in a transmission line.

line microphone—A directional microphone consisting of a single straight-line element, an array of adjacent electro-acoustic transducing elements in a straight line, or the acoustical equivalent of such an array.

line noise—Noise originating in a transmission line.

line of force—In an electric or magnetic field, an imaginary line in the same direction as the field intensity at each point. Sometimes called a maxwell when used as a unit of magnetic flux.

line of propagation—The path over which a radio wave travels through space.

line of sight—1. The distance to the horizon from an elevated point, including the effects of atmospheric refraction. The line-of-sight distance for an antenna at zero height is zero. 2. A straight line between an observer or radar antenna and a target. 3. An unobstructed, or optical, path between two points. 4. The radio-propagation characteristic of a microwave.

line-of-sight coverage—The maximum distance for transmission above the highest usable frequency. Radio waves at those frequencies do not follow the curvature of the earth and are not reflected from the ionosphere, but go off into space and are lost.

line-of-sight stabilization—In shipboard or airborne radar, compensating for the roll and pitch by automatically changing the elevation of the antenna in order to keep the beam pointed at the horizon.

line of travel—The path followed by an electromagnetic wave from one point to another.

line oscillator—An oscillator in which the resonant circuit is a section of transmission line an integral number of quarter wavelengths in electrical length.

line pad—In radio broadcasting, a pad inserted between the final program amplifier and the transmitter to insure a constant load on the amplifier.

line printer—In computers, a high-speed printer which produces an entire line at one time. All characters of the alphabet are contained around the rim of a continuously rotated disc, and there are as many discs as there are characters in the line. The computer momentarily stops the discs at the right characters for each line, and stamps out an impression in a fraction of a second.

line pulsing—A method of pulsing a transmitter by charging an artificial line over a relatively long period, and then discharging it through the transmitter tubes at a shorter interval determined by the line characteristics.

line regulation—The change in output (current, voltage, or power) of a regulated power supply for a specified change in line voltage. It may be stated as a percentage of the specified output and/or an absolute value.

line relay—A relay activated by the signals on a line.

line-sequential color-television system—A color-television system in which the individual lines of green, red, and blue are scanned in sequence rather than simultaneously.

line spectrum—The spectrum of a periodic, discrete signal consisting of one or more frequencies. For example, a square wave is characterized by a fundamental and odd-order harmonics.

line-stabilized oscillator—An oscillator in which the frequency is controlled by using one section of a line as a sharply selective circuit.

line stretcher—A section of rigid coaxial line with telescoping inner and outer conductors that permit the section to be conveniently lengthened or shortened.

line switching—Also called circuit switching. A communications switching system which completes a circuit from sender to receiver at the time of transmission, as opposed to message switching.

line transformer—A transformer inserted into a system for such purposes as isolation, impedance matching, or additional circuit derivation.

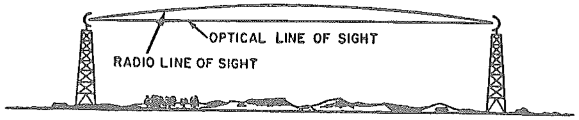
line triggering—Triggering from the power-line frequency.

line unit—An electric device used in sending, receiving, and controlling the impulses of a teletypewriter.

line voltage—The voltage level of the main power supply to the equipment.

line-voltage regulator—A device that counteracts variations in the power-line voltage and delivers a constant voltage to the connected load.

linguistic—Pertaining to language or its study, including its origin, structure, phonetics, etc.



Line of sight.

link—1. A transmitter-receiver system connecting two locations. 2. In a digital computer, the part of a subprogram that connects it with the main program. 3. An interconnection. 4. In automatic switching, a path between two units of switching apparatus within a central office.

linkage—1. A measure of the voltage that will be induced in a circuit by magnetic flux. It is equal to the flux times the number of turns linked by the flux. 2. A mechanical arrangment for transferring motion in a desired manner. It consists of solid pieces with movable joints. 3. In a computer, a technique used to provide interconnections for entry and exit of a closed subroutine to or from the main routine.

link circuit—A closed loop used for coupling purposes. It generally consists of two coils, each having a few turns of wire, connected by a twisted pair of wires or by other means, with each coil placed over, near, or in one of the two coils to be coupled.

link coupling—Inductive coupling between circuits. A coil in one circuit acts as the primary, and a coil in the second circuit as the secondary.

link fuse—An unprotected fuse consisting of a short, bare wire between two fastenings.

link neutralization—Neutralization of a tuned radio-frequency amplifier by means of an inductive coupling loop from the output to the input.

link transmitter—In broadcasting, a booster for a remote pickup or from studio to main transmitter.

lin-log receiver—A radar receiver in which the amplitude response is linear for small-amplitude signals and logarithmic for large ones.

lip microphone—A sensitive microphone which is placed in contact with the lip.

liquid-borne noise—Undesired sound characterized by fluctuations of pressure of a liquid about the static pressure as a mean.

liquid cooling—The use of a circulating liquid to cool components or equipment that heat up during operation.

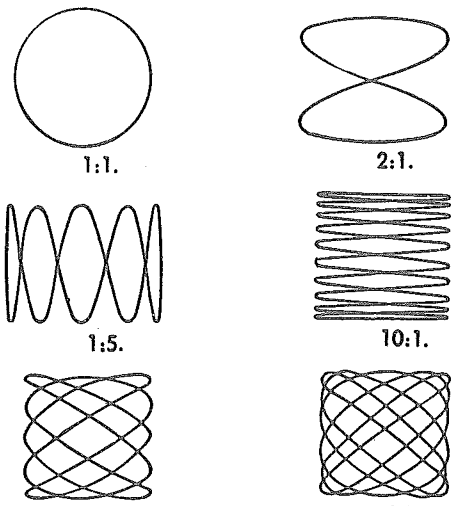
liquid-filled capacitor—A capacitor in which a liquid impregnant occupies substantially all of the case volume not required by the capacitor element and its connections. Space may be allowed for the expansion of the liquid under temperature variations.

liquid fuse unit—A fuse unit in which the fuse link is immersed in a liquid or the arc is drawn into the liquid when the fuse link melts.

liquid-impregnated capacitor—A capacitor in which a liquid impregnant is dominantly contained within the foil and paper winding, but does not occupy substantially all of the case volume not required by the capacitor element and its connections.

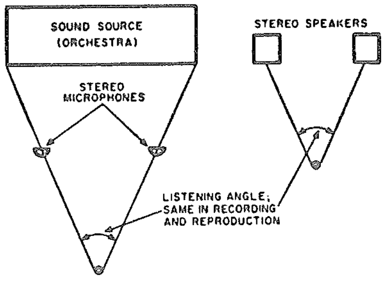
liquid rheostat—A rheostat consisting of metal plates immersed in a conductive liquid. The resistance is changed by raising or lowering the plates or the liquid level to vary the area of the plates contacting the liquid.

liser—A microwave oscillator of very high spectrum purity. Its emission consists of right circularly polarized waves of two different cavity resonant frequencies.



Lissajous figure.

Lissajous figures—Patterns produced on the screen of a cathode-ray tube when sine-wave signal voltages of various amplitude and phase relationships are applied to the horizontal- and vertical-deflection circuits simultaneously.



Listening angle.

listening angle—The enclosed angle between the listener and the two speakers of a stereo reproducing system.

listening sonar—*See* Sonar.

lithium—An alkali metal used in the construction of photocells.

litz wire—Also called Litzendraht wire. A conductor composed of a number of fine, separately insulated strands which are woven together so that each strand successively takes up all possible positions in the cross section of the entire conductor. Litz wire gives reduced skin effect; hence, lower resistance to high-frequency currents.

live—A term applied to a circuit through which current is flowing. *Also see* Energized.

live cable test cap—A protective cap placed over the end of a cable to insulate the cable and seal its sheath.

live end—The end of a radio studio where the reflection of sound is greatest.

live room—A room with a minimum of sound-absorptive material such as drapes, upholstered furniture, rugs, etc. Because of the many reflecting surfaces, any sound produced in the room will have a long reverberation time.

L-network—A network composed of two impedance branches in series. The free ends are connected to one pair of terminals, and the junction point and one free end are connected to another pair.

load—1. The power consumed by a machine or circuit in performing its function. 2. A resistor or other impedance which can replace some circuit element. 3. The power delivered by a machine. 4. A device that absorbs power and converts it into the desired form. 5. The impedance to which energy is being supplied. 6. Also called work. The material heated by a dielectric or induction heater. 7. In a computer, to fill the internal storage with information obtained from auxiliary or external storage.

load and go — In a computer, an operation and compiling technique in which the pseudo language is converted directly to machine language and the program is then run without the creation of an output machine-language program.

load balance—*See* Load Division.

load circuit—The complete circuit required to transfer power from a source to a load (e.g., an electron tube).

load-circuit efficiency—In a load circuit, the ratio between its input power and the power it delivers to the load.

load-circuit power input—The power delivered to the load circuit. It is the product of the alternating components of the voltage across the load circuit and the current passing through it (both root-mean-square values), times their power factors.

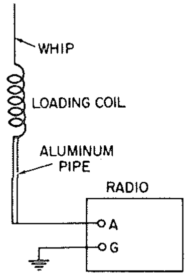
load coil—Also called a work coil. In induction heaters a coil which, when energized with an alternating current, induces energy into the item being heated.

load curve—A curve of power versus time—i.e., the value of a specified load for each unit of the period covered.

load divider—A device for distributing power.

load division — Also called load balance. A control function that divides the load in a prescribed manner between two or more power sources supplying the same load.

loaded antenna—An antenna to which extra inductance or capacitance has been added to change its electrical (but not its physical) length.



Center-loaded antenna.

loaded applicator impedance—In dielectric heating, the complex impedance measured at the point of application with the load material properly positioned for heating and at the specified frequency.

loaded impedance—In a transducer, the impedance at the input when the output is connected to its normal load.

loaded line — A transmission line that has lumped elements (inductance or capacitance) added at uniformly spaced intervals. Loading is used to provide a given set of characteristics to a transmission line.

loaded motional impedance—*See* Motional Impedance.

loaded *Q*—Also called the working *Q*. The *Q* of an electric impedance when coupled or connected under working conditions.

load factor—The ratio of average power demand, over a stipulated period of time, to the peak or maximum demand for that same interval.

load impedance—The impedance which the load presents to a transducer.

loading—1. In communication practice, the insertion of reactance into a circuit to improve its transmission characteristics. 2. Placing some material at the front or rear of a speaker so as to change its acoustic impedance and thus alter its radiation pattern.

loading coil—An inductor inserted into a circuit to increase its inductance and thereby improve its transmission characteristics.

loading-coil spacing—The line distance between the successive loading coils of a line.

loading disc—A metal disc placed on top of a vertical antenna to increase its natural wavelength.

loading error—The error introduced when more than negligible current is drawn from the output of a device.

loading noise—Any unwanted signal caused by fluctuating contact resistance between the slider and the wire or film in a potentiometric transducer when current is drawn from the instrument.

loading routine — In a computer, a routine which, when in the memory, is able to read other information into the memory from cards, tape, etc.

load isolator — A waveguide or coaxial device (usually ferrite) which provides a good energy path from a signal source to a load, but provides a poor energy path for reflections from a mismatched load back to the signal source.

load life—The ability of a device to withstand its full power rating over an extended period of time, usually expressed in hours.

load line—1. A straight line drawn across a series of plate-current-plate-voltage characteristic curves on a graph to show how plate current changes with grid voltage when a specified plate-load resistance is used. 2. A line drawn on the collector characteristic curves of a transistor on which the operating point of the transistor moves as the collector current changes. Called a load line because the slope of the line depends on the value of the collector load resistance.

load matching—In induction and dielectric heaters, adjustment of the load-circuit impedance so that the desired energy will be transferred from the power source to the load.

load-matching network—An electrical impedance network inserted between the source and the load to provide for maximum transfer of energy.

load-matching switch—In induction and dielectric heaters, a switch used in the load-matching network to alter its characteristics and thereby compensate for a sudden change in the load characteristics (such as in passing through the Curie point).

load point — The physical beginning of a magnetic tape recording as determined by a reflective spot attached to the tape at that point.

load regulation — In a power supply, the change in output for a specified change in load conditions. It may be stated as a percentage of the specified output or as an absolute value.

loadstone—*See* Lodestone.

load-transfer switch—A switch for connecting either a generator or a power source to one load circuit or another.

lobe — Also called directional, radiation, or antenna lobe. One of the areas of greater transmission in the pattern of a directional antenna. Its size and shape are determined by plotting the signal strength in various directions. The area with the greatest signal strength is known as the major lobe, and all others are called minor lobes.

lobe frequency—The number of times a lobing pattern is repeated per second.

lobe half-power width—In a plane containing the direction of the maximum energy of the lobe, the angle between the two directions in that plane about the maximum in which the radiation intensity is one-half the maximum value of the lobe.

lobe penetration — The penetration of the radar coverage of a station which is not limited by the pulse-repetition frequency, scope limitations, or the screening angle at the azimuth of penetration.

lobe switching—A form of scanning in which the maximum radiation or reception is periodically switched to each of two or more directions in turn.

lobing—The formation of maxima and minima at various angles of the vertical-plane antenna pattern by the reflection of energy from the surface surrounding the radar antenna. These reflections reinforce the main beam at some angles and detract from it at other angles, producing finders of energy.

local action—In a battery, the loss of otherwise usable chemical energy by currents which flow within regardless of its connections to an external circuit.

local battery—A battery made of single dry cells located at the subscriber's station.

local channel—1. In private line services, that portion of a through channel wthin an exchange which is provided to connect the main station with an interexchange channel. 2. A standard broadcast channel in which several stations, with powers not in excess of 250 watts, may operate.

local control—Control of a radio transmitter control directly at the transmitter, as opposed to remote control.

localizer—A radio which provides signals for guiding aircraft onto the center line of a runway.

localizer on-course line—A vertical line passing through a localizer. Indications of opposite sense are received on either side of the line.

local oscillator—Also called beating oscillator. An oscillator used in a superheterodyne circuit to produce a sum or difference frequency equal to the intermediate frequency of the receiver. This is done by mixing its output with the received signal.

local-oscillator injection — An adjustment used to vary the magnitude of the local-oscillator signal that is coupled into the mixer.

local-oscillator radiation—Radiation of the fundamental or harmonics of the local oscillator of a superheterodyne receiver.

local-oscillator tube — The vacuum tube which provides the local-oscillator signal in a superheterodyne receiver.

local program—A program originating at and released through only one broadcast station.

locating lug—The selection of two elements at specified attenuation points or in specified attenuation ranges so the ratio of the outputs of the elements at these points, calculated as a power ratio, do not exceed a specified limit.

location—A unit-storage position in the main or secondary storage of a computer.

location counter—In the control section of a computer, a register which contains the address of the instruction currently being executed.

locked groove—Also called concentric groove. The blank and continuous groove in the center, near the label, of a disc record. It prevents the needle from traveling farther inward, onto the label.

locked-rotor current—In a motor, the steady-state current taken from the line while the rotor is locked and the rated voltage (and frequency in alternating-current motors) is applied to the motor.

locked-rotor torque—Also called static torque. The minimum torque a motor will develop at rest, for all angular positions of the rotor, when the rated voltage is applied at rated frequency.

lock-in—1. The term used when a sweep oscillator is in synchronism with the applied sync pulses. 2. The shifting and automatic holding of one or both of the frequencies of two oscillating systems which are coupled together, so that the two frequencies have the ratio of two integral numbers.

locking—1. Controlling the frequency of an oscillator by means of an applied signal of constant frequency. 2. Automatic following of a target by a radar antenna.

locking circuit—*See* Holding Circuit.

locking-in—In two oscillators which are coupled together, the shifting and automatic holding of one or both of their frequencies so that the two frequencies are in synchronism (i.e., have the ratio of two integral numbers).

locking-out relay—An electrically operated hand or electrically reset device which functions to shut down and hold an equipment out of service on the occurrence of abnormal conditions.

locking relay—*See* Latch-in Relay.

lock-on—1. The instant at which radar begins to track a target automatically. 2. Signifies that a tracking or target-seeking system is continuously and automatically tracking a target in one or more coordinates.

lock-on range—The range from a radar to its target at the instant when lock-on occurs.

lockout—*See* Receiver Lockout System.

lock-up relay—A relay that is locked in the energized position magnetically or electrically rather than mechanically.

loctal base—*See* Loktal Base.

lodar—Also called lorad. A direction finder which compensates for night effect by observing the distinguishable ground- and sky-wave loran signals on a cathode-ray oscilloscope and positioning a loop antenna to obtain a null indication of the more suitable components.

lodestone—Also spelled loadstone. A natural magnet consisting chiefly of a magnetic oxide of iron called magnetite.

Loftin-White circuit—A type of direct-coupled amplifier circuit.

log—1. A listing of radio stations and their frequency, power, location, and other pertinent data. 2. A record of the station with which a radio station has been in communication. Amateur radio operators, as well as all commercial operators, are required by law to keep a log. 3. At a broadcast station, a detailed record of all programs broadcast by the station. 4. At a broadcast transmitter, a record of the meter readings and other measurements required by law to be taken at regular intervals. 5. Abbreviation for logarithm.

logarithmic amplifier—An amplifier the output of which is a logarithmic (as opposed to linear) function of its input.

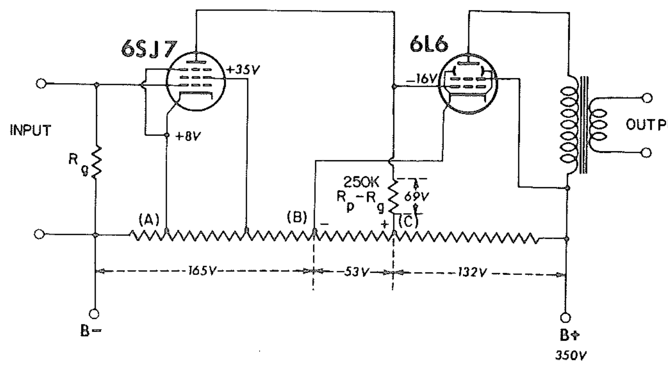
logarithmic curve—A curve on which one coordinate of any point varies in accordance with the logarithm of the other coordinate of the point.

logarithmic decrement—1. For an exponentially damped alternating current, the natural logarithm of the ratio of the first to the second of two successive amplitudes having the same polarity. 2. *See* Damping Ratio.

logarithmic horn—A horn the diameter of which varies logarithmically with the length.

logarithmic scale—A scale on which the various points are plotted according to the logarithm of the number with which the point is labeled.

logarithmic scale meter—A meter having deflections proportional to the logarithms of the applied energies.



Loftin-White amplifier.

logger—An instrument which automatically scans conditions (temperature, pressure, humidity) and records (logs) the findings on a chart.

logic—1. The science dealing with the basic principles and applications of truth tables, switching, gating, etc. 2. *See* Logical Design. 3. Also called symbolic logic. A mathematical approach to the solution of complex situations by the use of symbols to define basic concepts. The three basic logic symbols are "and", "or", and "not." When used in Boolean algebra, these symbols are somewhat analogous to addition and multiplication.

logical choice—In a computer, the correct decision where alternatives or different possibilities are open.

logical design—1. The preplanning of a computer or data-processing system prior to its detailed engineering design. 2. The synthesizing of a network of logical elements to perform a specified function. 3. The result of 1 and 2 above, frequently called the logic of the system, machine, or network.

logical element—In a computer or data-processing system, the smallest building blocks which operators can represent in an appropriate system of symbolic logic. Typical logical elements are the AND gate and the "flip-flop."

logical operations—The operations in which logical quantities (yes-no decisions, quantities expressed as zeros and ones, etc.) make comparisons, decisions, and extractions.

logical threshold voltage—At the output of a logic device, the voltage level at which the following logic device switches states.

logic array—An integrated device in which 50 or more circuits are integral to a single silicon chip. In addition, the circuits are interconnected on the chip to form some electronic function at a higher level of organization than a single circuit. Logic arrays are constructed by the unit cell method in which a simple circuit (or function) is repeated many times on a slice. The interconnection pattern for converting groups of cells into large functions is determined after cell probe tests are completed. Each interconnection pattern may be unique to a single slice. In general, logic arrays are characterized by multiple levels of metallization to effect the large-scale function.

logic diagram—In logical design, a diagram representing the logical elements and their interconnections, but not necessarily their construction or engineering details.

logic symbol—A symbol used to represent a logical element on a graph.

log/linear preamplifier—A preamplifier the electrical output of which is proportional to the common logarithm of the input, but which can be switched to a different mode wherein the output is proportional to the input. Any amplifier the transfer characteristic or calibration curve of which can be arbitrarily switched from the form y — log x to the form y — x (y equals the output and x equals the input).

log-periodic antenna—A type of directional antenna that achieves its wideband properties by geometric iteration. The radiating element and the spacing between elements have dimensions that increase logarithmically from one end of the array to the other so that the ratio of element length to element spacing remains constant.

log receiver—A receiver in which the output amplitude is proportionate to the logarithm of the input amplitude.

log scan—A spectrum display in which the frequency axis is calibrated logarithmically.

loktal base—Also spelled loctal. An eight-pin base for small vacuum tubes. It is designed so that it locks the tube firmly in a corresponding eight-hole socket. Unlike in other tubes, the pins are sealed directly into the glass envelope.

loktal tube—Also spelled loctal. A vacuum tube with a loktal base.

long base-line system—A system in which the distance separating ground stations approximates the distance to the target being tracked.

long-distance navigational aid—A navigational aid usable beyond radio line of sight.

longevity—The period of time during which the failure rate of a group of components is essentially constant.

longitudinal chromatic aberration—A lack of sharpness in the image because different colors come to a focus at different distances from the lens.

longitudinal coils—The coils that are used in transmission lines to suppress longitudinal currents.

longitudinal current—A current which flows in the same direction in both wires of a parallel pair. The earth is its return path.

longitudinal magnetization—In magnetic recording, magnetization of the recording medium in a direction essentially parallel to the line of travel.

longitudinal redundance—In a computer, a condition in which the bits in each track or row of a record do not total an even (or odd) number. The term is generally used to refer to records on magnetic tape, and a system can have either odd or even longitudinal parity.

longitudinal wave—A wave in which the direction of displacement and propagation are the same at each point.

long-persistence screen—A fluorescent screen in which the light intensity of its spots does not immediately die out after the beam has moved on.

long-play record—Abbreviated LP record. Also called a microgroove record. A 10- or 12-inch record or transcription with finely-cut grooves which give it a long playing time.

long-pull magnet—An electromagnet designed to exert a practically uniform pull, for an extended range of armature movement. It consists of a conical plunger moving up and down inside a hollow core.

long-range radar—A radar installation capable of detecting targets 200 or more miles away.

long-range navigation — A long-range electronic navigation system which uses the time divergence of pulse-type transmission from two or more fixed stations.

long shunt—A shunt field connected across the series field and the armature, instead of directly across the armature alone, of a motor or generator.

long-tailed pair—A two-tube circuit in which decreased plate current through one tube results in increased plate current through the other tube, and vice versa.

long-term stability (or long-term instability)—The slow changes in average frequency arising from changes in an oscillator. Statements of long-term stability for quartz oscillators often term this characteristic "aging rate" and specify it as "parts per day" (fractional frequency change over 24 hours). For cesium standards, this term commonly refers to the total fractional frequency drift for the life of the cesium beam tube.

long throw—A method of speaker design in which the woofer moves freely through long excursions, providing excellent low-frequency response with low distortion.

long wave—Wavelengths longer than about 1,000 meters. They correspond to frequencies below 300 kHz.

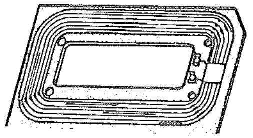
long-wire antenna—A linear antenna which is much longer than the operating wavelength. For this reason, it can provide a directional pattern.

lookthrough—1. In jamming, sporadic interruption of the emission for extremely short periods in order to monitor the victim signal. 2. When a set is being jammed, the monitoring of the desired signal during lulls in the jamming signals.

loom—A flexible nonmetallic tubing placed around insulated wire for protection.

loop—*See* Mesh *and* Antinodes.

loop actuating signal—The signal derived from mixing the loop-input and loop-feedback signals.



Loop antenna.

loop antenna—An antenna used in radio direction-finding apparatus and modern radio receivers. It consists of one or more loops of wire.

loopback test—A test in which signals are looped from a test center through a data set or loopback switch and back to the test for measurement. *Also see* Bussback.

loop control — The maintaining of a specified loop of material between two sections of a machine by automatically adjusting the speed of at least one of the driven sections.

loop difference signal—The output signal from a summing point of a feedback control loop. It is a specific type of loop actuating signal produced by a particular loop input signal applied to that summing point.

loop error—The desired value minus the actual value of the loop output signal.

loop error signal—The loop actuating signal, when it is the loop error.

loop feedback signal—The signal derived from the loop output signal and fed back to the mixing point for control purposes.

loop feeder—A feeder which follows along a circuit and distributes the voltage more evenly at different points.

loop gain—1. The total usable power gain of a carrier terminal or two-wire repeater. Because any closed system tends to sing (oscillate), its usable gain may be less than the sum of the enclosed amplifier gains. The maximum usable gain is determined by—and cannot exceed—the losses in the closed path. 2. The increase in gain observed when the feedback path of an amplifier is opened, but with all circuit loads intact. 3. In an operational amplifier circuit, the product of the transfer characteristics of all of the elements (active or passive) encountered in a complete trip around the loop, starting at any point and returning to that point.

looping — A computer operation in which a sequence of steps is repeated.

loop input signal—An external signal applied to a feedback control loop.

loop-mile—The length of wire in a mile of two-wire line.

loop output signal—The controlled signal extracted from a feedback control loop.

loop pulsing—Also called dial pulsing. The regular, momentary interruption of the direct-current path at the sending end of a transmission line.

loop resistance—*See* Line Loop Resistance.

loop return signal—The signal returned, via a feedback control loop, to a summing point in response to a loop input signal applied to that summing point. The loop return signal is a specified type of loop input signal and is subtracted from it.

loopstick antenna—*See* Ferrite-Rod Antenna.

loop test—A method of locating a fault in the insulation of a conductor when the conductor can be arranged to form part of a closed circuit.

loop transfer function—The transfer function of the transmission path. It is formed by opening and properly terminating a feedback loop. (*Also see* Transfer Function.)

loose coupler—An obsolete tuning system consisting of two coils, one inside the other. Coupling was varied over a wide range by sliding one coil over the other.

loose coupling — Also called weak coupling. A degree of coupling that is considerably less than critical coupling. Hence, there is very little transfer of energy.

Lorac—A trademark of Seismograph Service Corp. for a specific navigation system that determines a position fix by the intersection of lines of position. Each line is defined by the phase angle between two heterodyne beat-frequency waves. One wave is the beat frequency between two c-w signals from two widely spaced transmitters. The other is a reference wave of the same frequency and is obtained by deriving the heterodyne beat of the same two c-w signals at a fixed location and transmitting it, via a second radio-frequency channel, to the receiver being located.

lorad—*See* Lodar.

loran—A contraction of LOng-RAnge Navigation. A navigation aid sending out pulses at radio frequencies between 1,800 and 2,000 kHz. It defines lines of position which are based on the differences in travel time between radio waves from a master and a slave station. Airborne equipment utilizes a picture tube and measuring circuits to determine the time differences and relate them to time-difference lines drawn on a map. A navigation fix is established by the intersection of two or more lines of position.

loran-C — A hyperbolic navigation system that relies on the stability of electromagnetic propagational characteristics at a frequency of 100 kHz. Each loran-C station operates in a pulse mode in such a way that no two stations can be received simultaneously. During the transmission period of the master station, both slave stations remain silent. After a fixed delay time, slave X will transmit a similar pulse. After a second delay, slave Y will transmit a pulse.

loran line—A line of position on a loran chart where each line is the locus of points, the distances from two fixed stations of which differ by a constant amount.

loran station—A radionavigational land station transmitting synchronized pulses.

loran tables—Tables giving terrestrial coordinates (latitude and longitude) of loran lines of position and values of the sky-wave correction.

Lorentz force — The force exerted by an electric field and a magnetic field on a moving electric charge.

Lorentz force equation—An equation relating the force on a charged particle to its motion in an electromagnetic field.

lorhumb line—In navigation, a course line in a lattice; the derivation of one coordinate from the other is always equal to the ratio of the difference between coordinates at the beginning and ending of the course line.

loss—1. A decrease in power suffered by a signal as it is transmitted from one point to another. It is usually expressed in decibels. 2. Energy dissipated without accomplishing useful work.

loss angle—The complement of the phase angle of an insulating material.

losser—A circuit having less power in the output as compared to the power applied to the input. This term is particularly applicable to mixers; a crystal mixer is a losser.

losser circuit—A resonant circuit having sufficient high-frequency resistance to prevent sustained oscillation at the resonant frequency.

losser effect—Radiation resulting from the recombination of charge carriers injected in a PN or PIN junction biased in the forward direction.

Lossev effect—The resultánt radiation when charge carriers recombine after being injected into a forward-biased PN or PIN junction.

loss factor—The characteristic which determines the rate at which heat is generated in an insulating material. It is equal to the dielectric constant times the power factor.

loss index—The product of the power factor times the dielectric constant of a material.

lossless line—A theoretically perfect line—i.e., one that has no loss and hence transmits all the energy fed to it.

loss modulation—*See* Absorption Modulation.

loss tangent — Also called dielectric dissipation factor. The decimal ratio of the irrecoverable to the recoverable part of the electrical energy introduced into an insulating material by the establishment of an electric field in the material.

lossy—Insulating material which dissipates more than the usual energy.

lossy attenuator—A length of waveguide made from some dissipative material and used to deliberately introduce transmission loss.

lossy line—1. A transmission line designed with high attenuation. 2. Cable used in test measurements which has a large attenuation per unit length.

lot — A group of similar components which have been either all manufactured in a continuous production run from homogeneous raw materials under constant process conditions or assembled from more than one production run and submitted for random sampling and acceptance testing. Specifically, a quantity of material all of which was manufactured under identical conditions, and assigned an identifying lot number.

lot tolerance percent defective—A process average that will be rejected 90% of the time. Abbreviated LTPD.

loudness—The intensive attribute of an auditory sensation, in terms of which sounds may be ordered on a scale extending from soft to loud. Loudness depends primarily upon the sound pressure of the stimulus, but it also depends upon the frequency and waveform of the stimulus.

loudness contour — A curve showing the sound pressure required at each frequency to produce a given loudness sensation to a typical listener.

loudness-contour selector — Abbreviated as LCS. A circuit that alters the frequency response of an amplifier so that the characteristics of the amplifier will more closely match the requirements of the human ear.

loudness control—Also called compensated volume control. A combined volume and tone control which boosts the bass frequencies at low volume to compensate for the inability of the ear to respond to them. Some loudness controls provide similar compensation at the treble frequencies.

loudness level—The sound-pressure level of a 1,000-Hz tone judged by a listener to be as loud as the sound under consideration. It is measured in decibels relative to .0002 microbar.

loudspeaker—*See* Speaker.

loudspeaker dividing network—*See* Dividing Network.

loudspeaker impedance—*See* Speaker Impedance.

loudspeaker system—*See* Speaker System.

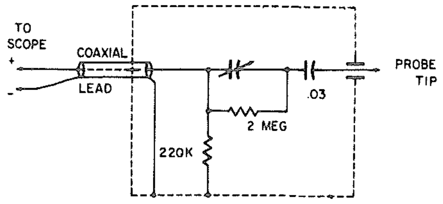
loudspeaker voice coil—*See* Speaker Voice Coil.

louver—The grill of a speaker.

low-angle radiation—Radiation that proceeds at low angles above ground.

low band—Television channels 2 through 6 covering frequencies between 54 and 88 MHz.

low-capacitance contacts—A type of contact construction providing small capacitance between contacts.



Low-capacitance probe circuit.

low-capacitance probe—A probe with very low capacitance. It is connected between the input of an oscilloscope and the circuit under observation.

low-corner frequency — The frequency at which the output of a resolver is 3 db below the mid-frequency value and the phase shift is 45°.

low-definition television—A television system employing less than 200 scanning lines per frame.

low-energy circuit—Also called a dry circuit. A circuit application that functions at low voltage (i.e., approximately 10 volts or less) and low current (i.e., approximately 1 ma or less).

low-energy criterion — *See* Von Hippel Breakdown Theory.

low-energy material — *See* Soft Magnetic Material.

lower manual—*See* Accompaniment Manual.

lower sideband—The lower of two frequencies or groups of frequencies produced by the amplitude-modulation process.

lowest effective power—The minimum product of the antenna input power in kilowatts and the antenna gain required for satisfactory communication over a particular radio route.

lowest useful high frequency—In radio transmission, the lowest frequency effective at a specified time for ionospheric propagation of radio waves between any two points, excluding frequencies below several megahertz. It is determined by such factors as absorption, transmitter power, antenna gain, receiver characteristics, type of service, and noise conditions.

low filter—An audio circuit designed to remove low-frequency noises from the program material. Such noises include turntable rumble, tone-arm resonance, etc.

low frequency—Abbreviated lf. The band of frequencies extending from 30 to 300 kHz (1,000 to 10,000 meters).

low-frequency compensation—A technique for extending the low-frequency response of a broad-band amplifier.

low-frequency impedance corrector — An electric network designed to be connected to a basic network, or to a basic network and a building network, so that the combination will simulate, at low frequencies, the sending-end impedance, including the dissipation, of a line.

low-frequency induction heater or furnace —A heater or furnace in which the charge is heated by inducing a current at the power-line frequency through it.

low-frequency padder—In a radio receiver, a small adjustable capacitor connected in series with the oscillator tuning coil. During alignment it is adjusted to obtain correct calibration of the circuit at the low-frequency end of the tuning range.

low-level contacts — Contacts that control only the flow of relatively small currents in relatively low-voltage circuits—e.g., alternating currents and voltages encountered in voice or tone circuits, direct current on the order of microamperes, and voltages below the softening voltages on record for various contact materials (that is, 0.080 volt for gold, 0.25 volt for platinum, and the like). Also defined as the range of contact electrical loading where there can be no electrical (arc transfer) or thermal effects and where only mechanical forces can change the conditions of the contact interface.

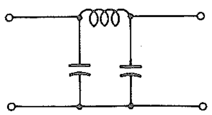
low-level modulation—The modulation produced in a system when the power level at a certain point is lower than it is at the output.

low-level radio-frequency signal (TR, ATR, and pre-TR tubes)—A radio-frequency signal with insufficient power to fire the tube.

low-level signal—Very small amplitudes serving to convey information or other intelligence. Variations in signal amplitude are frequently expressed in microvolts.

low-loss insulator—An insulator with high radio-frequency resistance and hence slight absorption of energy.

low-loss line—A transmission line with relatively low losses.



Low-pass filter.

low-pass filter—A filter network which passes all frequencies below a specified frequency with little or no loss but discriminates strongly against higher frequencies.

low-print tape — Special magnetic recording tape significantly less susceptible to print-through (the transfer of signal from one layer to another), which results when tape is stored for long periods of time. These tapes are especially useful for speech "master recording" (making an original recording from which copies will be made) on professional-quality equipment.

low-rate discharge — The withdrawal of a small current from a cell or battery for long periods of time.

low tension—British term for low voltage. Generally refers to the heater or filament voltage.

low-velocity scanning—The scanning of a target with electrons having a velocity below the minimum required to give a secondary-emission ratio of unity.

low-voltage protection — *See* Undervoltage Protection.

L-pad—A volume control that has practically the same impedance at all settings. It consists essentially of an L-network in which both elements are adjusted simultaneously.

LP record—Abbreviation for long-play record.

L + R, L − R—The sum and difference signals of the two stereo channels; the L + R signals combines the signals of both channels in phase; the L − R signal combines them out of phase. By combining in suitable circuitry, L + R and L − R can be added to obtain 2 L, the signal from one channel; L − R can be subtracted from L + R to obtain 2 R, the signal from the other channel.

LTPD—Abbreviation for lot tolerance percent defective.

L-scan—*See* L-Display.

lug—A device soldered or crimped to the end of a wire lead to provide an eye or fork that can be placed under the head of a binding screw.

lumen—A unit of luminous flux equal to the flux (illumination) on a surface, all points of which are the same distance from a uniform source of one candle.

lumen-hour—A unit of the quantity of light delivered in one hour by a flux of one lumen.

luminaire—A complete lighting unit consisting of a light source, together with a globe, reflector, refractor, housing, socket, and other parts integral with the housing.

luminance—1. The luminous flux emitted, reflected, or transmitted from the source. Usual units are the lumen per steradian per square meter, candle per square foot; meter-lambert, millilambert, and foot-lambert. 2. In color television, the photometric quantity of light radiation.

luminance channel—In a color television system, any path intended to carry the luminance signal. The luminance channel may also carry other signals such as the carrier color, which may or may not be used.

luminance channel bandwidth—The bandwidth of the path intended to carry the luminance signal.

luminance flicker—The flicker resulting from fluctuation of the luminance only.

luminance primary—The one of three transmission primaries whose amount determines the luminance of a color.

luminance signal—Also called Y signal. The signal in which the amplitude varies with the luminance values of a televised scene. It is part of the composite color signal and is made up of 0.30 red, 0.59 green, and 0.11 blue. The luminance signal is capable of producing a complete monochrome picture.

luminescence—1. The absorption of energy by matter, and its subsequent emission as light. If the light is emitted within 10^{-8} second after the energy is absorbed, the process is known as fluorescence. If the emission takes longer, the process is called phosphorescence. 2. The emission of light of certain wavelengths or limited regions of the spectrum in excess of that due to incandescence and the emissivity of the surface. This property is not exhibited by all materials. 3. Light emission without heat.

luminescence threshold—Also called threshold of luminescence. The lowest radiation frequency that will excite a luminescent material.

luminescent—Any material which will give off light but not heat when energized by an external source such as a stream of electrons or radiant energy.

luminescent screen—A screen which becomes luminous in those spots excited by an electron beam. The screen of a cathode-ray tube is the best-known example.

luminosity—Ratio of luminous flux to the corresponding radiant flux at a particular wavelength. It is expressed in lumens per watt.

luminosity coefficients—The constant multipliers for the respective tristimulus values of any color. The sum of the three products is the luminance of the color.

luminosity curve — A distribution curve showing luminous flux per element of wavelength as a function of wavelength.

luminosity factor—For radiation of a particular wavelength, the ratio of the luminous flux at that wavelength to the corresponding radiant flux. It is expressed in lumens per watt. Abbreviated K.

luminous—Emitting light (i.e., glowing).

luminous efficiency—The ratio of luminous flux to radiant flux. It is usually expressed in lumens per watt of radiant flux and should not be confused with the term "efficiency" when applied to a practical source of light. The latter is based on the power supplied to the source—not the radiant flux from the source. For energy radiated at a single wavelength, luminous efficiency is synonymous with luminosity.

luminous flux—Also called light flux. Time rate of flow of light (the total visible energy produced by a source per unit time). Usually measured in lumens.

luminous intensity—Light intensity in a specified direction. The standard unit is called the international candle. Originally an ordinary wax candle was selected as the standard, and even today it is rated as having a luminous intensity of approximately one candle.

luminous sensitivity—1. In a phototube, the output current divided by the incident luminous flux at a constant electrode voltage. (The term "output current" here does not include the dark current.) 2. The sensitivity of an object to light from a tungsten-filament lamp operating at a color temperature of 2870°K. This definition is permissible, since luminous sensitivity is not an absolute characteristic but depends on the spectral distribution of the incident flux.

lumped—Concentrated at a single point.

lumped-constant elements—Distinct electrical units smaller than a wavelength. They are calibrated and used, in conjunction with other electrical/electronic equipment, for controlling voltage and current.

lumped-constant - tuned heterodyne-frequency meter—A device for measuring frequency. Its operation depends on the use of a tuned electrical circuit consisting of lumped inductance and capacitance.

lumped impedance—Impedance concentrated in a component, as distinguished from impedance due to stray or distributed effects.

lumped inductance—Inductance concentrated in a component, as opposed to stray or distributed inductance.

lumped loading—Inserting uniformly spaced inductance coils along the line, since continuous loading is impractical.

lumped parameter—Any circuit parameter which—for purposes of analysis—can be considered to represent a single inductance, capacitance, resistance, etc., throughout the frequency range of interest.

lux—A practical unit of illumination in the metric system. It is equivalent to the meter-candle and is the illumination on a one square-meter area on which there is a uniformly distributed flux of one lumen, or the illumination produced at a surface one meter from a source of one candle.

Luxemburg effect—A nonlinear effect in the ionosphere. As a result, the modulation on a strong carrier wave will be transferred to another carrier passing through the same region.

luxmeter—A type of illumination photometer employing a variable aperture and the contrast principle.

M

m—Abbreviation for the prefix milli-.

M—1. Symbol for mutual inductance. 2. Abbreviation for the prefix mega or meg meaning one million.

ma—Abbreviation for milliampere.

Ma—Abbreviation for megampere.

machine-available time—In a computer, power-on time less maintenance time.

machine cycle—The shortest complete process or action that is repeated in order. The minimum length of time in which the foregoing can be performed.

machine hardware—Circuits contained in the five parts of the computer: input, output, control, storage, and arithmetic sections; any other circuit is "off-line."

machine language—Also called computer code. A set of symbols, characters, or signs and the rules for combining them to convey instructions or data to a computer.

machine run—In a computer, the performance of one or more machine routines which are linked to form one operating unit.

machine sensible—Information in a form such that it can be read by a specific machine.

machine thermal relay—A device which functions when the temperature of an a-c machine armature, or of the armature or other load-carrying winding or element of a d-c machine, or converter, power rectifier, or power transformer (including a power-rectifier transformer) exceeds a predetermined value.

machine word—A unit of information consisting of a standard number of characters which a computer regularly handles in each register.

macrocode—A coding system which assembles groups of computer instructions into single code words and which therefore requires interpretation or translation so that an automatic computer can follow it.

macroprogramming—In a computer, the writing of machine-procedure statements in terms of macrocode instructions.

macroscopic—Large enough to be observed by the unaided eye.

macrosonics—The utilization of high amplitude sound waves for performing functions such as cleaning, drilling, emulsification, etc.

madistor—A semiconductor device that makes use of the effects of a magnetic field on a plasma current. The strength of a magnetic field determines the conductivity of the madistor material. A small change in the magnetic field produces a larger change in the madistor current.

MADT transistor—A microalloy diffused-base transistor.

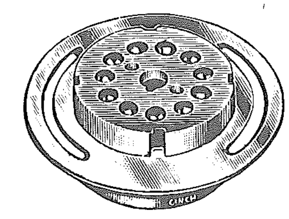
magamp—Abbreviation for magnetic amplifier.

magic eye—*See* Electron-Ray Tube.

magic-t—*See* Hybrid Junction.

magnaflux—A magnetic method of determining surface and subsurface defects in metals.

magnal base—An 11-pin base used on cathode-ray tubes.



Magnal socket.

magnal socket—An 11-pin socket used with cathode-ray tubes.

magnesium—An alkaline metal the compounds of which are sometimes used for cathodes.

magnesium anode—A bar of magnesium, buried in the earth, connected to an underground cable to prevent cable corrosion due to electrolysis.

magnesium cell—A primary cell the negative electrode of which is made of magnesium or one of its alloys.

magnesium-copper-sulphide rectifier—A dry disc rectifier consisting of magnesium in contact with copper sulphide.

magnesium-silver chloride cell—A reserve primary cell that becomes activated when water is added.

Magnesyn—Trade name for a device made by Bendix Aviation Corp. It is a portion of a repeater unit consisting of a two-pole permanent-manet rotor within a three-phase, two-pole, delta-connected stator. The rotor carries the indicating pointer and is free to rotate in any direction.

magnet—A body that has the property of attracting or repelling magnetic materials. In its natural form it is called a lodestone. It may also be produced by permanently magnetizing a piece of iron or steel. A temporary magnet—called an electromagnet—is produced by passing a current through a coil surrounding a piece of iron or steel; the magnetism persists only while current is flowing. When suspended freely, a magnet will turn and align its poles with the north and south magnetic poles of the earth. (*Also See* Electromagnetism *and* Permanent Magnet.)

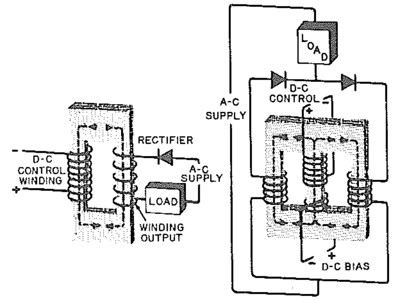
magnet brake—A friction brake controlled electromagnetically.

magnetic—Pertaining to magnetism.

magnetic aging—The normal change in the magnetic material resulting from gradual metallurgical change in the material. The term also applies when the metallurgical changes are accelerated by an increase or decrease in temperature. When used in reference to core loss, this term, unless otherwise modified, implies an increase in loss. When used in reference to permeability remanence, the term, in a positive sense, indicates a decrease in these quantities.

magnetic air gap—The air space, or nonmagnetic portion, of a magnetic circuit.

magnetically damped—A form of damping achieved by moving a metal vane through a magnetic field. This motion induces currents in the vane which set up magnetic fields opposing those of the stationary magnets, thus tending to bring the pointer to rest. This type of damping is found in many quality moving-iron and dynamometer-type instruments.



Magnetic amplifiers.

magnetic amplifier—Abbreviated magamp. A variable-impedance device by which load power and voltage can be controlled. Amplification occurs since the control source requires much less power than is supplied to the load.

magnetic analysis—The separation of a stream of electrified particles by a magnetic field, in accordance with their mass, charge, or speed. This is the principle of the mass spectrograph.

magnetic anisotropy—The dependence of the magnetic properties of some materials on direction.

magnetic-armature speaker—Also called a magnetic-armature loudspeaker or magnetic speaker. A speaker comprising a ferromagnetic armature actuated by magnetic attraction.

magnetic azimuth—Azimuth measured from magnetic north.

magnetic bearing—The position in which an object is pointing with respect to the earth's magnetic north pole. It is expressed in degrees clockwise from that pole.

magnetic bias—A steady magnetic field applied to the magnetic circuit of a relay.

magnetic biasing—The superimposing of another magnetic field on the signal magnetic field of a tape while a magnetic recording is being made.
